SUPPLEMENTARY METHODS

1. SNP Array Analysis

The aim was to identify the chromosomal alterations (gains, losses and copy-neutral loss-of-heterozygosity) occurring in adrenal nodules of patients with ACTH-independent macronodular adrenal hyperplasia.

SNP Array Experiments

500 ng of genomic DNA from adrenal nodules and leucocytes were hybridized to Affymetrix SNP6 chips according to the manufacturer recommendations at the Genomic Platform of the Cochin Institute (Paris, France). The chips were scanned with the Affymetrix GeneChip Scanner 3000 and the Affymetrix GeneChip Command Console Scan Controle 3.2.3.1515. The raw data and normalized data can be downloaded at the Gene Expression Omnibus website (www.ncbi.nlm.nih.gov/geo) under the GSE42171 accession number.

Generation of a Normalized aAnd Filtered B-Allele Frequency from Affymetrix SNP6

The genotype of each SNP is the combination of two alleles, arbitrarily called A and B. A SNP genotype can either be provided as a discrete value (genotypes "AA", "AB" or "BB"), or as a quantitative value called the B-allele frequency (BAF). The B-allele frequency is the proportion of the B allele in a given genotype, with a value measured around 0 for SNPs AA, around 1 for SNPs BB, and around 0.5 for heterozygous SNPs AB. The quantitative genotypes provided by the B-allele frequency are important for the sensitive detection of chromosomal regions with loss-of-heterozygosity in tumors[19].

B-allele frequencies were generated for each SNP with the allele-specific intensities ("signal A" and "signal B" from the Affymetrix Genotyping Console 4.0) and the discrete genotypes ("AA", "AB" or "BB") provided by the Affymetrix Genotyping Console 4.0 (Birdseed V2). For that aim, the genotype of each SNP was expressed in Cartesian coordinates from its signal A and its signal B, and then transformed into polar coordinates θ using the arctangent function (as shown in Figure S1, in the "Signal transformation" box of the "i. Calling LOH" panel). The "Signal transformation" box (Fig. S1) shows one SNP, each dot corresponding to the SNP genotype measured in one of our samples (adrenal nodules and leucocytes). For each SNP, the median centroid of each genotype in this Cartesian representation (black crosses named AA, AB and BB) and the origin of the plot define three reference directions, one for each genotype (θ_{AA}, θ_{AB} and θ_{BB}).

A noise reduction was then applied, to filter out the SNPs with the lowest ability to discriminate the different genotypes --this is important because SNPs within a somatic chromosomal alteration will show intermediate θ values, that are neither θ_{AA}, θ_{AB} nor θ_{BB}. For that aim, for any SNP with θ_{AB}- θ_{AA} lower than 0.45 radians, all the genotypes with θ lower than θ_{AB} were discarded, and for any SNP with a θ_{BB}- θ_{AB} lower than 0.45, all the genotypes with θ higher than θ_{AB} were discarded (approximately half of the genotypes were discarded).

Normalized B-allele frequencies were obtained by converting θ values to values between 0 and 1. For that aim, any genotype with θ lower than θ_{AA} was affected to 0, and any genotype with $\theta \geq \theta_{BB}$ was affected to 1. θ values between θ_{AA} and θ_{AB}, were transformed into values between 0 and 0.5 by linear interpolation. In a similar manner, θ values between θ_{AB} and θ_{BB}, were transformed into values between 0.5 and 1.

Detection of Somatic Chromosomal Alterations

Somatic loss-of-heterozygosity (LOH) and copy number (CN) alterations were identified using the SOMATICs method[19], following the general flow-chart presented in Figure S1. Briefly, two information were combined: the SNP genotypes, used for calling regions with loss-of-heterozygosity (see Fig. S1, "i. Calling LOH" panel), and the DNA copy number measured for each SNP, used for calling regions with copy-number alterations (see Fig. S1, "ii. Calling CN" panel).

Somatic loss-of-heterozygosity calls were based on the B-allele frequency (BAF), with detection of patterns of allelic imbalance. Indeed, when plotting the B-allele frequencies of heterozygous SNPs in chromosomal regions with allelic imbalance, the single band centered on 0.5 is replaced by two bands, as shown in the "Calling LOH segments" box and the "Filtering" box of the "i.Calling LOH" panel of Figure S1, and as described previously[19].

Copy number alteration calls (gains or losses) were based on the DNA copy number, quantified by the Log2Ratio.

Three detection algorithms were applied, depending on the size of the events to be detected:

a- For whole chromosome arms, patterns of allelic imbalance were automatically detected, easily confirmed visually on plots presenting the B-allele frequency of the SNPs along the genome. Losses were called when the mean Log2Ratio of the chromosome arm reached -0.1 or less. Gains were called when the mean Log2Ratio of the chromosome arm reached 0.1 or more. Otherwise, a copy-neutral loss-of-heterozygosity was called. The full set of altered chromosome arms is provided in the Table S2 ("SNP6_CNLOH_ChrArm") of this Supplementary appendix.

b- For large chromosome segments (but smaller than chromosome arms), allelic imbalance was first detected, based on the specific two-band pattern of allelic imbalance when plotting the B-allele frequencies along the genome (an example is provided in Fig. S1, in the "i. Calling LOH" panel, the "Calling LOH segments" box). These chromosome segments were then tested for potential copy number alterations. Calling a "loss" or a "gain" required a significant shift of the DNA copy number (an example is provided in the Fig. S1, in the "ii. Calling CN" panel, the "Calling CN segments" box), with a shift of the mean of Log2Ratios of at least 0.1, and with a t-test $p<0.05$ versus a normal chromosome. A copy-neutral loss-of-heterozygosity was called otherwise. To confirm the somatic origin of the alteration (and rule out a germline copy number variation), the chromosomal segment was tested in the corresponding leucocyte sample (when available), for the absence of allelic imbalance and of any significant shift in the DNA copy number. The full set of large chromosome segments with an alteration (somatic loss, gain or copy-neutral LOH) is provided in the Table S3 ("SNP6_CNLOH_segments") of this Supplementary appendix.

c- Small chromosome segments, were defined as those with insufficient informative SNPs (<10 heterozygous SNPs). For these segments, the allelic imbalance patterns detection could not be applied, and copy number alterations calls were based only on DNA copy number. For that aim, segments were first defined using a smoothed DNA copy-number value called the "CNState" (Affymetrix Genotyping Console V4.0). Any stretch of consecutive markers with a CNState differing from 2 copies of DNA was considered. Because this detection is far too sensitive, more stringent filters were then applied: the shift of the Log2Ratio had to reach a t-test $p<1e-10$ versus a normal chromosome, with no significant shift in the log2ratio for the same segment in the corresponding leucocyte DNA. When no matched leucocyte sample was available, a mean Log2ratio between 0.1 and 0.3 (for losses), and 0.1 and 0.2 (for gains) was requested. These values correspond to the mean Log2Ratios of large segments and chromosome arms with a somatic loss or a gain in our dataset. The full set of small chromosome segments with an alteration (somatic loss, gain or copy-neutral LOH) is provided in the Table S4 ("SNP6_CNnoLOHinfo_segments") of this Supplementary appendix.

Bioinformatics

These analyses were performed using R 2.15.0 and custom scripts derived from the SOMATICs method[19]. These scripts can be provided on request.

2. Microsatellite Analysis

Loss-of-heterozygosity on chromosome 16p was tested using 10 microsatellite markers (D16S521, D16S3024, D16S3134, D16S3082, D16S475, D16S3065, D16S3027, D16S423, D16S3135 and D16S3108). Primer sequences and PCR conditions were those provided by the National Center for Biotechnology Information (NCBI) *uniSTS* (STS stands for Sequence Tagged Sites) website (www.ncbi.nlm.nih.gov/unists). Fluorescent-labeled primers were used (Sigma-Aldrich Proligo, Saint Quentin Fallavier, France). Polymerase Chain Reactions (PCR) were performed using the Taq Gold (Applied Biosystems, Courtaboeuf, France). PCR products were migrated on a Beckman Ceq™ 8800 sequencer (Beckman Coulter, Fullerton, CA). Allelic peak heights were read with the Beckman Genetic Analysis System version 8.0 software. For each marker, the allelic ratios were determined in the leucocyte and in the adrenal nodules. A normalized ratio was obtained by dividing the allelic ratios of the leucocyte and of the adrenal nodule. Loss-of-heterozygosity was called for normalized ratios <0,6 or >1,66.

3. Whole Genome Sequencing

Five ACTH-independent macronodular adrenal hyperplasia nodules and their paired leucocyte were sequenced by Complete Genomics[20], starting from 10 µg of genomic DNA. The samples were processed through the Cancer Sequencing Service pipeline version 2.0.2.26, which includes an increased sequencing depth for the tumor samples, and a paired analysis with the matched leucocytes. Two types of variants called by Complete Genomics for each tumor were used for subsequent analysis, following the general flow-chart presented in Figure S2 of this Supplementary Appendix:

- the small variations (the "masterVar" file provided by Complete Genomics): this matrix reports all the SNPs, small deletions, insertions and more complex variations including only a few bases compared to the reference genome (NCBI built 37.2). Several filters were applied (Fig. S2), including the quality of the calls, the impact on proteins (variations that impact the protein only, including non-synonymous variations within the coding sequence, and splice-sites variations), and the compartment (somatic).
- the structural variants (the "somaticHighConfidenceJunctions" file provided by Complete Genomics): this file reports all the large deletions, inversions, translocations and other more complex structural variants called at the somatic level (in comparison to the germline sample). Only the junctions occurring within genes were considered. In addition, any junction that had already been identified in the 69 reference genomes sequenced with the same technique

(http://www.completegenomics.com/public-data/69-Genomes/) were discarded, because of the high probability of false positive call.

4. Sanger Sequencing of *ARMC5*

ARMC5 coding and flanking intronic sequences were amplified by PCR from tumor and leukocyte DNA. The following primers and conditions were used.

Exons	Amplicon	Primers sequence: forward (above), reverse (below)	annealing temperature	PCR product size
Exon 1	Amplicon 1a	GATTCTCCCTCGCCTCTTCT	60	491
		GAGCTTCTCACGCCTACCTC

Exon 6	Amplicon 6b	CTGCTGGCCGTTTCCTACTG	60	632
		GAACAAGACCCTGCTTGGTG		

5. Microarray Experiments and Analyses

Each tumor was snap frozen immediately after surgery and kept in liquid nitrogen until use. RNA extraction was performed as previously described[21] from 10 ACTH-independent macronodular adrenal hyperplasia tumor samples. Microarray experiments were performed as previously described, using Affymetrix U133 Plus 2.0 chips[21]. The full dataset can be found at Array Express (http://www.ebi.ac.uk/arrayexpress, experiment E-TABM-311). The accession numbers are CIT-HS-ACT-EC-AIMAH1, CIT-HS-ACT-EC-AIMAH5, CIT-HS-ACT-EC-AIMAH9, CIT-HS-ACT-EC-

AIMAH10, CIT-HS-ACT-EC-AIMAH11, CIT-HS-ACT-EC-AIMAH27, CIT-HS-ACT-EC-AIMAH74, CIT-HS-ACT-EC-AIMAH75, CIT-HS-ACT-EC-AIMAH76, and CIT-HS-ACT-EC-AIMAH77, corresponding to the samples H1, H5, H9,H10, H11, H27, H74, H75, H76 and H77 respectively.

All the transcriptome analyses were carried out using "R" (www.r-project.org). The transcriptome data was normalized using the Robust Multi-array Analysis (RMA) method (Affy package, www.bioconductor.org). Unsupervised hierarchical clustering was generated with the "hclust" function, using the "Euclidean" metrics and the "Ward" method, considering the top 1871 genes with the highest variation among the nodules of adrenal hyperplasia (coefficient of variation 0.2 or higher). The Linear Models for Microarray Data (LIMMA) test was used for the supervised group comparison of *ARMC5* mutated versus *ARMC5* non-mutated ACTH-independent macronodular adrenal hyperplasia (LIMMA R package, www.bioconductor.org). Multiple testing was corrected with the Benjamini-Hodgeberg false discovery rate assessment for all tests. The functional annotation of the differentially expressed gene (selected as those with an adjusted p-value <0.1) was performed with the Database for Annotation, Visualization and Integrated Discovery (DAVID) v6.7 (http://david.abcc.ncifcrf.gov/), using Gene Ontology annotations (http://www.geneontology.org/).

6. siRNA Experiments: siRNA Sequences

The following sequences were used:

siRNA		sequence
ARMC5	siARMC5-1	GACAGACAGCATCCAGAAC
	siARMC5-2	CTTAGCCATGGAACCTGAG
	siARMC5-3	GGATGAATTGGCTGTGAAG
	siARMC5-4	CCATTCTGATCCTCGCCAA
Control	siCtr	GCGAGCAACCGAACCTAAA

7. Reverse Transcription Quantitavite Polymerase Chain Reaction (RT-qPCR) Experiments: Primer Sequences

The following sequences were used:

Gene		Primers	annealing temperature	PCR product size
ARMC5	Forward	CTCGGAGGCATACTCCCTTT	60	68
	Reverse	GTTCGGTTCTGGATGCTGTC		
NR5A1	Forward	AGCAGAAGAAGGCACAGATTCG	60	110
	Reverse	CTGGGAGGCAGCACGTAGTC		
NR0B1	Forward	CAAATGCTGGAGTCTGAACATCA	60	116
	Reverse	ACTGGAGTCCCTGAATGTACTTCAC		
MC2R	Forward	GCCCAGAAAGTTCCTGCTTCAG	64	157
	Reverse	TCTCCTGCTTGTGGTTAAGGCG		
CYP17A1	Forward	GCCCCATCTATTCGGTTCGTA	60	169
	Reverse	GAGTCAGCGAAGGCGATACCC		
CYP21A2	Forward	CCTTCGGAGACAAGATCAAGGA	60	109
	Reverse	TCACGTCCACAATTTGGATGG		
CYP11A1	Forward	TGTATGAGATGGCACGCAACC	58	227
	Reverse	CAGTGTCTTGGCAGGAATCAT		

8. Western Blot Experiment: Antibodies

The following antibodies were used:

Antibodies			
Antibodies	dilution		reference
	Western-blot	IHC	
anti-GAPDH	1/2500		SC-25778 (Santa Cruz)
anti-Cleaved LAMIN A/C	1/1000		2032S (Cell Signalling)
anti-β-ACTIN	1/2500		A-2066 (Sigma-Aldrich)
anti-cleaved-caspase3		1/200	D9661 (cell signalling)
anti-ARMC5	1/1000	1/25	Abnova PAB23822
anti-Flag M2		1/200	F-1804 (Sigma-Aldrich)
anti-CYP11A1		1/750	sc-18040 (Santa Cruz)
peroxydase-conjugated anti-rabbit	1/5000		7074S (cell signalling)
peroxidase-conjugated anti-mouse	1/5000		SC-2005 (Santa Cruz)
alexia fluor 488 goat anti-rabbit		1/400	A11008 (Life technology)
alexia fluor 568 goat anti-mouse		1/400	A11004 (Life technology)

9. Immunohistochemistry

Immunohistochemistry was performed on serial sections of the same tissues. Sections were deparaffinized in xylene and rehydrated through 100% ethanol. For antigen unmasking, the slides were incubated in citrate buffer pH6 for 40 min at 99° C. Endogenous peroxidases were inhibited by incubation in 3% hydrogen peroxide (Sigma-Aldrich, St. Louis, MO) in water for 5 min. Primary antibodies against ARMC5(1:25) and CYP11A1(1:750) were incubated overnight at 4 C. Bond Polymer Refine Detection (ref DS9800 - Ménarini-Leica) was used for antigen detection. Sections were washed; incubated 10 min with Post Primary IgG linker reagent localizes mouse antibodies. Than with Poly-HRP IgG reagent localizes rabbit antibodies for 10 min. The slides were developed using diaminobenzidin and counterstained with hematoxilin (Sigma) and blue in saturated Lithium carbonate for 20 seconds.

10. Fluorescence Immunostaining

Culture cells were fixed in chilled methanol/acetone solution (vol/vol) for 10 min followed by 5 min permeabilization with 0.2% Triton™ X-100 (Sigma, MO, USA). Blocking was performed at room temperature for 30 min with 10% horse serum. Samples were incubated in primary antibodies , cleaved caspase 3 Ab (1/200), Flag Ab (1/200) ON at°C and secondary antibodies , Alexia fluor 568 goat anti mouse (1/400, Life thecnology), alexia fluor 488 goat anti rabbit (1/400, Lifetechnonoly) for 1h at room temperature. Every time after incubation with antibody, the samples were washed three times with phosphate buffered saline. The nuclei were stained with DAPI and after mounting with Fluoromount G™ (DAKO), images were taken with a fluorescence microscope (BX-41; Olympus, Japan).

Figure S1: Flowchart of the SNP Chips (Affymetrix SNP6) Data Analysis

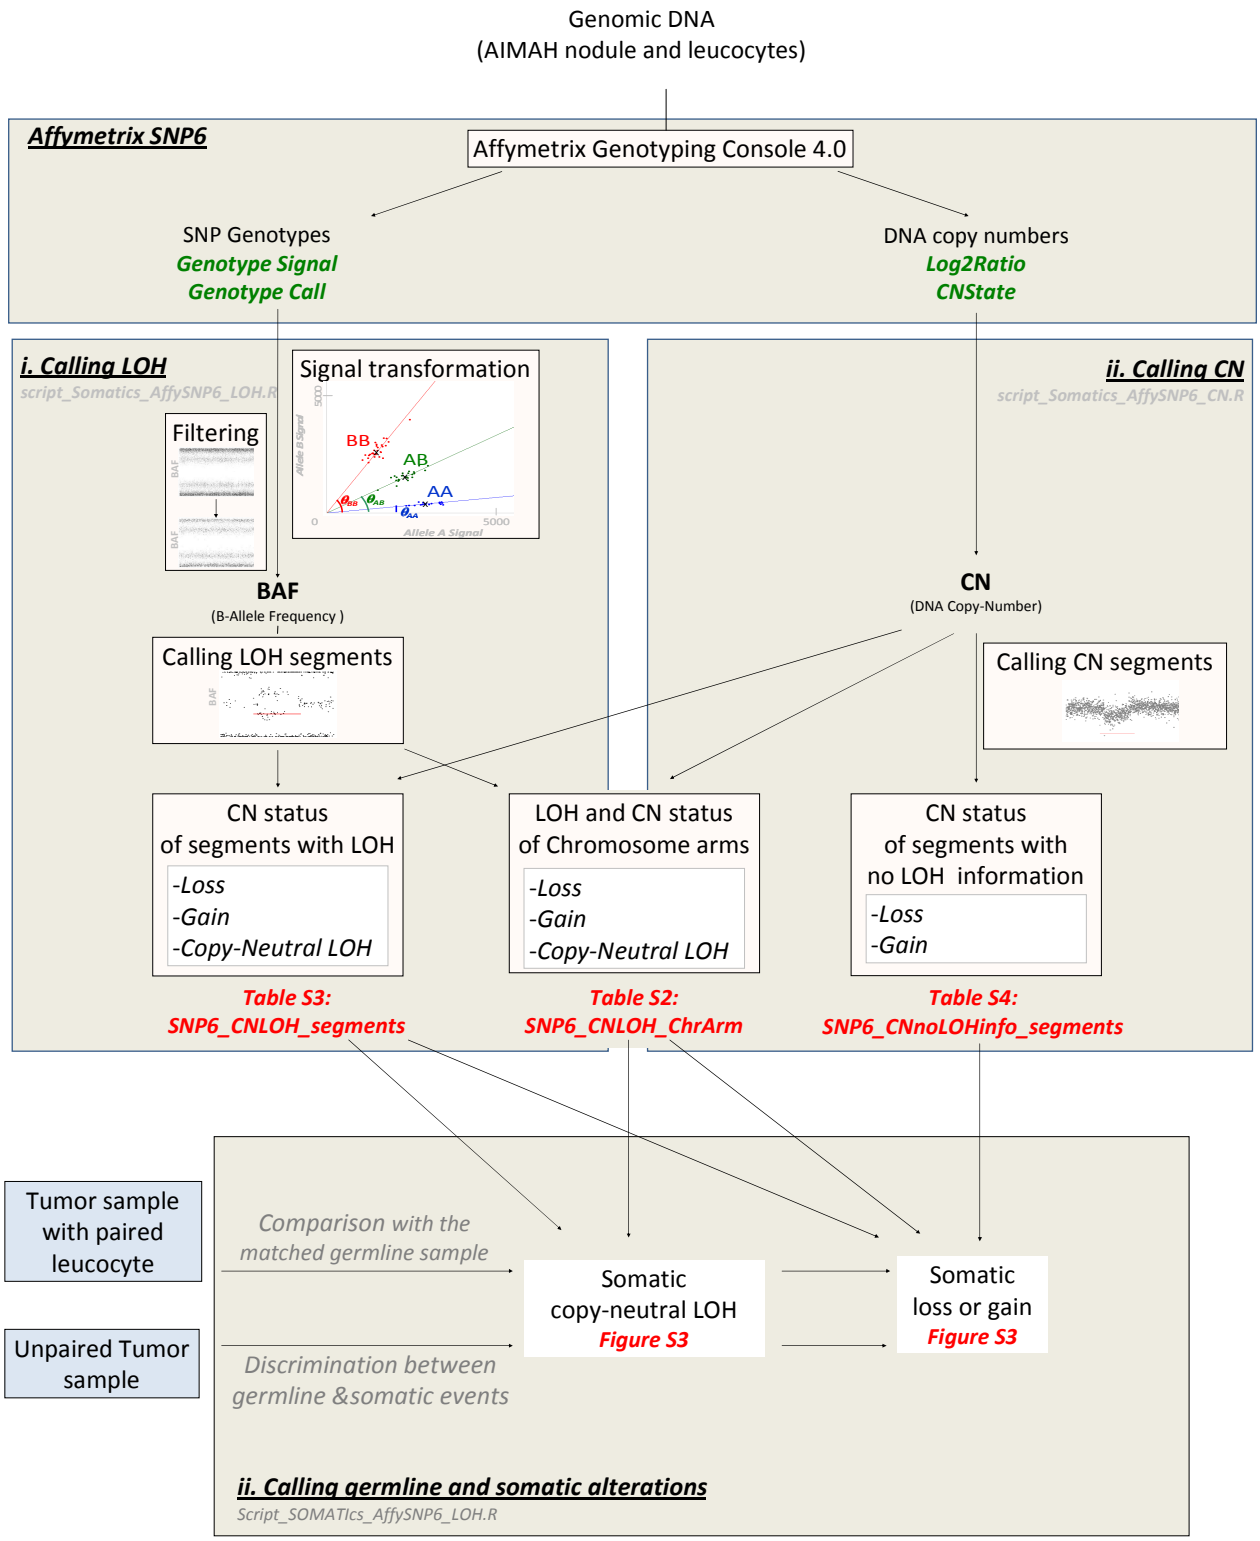

Figure S2: Flowchart of the Whole Genome (Complete Genomics) Data Analysis

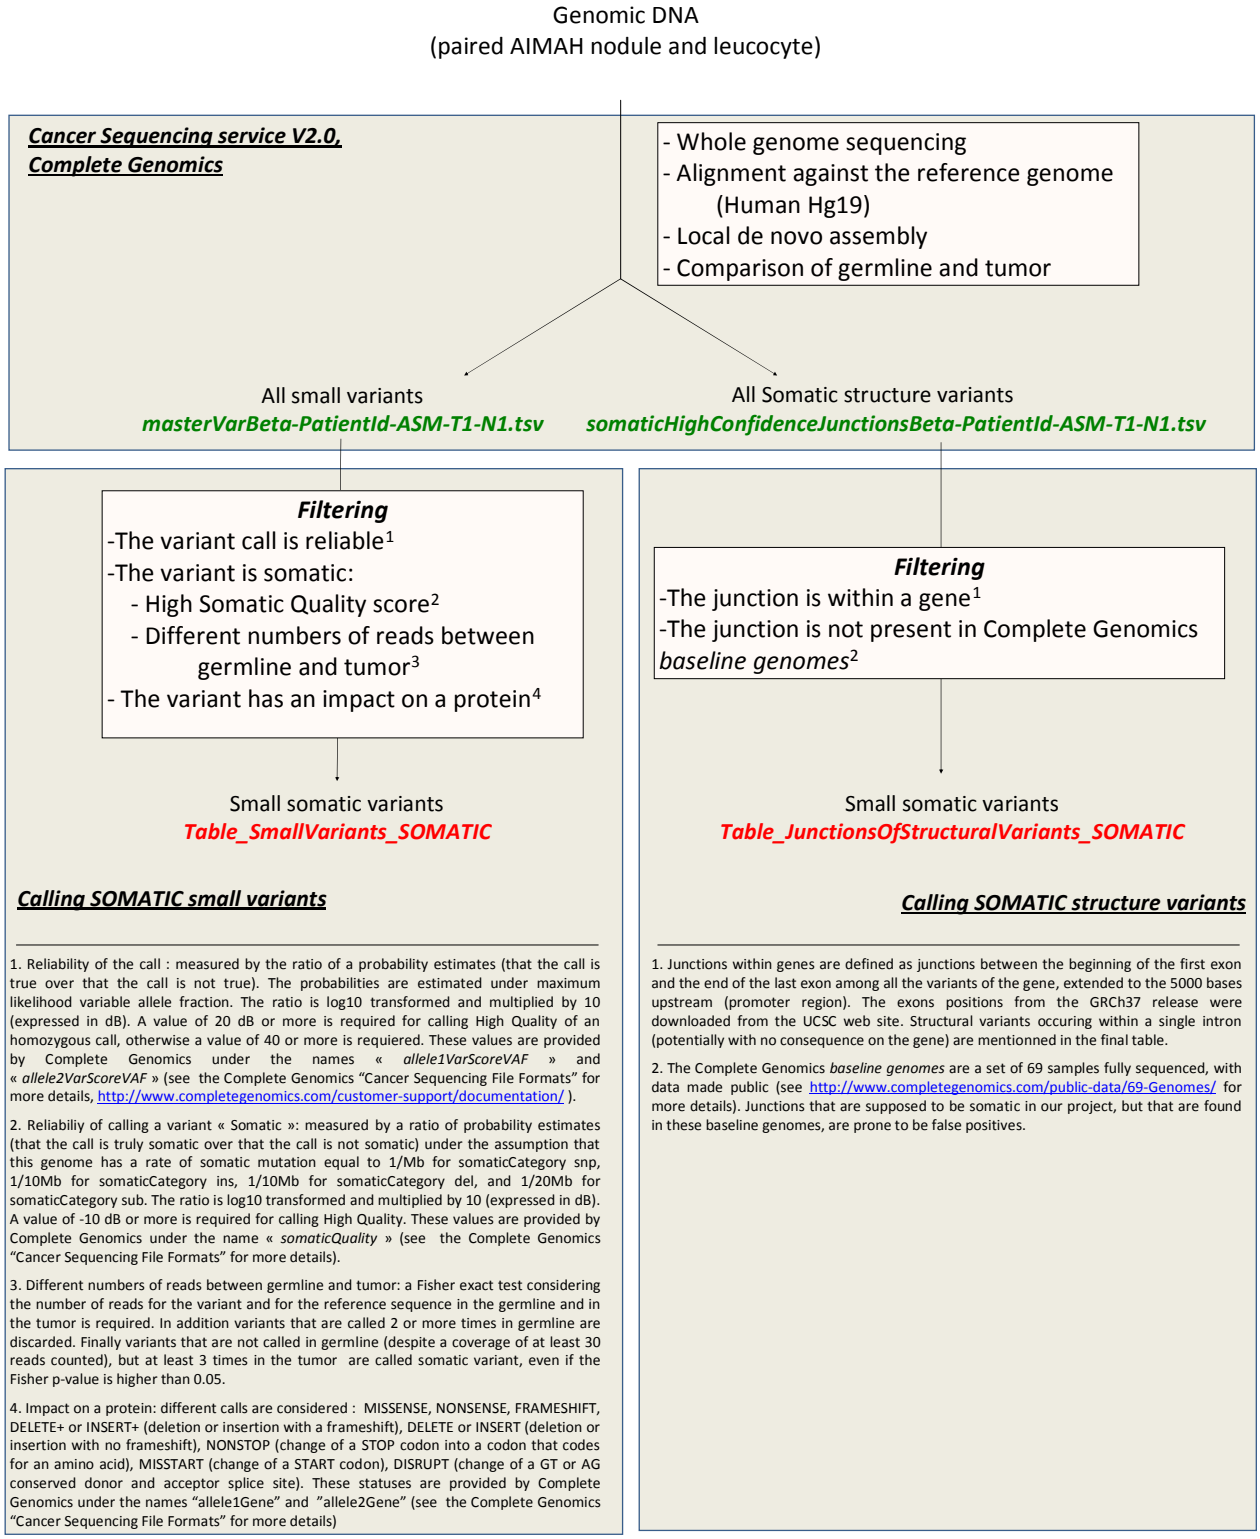

1. Reliability of the call : measured by the ratio of a probability estimates (that the call is true over that the call is not true). The probabilities are estimated under maximum likelihood variable allele fraction. The ratio is log10 transformed and multiplied by 10 (expressed in dB). A value of 20 dB or more is required for calling High Quality of an homozygous call, otherwise a value of 40 or more is requiered. These values are provided by Complete Genomics under the names « *allele1VarScoreVAF* » and « *allele2VarScoreVAF* » (see the Complete Genomics "Cancer Sequencing File Formats" for more details, http://www.completegenomics.com/customer-support/documentation/).

2. Reliabiliy of calling a variant « Somatic »: measured by a ratio of probability estimates (that the call is truly somatic over that the call is not somatic) under the assumption that this genome has a rate of somatic mutation equal to 1/Mb for somaticCategory snp, 1/10Mb for somaticCategory ins, 1/10Mb for somaticCategory del, and 1/20Mb for somaticCategory sub. The ratio is log10 transformed and multiplied by 10 (expressed in dB). A value of -10 dB or more is required for calling High Quality. These values are provided by Complete Genomics under the name « *somaticQuality* » (see the Complete Genomics "Cancer Sequencing File Formats" for more details).

3. Different numbers of reads between germline and tumor: a Fisher exact test considering the number of reads for the variant and for the reference sequence in the germline and in the tumor is required. In addition variants that are called 2 or more times in germline are discarded. Finally variants that are not called in germline (despite a coverage of at least 30 reads counted), but at least 3 times in the tumor are called somatic variant, even if the Fisher p-value is higher than 0.05.

4. Impact on a protein: different calls are considered : MISSENSE, NONSENSE, FRAMESHIFT, DELETE+ or INSERT+ (deletion or insertion with a frameshift), DELETE or INSERT (deletion or insertion with no frameshift), NONSTOP (change of a STOP codon into a codon that codes for an amino acid), MISSTART (change of a START codon), DISRUPT (change of a GT or AG conserved donor and acceptor splice site). These statuses are provided by Complete Genomics under the names "allele1Gene" and "allele2Gene" (see the Complete Genomics "Cancer Sequencing File Formats" for more details)

1. Junctions within genes are defined as junctions between the beginning of the first exon and the end of the last exon among all the variants of the gene, extended to the 5000 bases upstream (promoter region). The exons positions from the GRCh37 release were downloaded from the UCSC web site. Structural variants occuring within a single intron (potentially with no consequence on the gene) are mentionned in the final table.

2. The Complete Genomics *baseline genomes* are a set of 69 samples fully sequenced, with data made public (see http://www.completegenomics.com/public-data/69-Genomes/ for more details). Junctions that are supposed to be somatic in our project, but that are found in these baseline genomes, are prone to be false positives.

Figure S3: Chromosomal Alterations in ACTH-Independent Macronodular Adrenal Hyperplasia Nodules Identified with SNP Arrays

Panel A shows the chromosomal gains (pink), losses (blue) and copy-neutral loss-of-heterozygosity (yellow) along the genome in each ACTH-independent macronodular adrenal hyperplasia nodule. For some patients (1,17, 6 and 44), several nodules were included. Chromosomal losses in 1p, and 18q, gains in 1q and copy-neutral loss-of-heterozygosity in 16p are the most frequent events. Panel B shows for each region of the genome the number of patients having a chromosomal alteration in at least one of their ACTH-independent macronodular adrenal hyperplasia nodules. The most common event is the copy-neutral loss-of-heterozygosity in 16p, found in seven of 26 patients. Panels C to L show the chromosome 16 of the ACTH-independent macronodular adrenal hyperplasia nodules with a copy-neutral loss-of-heterozygosity in 16p. The upper part of each panel shows the genotypes of the SNPs expressed as the proportion of minor allele B in the genotype (B-allele frequency or BAF): SNPs of genotype "AA", "BB" and "AB" have a BAF of 0, 1 and 0.5, respectively. In the yellow regions (16p), the normal band of heterozygous SNPs "AB" has been lost, and has been replaced by two bands with BAF values in the 0 to 0.5 and 0.5 to 1 intervals, corresponding to loss-of-heterozygosity (LOH) events. The lower part of each panel shows the DNA copy-number along the chromosome 16, expressed in log-scale (logR), with the red line corresponding to two copies of DNA. In the regions with loss-of-heterozygosity, the DNA copy number is not altered (two copies remain), showing that the loss-of-heterozygosity is copy-neutral.

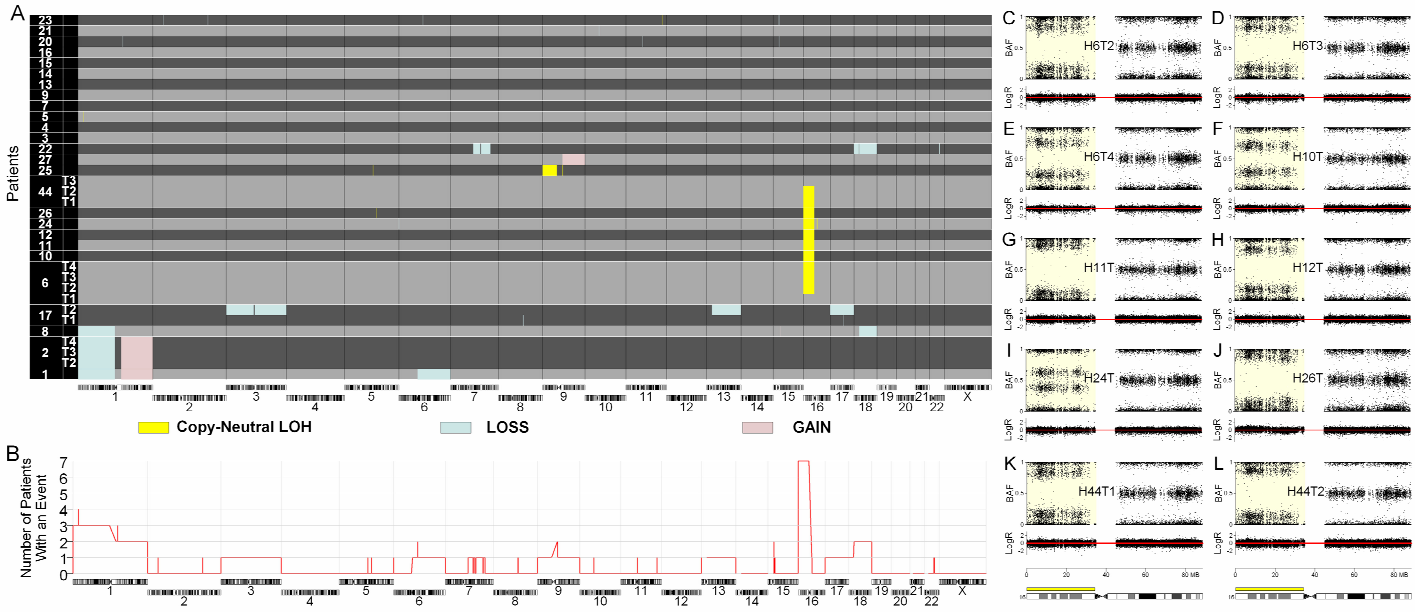

Figure S4: Location of the *ARMC5* Mutations

The sites in the ARMC5 protein of the various genetic alterations found on the tumor DNA are shown.

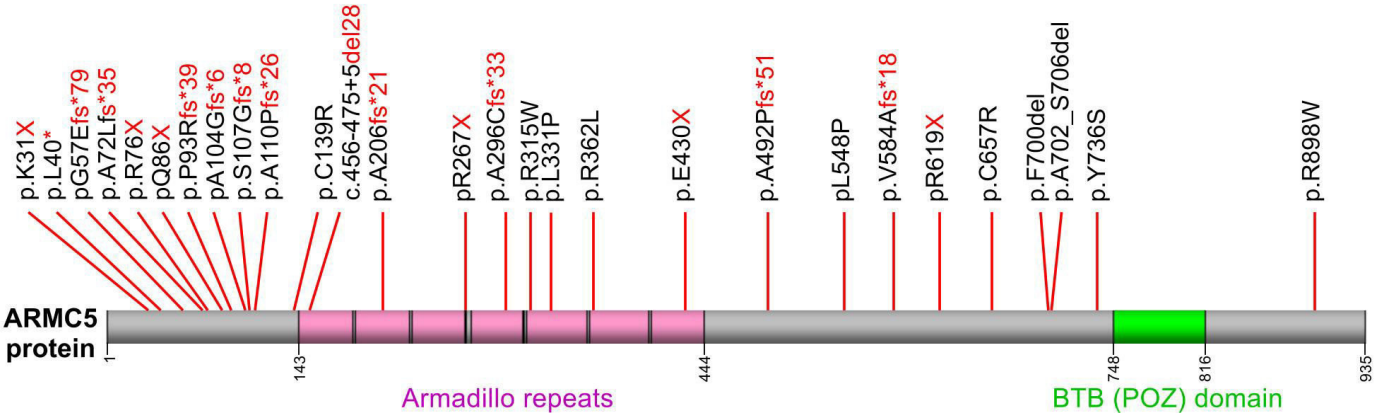

Figure S5: Germline Microdeletion in a Patient Including the *ARMC5* Locus

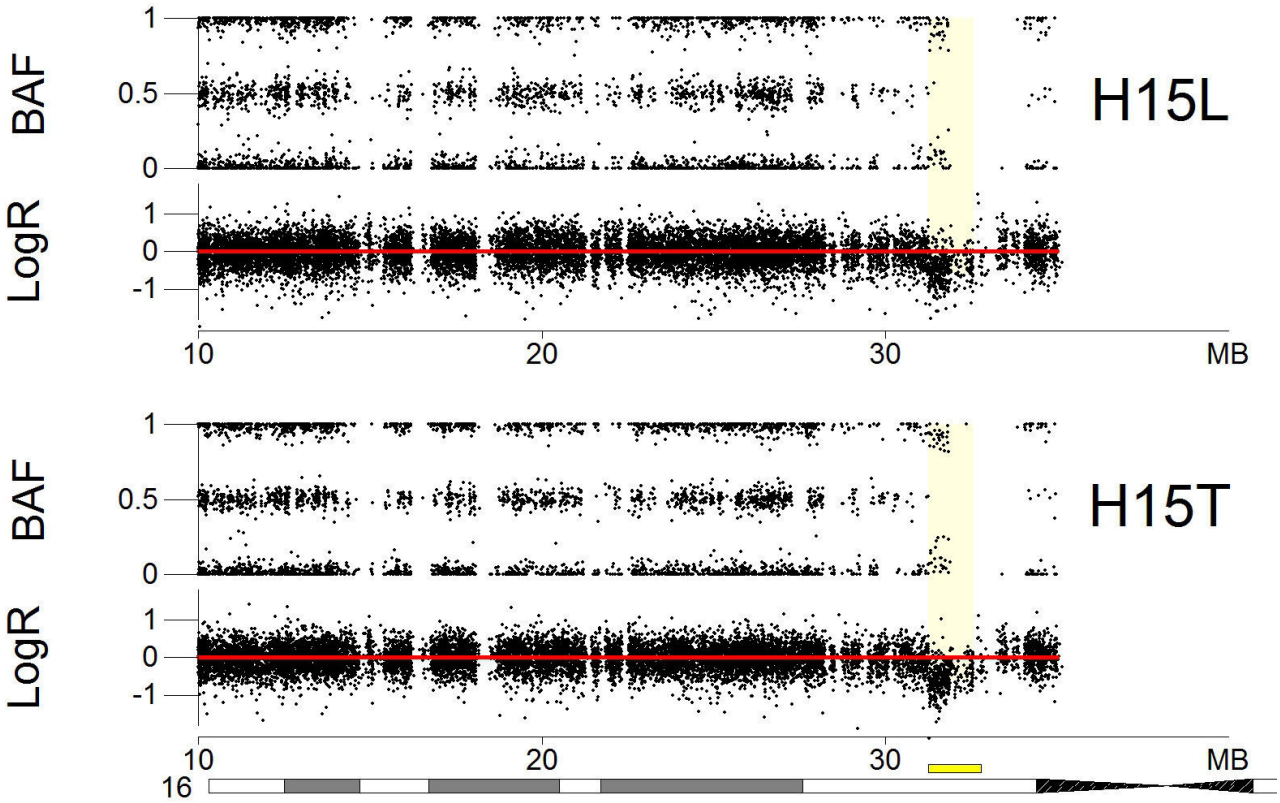

Figure S6: the *ARMC5* Mutations are Present on two Different Alleles

For two tumors H7T and H25T, the two mutations were close enough to belong to the same amplicon. In order to determined if the mutations were present on the two different alleles, PCR products were cloned in the pGEM-T-Easy vector (Promega) and transformed in DH5 bacteria (Life Technologies). Ten clones were sequenced for each tumor, showing that the two mutations were present on two different alleles.

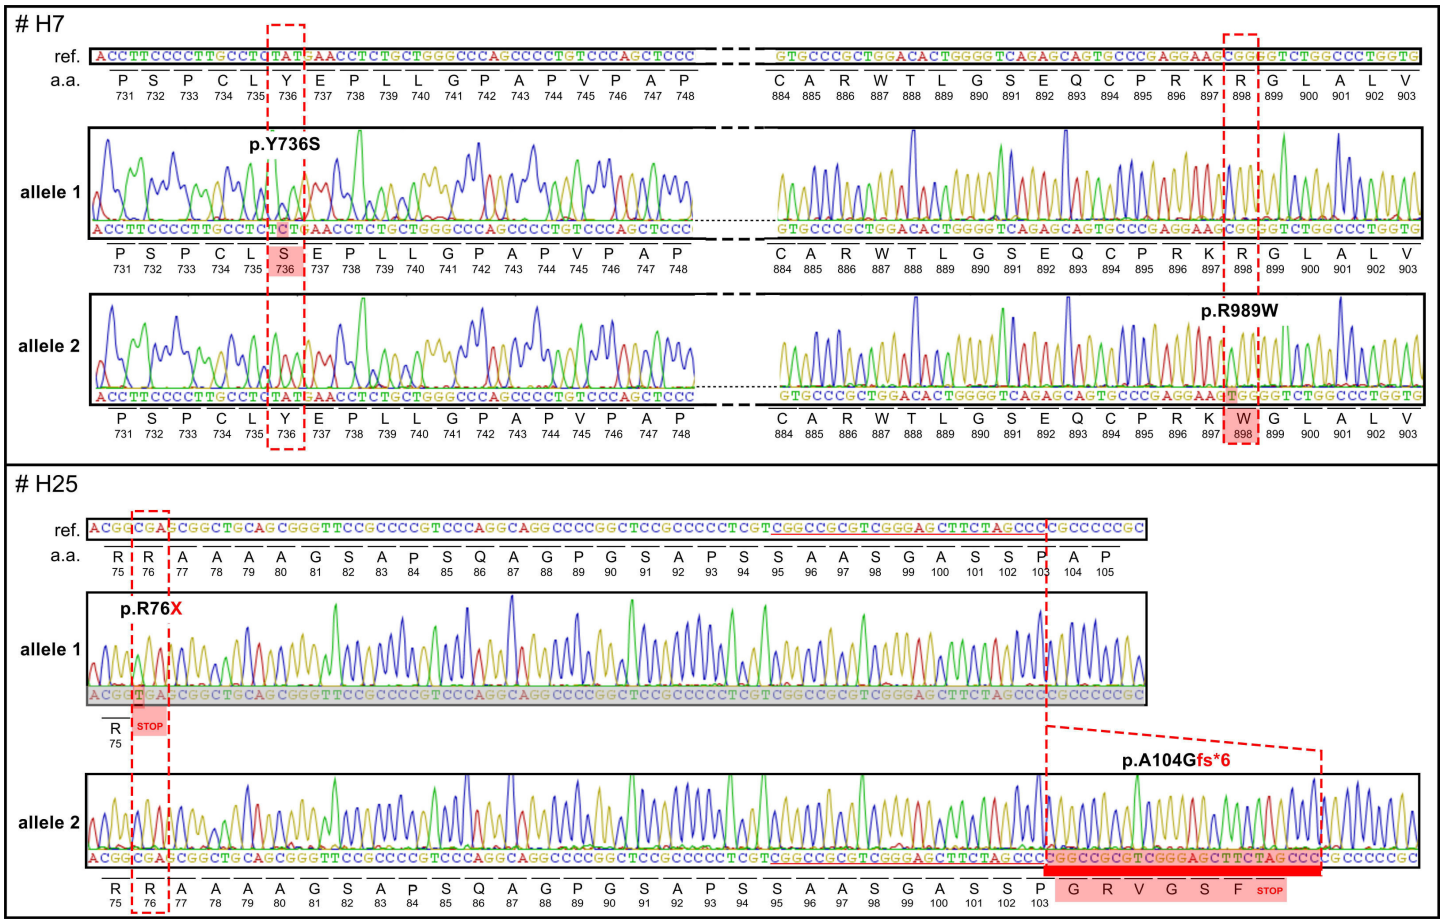

Figure S7: Sequencing *ARMC5* in Inter-Nodular Regions

The coding and flanking intronic sequences of *ARMC5* were sequenced in inter-nodular regions of 4 different AIMH from patient with *ARMC5* mutation.

Only the germline mutation was found. No somatic second hit could be identified, and the heterozygous status of each mutant indicates the abscence of loss-of-heterozygosity as a second event.

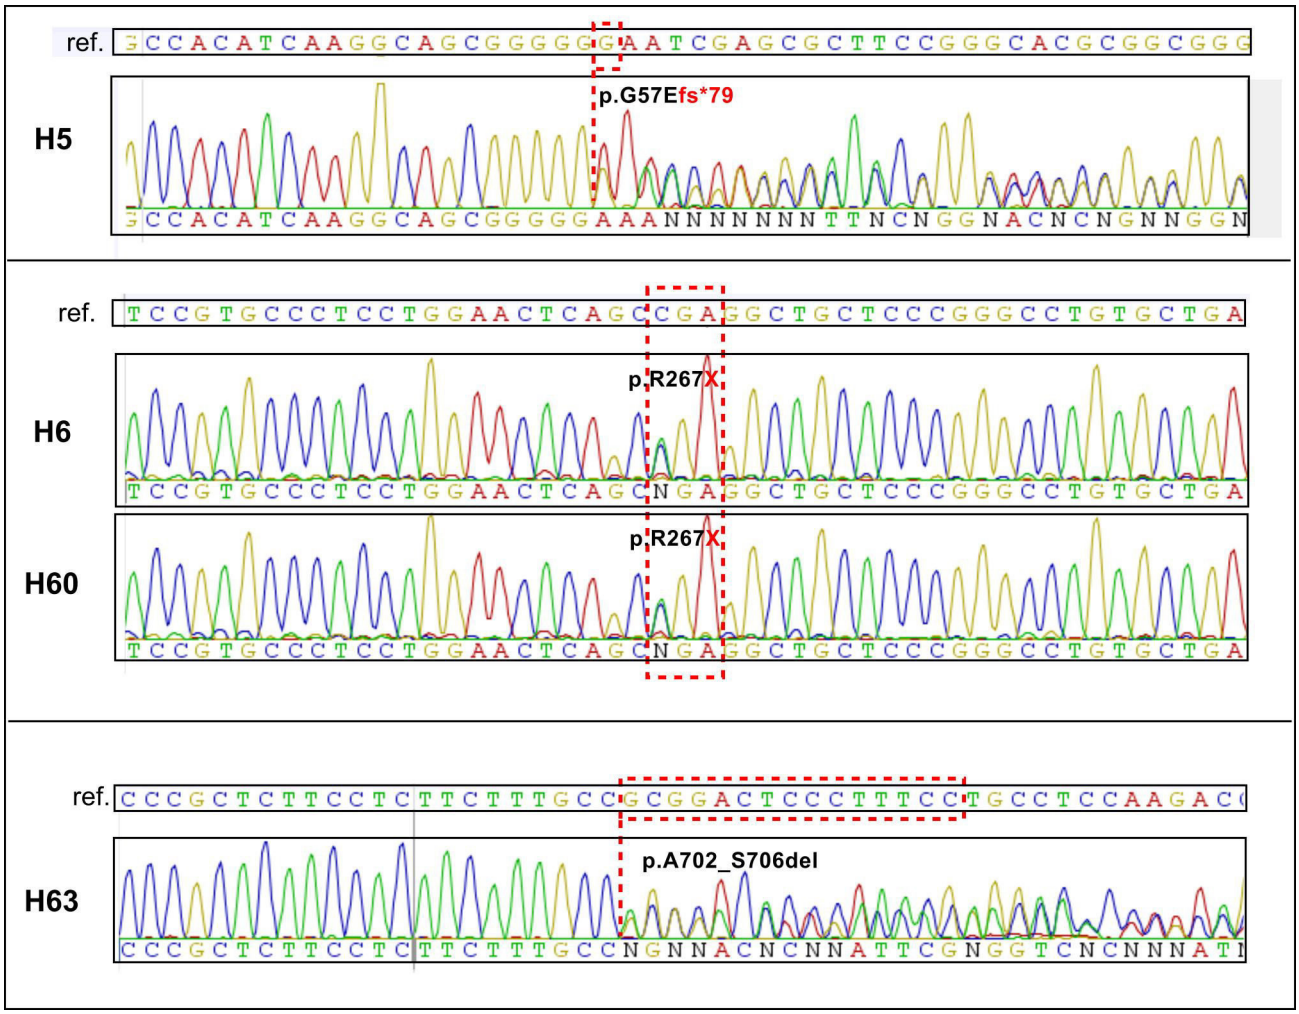

Figure S8: Unsupervised Hierarchical Clustering of the ACTH-Independent Macronodular Adrenal Hyperplasia Transcriptome

Unsupervised hierarchical clustering of the ACTH-independent macronodular adrenal hyperplasia transcriptome (performed blind to the *ARMC5* mutation status). The patients are separated into two groups, with *ARMC5* mutations (M) in one, and the wild type (WT) *ARMC5* in the other.

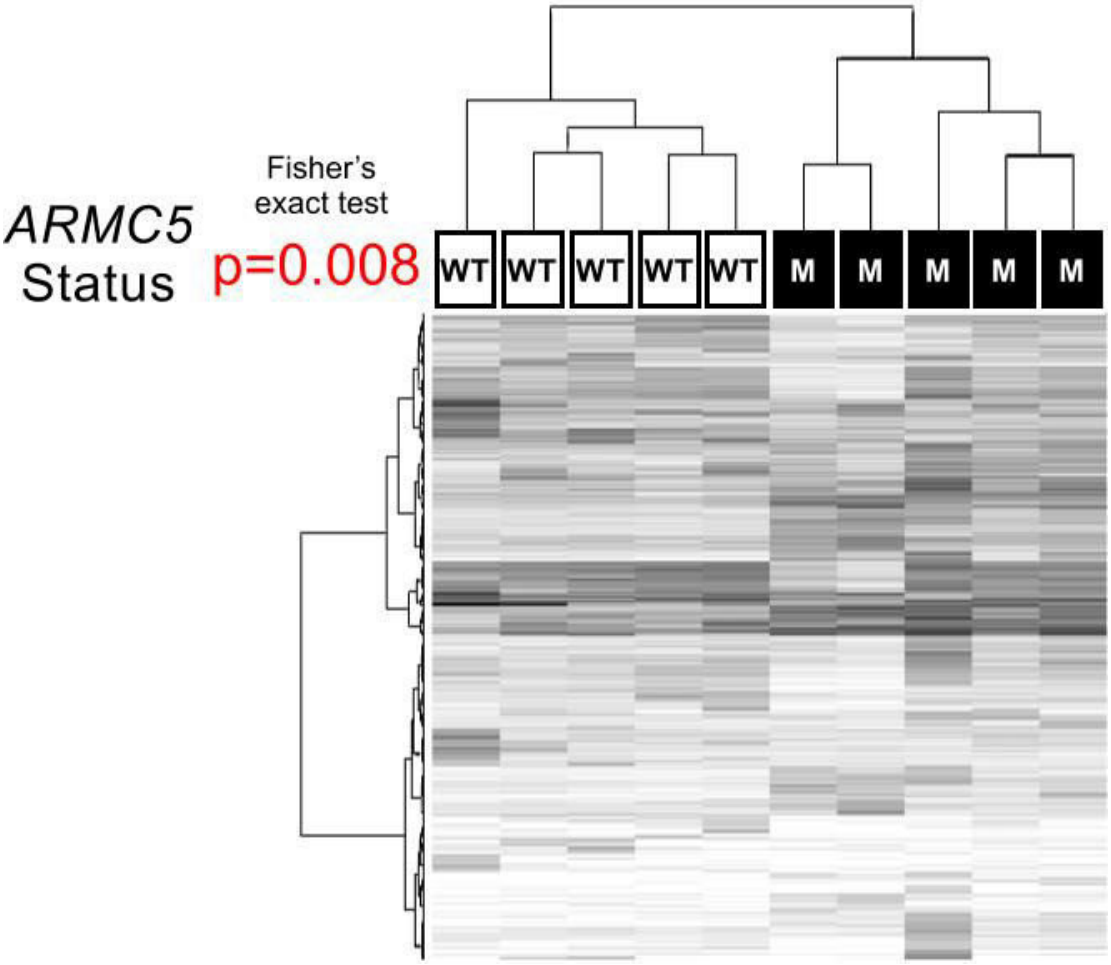

Figure S9: Immunohistochemistry of ARMC5

Panel A: Immunohistochemistry of ARMC5 (middle panel) and CYP11A1 (right panel) proteins, shows expression a membranous and cytoplasmic expression of ARMC5 and CYP11A1 in the normal adrenal cortex and in an ACTH-independent macronodular adrenal hyperplasia nodule with no *ARMC5* mutation, contrasting with a decreased expression of ARMC5 and CYP11A1 in an ACTH-independent macronodular adrenal hyperplasia nodule with a germline *ARMC5* nonsense mutation. Panel B : Immunocytochemistry of ARMC5 in H295R and Hela cell lines shows a membranous and cytoplasmic expression. Panel C: The expression of CYP11A1 is decreased at the mRNA level after *ARMC5* inactivation by siRNA in the adrenocortical H295R cells .

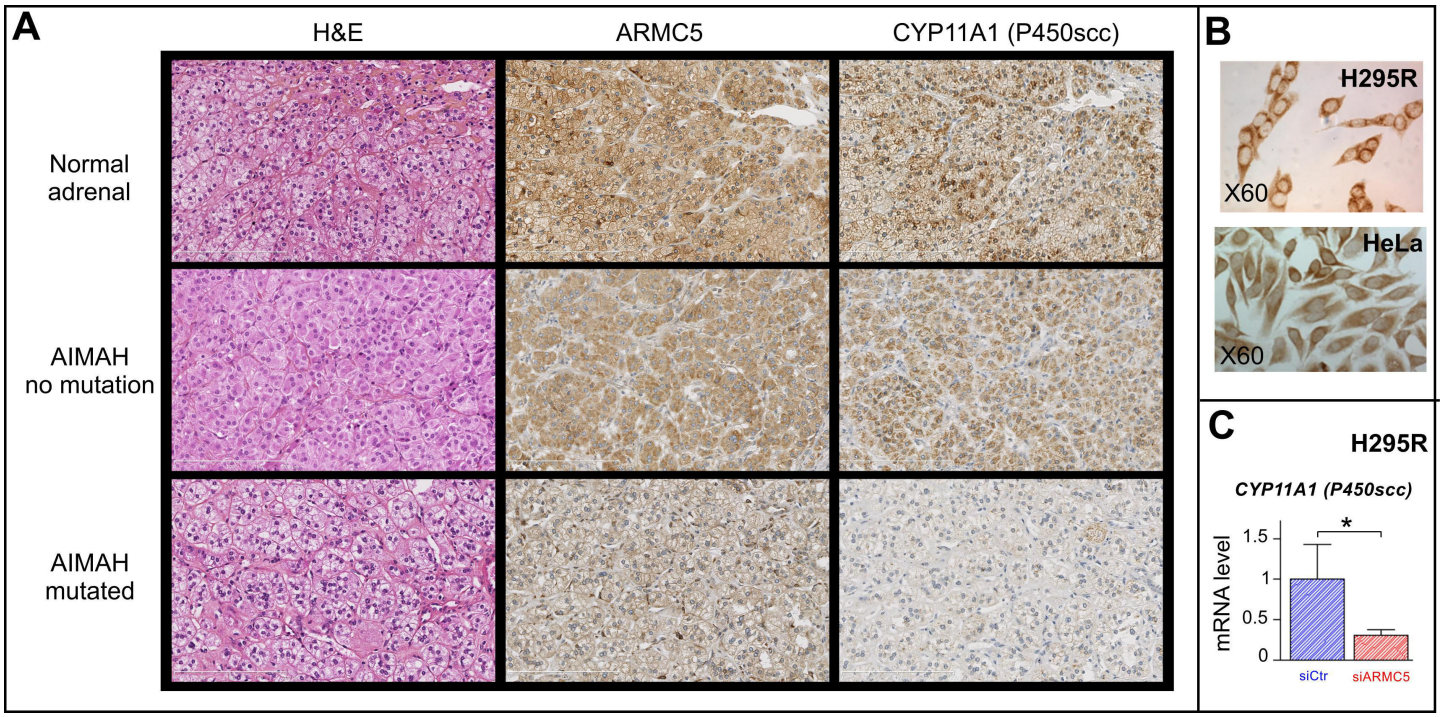

Figure S10: Expression of ARMC5 in HeLa Cells

Immunofluorescence staining of transfected HeLa cells with different flagged ARMC5 constructs [a wild-type and two missense mutants : p.R898W and p.L548P]. Red staining corresponds to the Flag antibodies (targeting the ARMC5 constructs), green staining to the cleaved-caspase3 antibodies (detection of apoptosis), and blue staining to dapi (detection of cells nuclei). After 6 hrs the cells expressing the ARMC5 construct (both the wild type and the mutants) have a normal morphology. After 14 hrs, the cells expressing the wild type ARMC5 construct (indicated by the white arrows) are apoptotic, as suggested by the co-expression of the cleaved-caspase 3, and by the altered cell morphology with condensed nuclei. By contrast, the cells expressing the missense ARMC5 constructs (p.R898W and p.L548P) do not co-express cleaved-caspase, nor present any altered morphology.

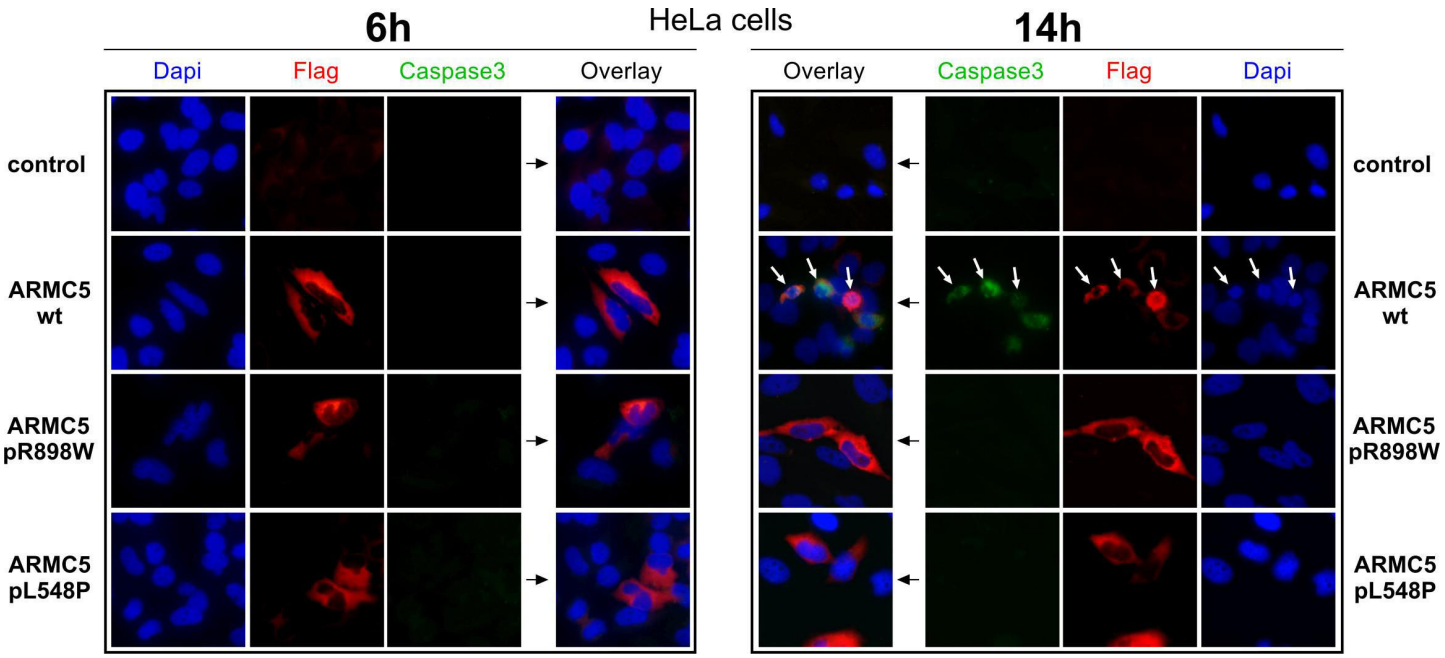

Figure S11: Decreased Apoptosis Associated with *ARMC5* Mutations

Western blot of H295R cells tranfected with the empty control vector, wild type ARMC5 and the two ARMC5 mutants pR898W and pL548P. The expression of the wild type ARMC5 increased the cleaved-PARP and cleaved-Lamin A/C levels, suggesting induction of apoptosis, while the mutants did not.

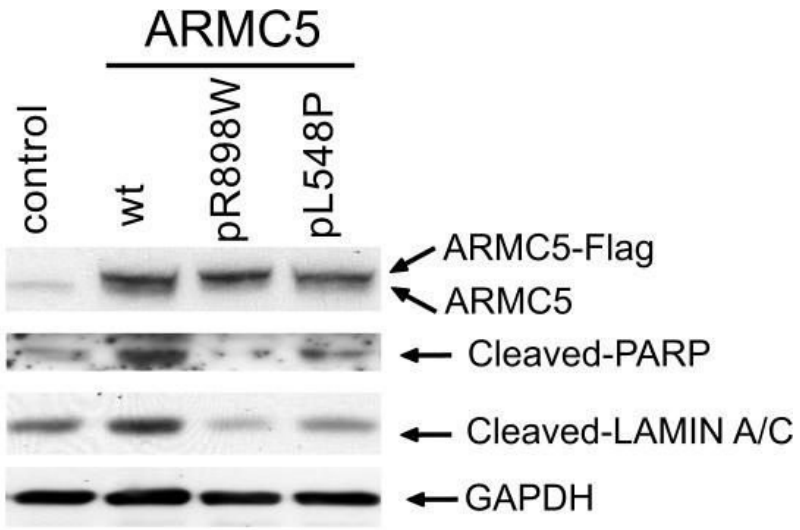

Table S1: Patients Characteristics

This table includes the clinical data of Table 1 with more detailed endocrine characteristics, including the illegitimate responses, the mineralocorticoid and the androgene profiles of each patient.

*** p<0.05**
 # quantitative variables are expressed as mean and 95% confidence interval; qualitative variables are expressed as numbers of patients

Table S2. SNP6_CNLOH_ChrArm: Alterations in Chromosome Arms

Chromosome gains, losses and copy-neutral loss-of-heterozygosity (LOH) are provided at the chromosome arm level.

[1]. Mean of the B-allele frequency of the heterozygous SNPs in the region with loss-of-heterozygosity. Values between 0.5 and 1 are transformed to fit the 0 to 0.5 interval by the formula 1-BAF.

[2]. Number of SNPs detected as heterozygous by Somatics.

[3]. The p-value is generated by a two-sided Student T-test comparing the Log2Ratio of the markers in the segment with loss-of-heterozygosity and the Log2Ratio of the markers in the reference (e.g. unaltered) chromosome from the same sample. In this study, the chromosome 2 was chosen for all tumors as the reference chromosome.

Table S3: SNP6_CNLOH_segments: Alterations in Large Chromosome Segments (but Smaller than a Chromosome Arm)

Chromosome alterations (gains, losses and copy-neutral loss-of-heterozygosity) are provided at the level of chromosome segments smaller than a chromosome arm. These alterations are identified by a loss-of-heterozygosity, with or without copy number alteration.

[1]. Mean of the B-allele frequency of the heterozygous SNPs in the region with loss-of-heterozygosity. Values between 0.5 and 1 are transformed to fit the 0 to 0.5 interval by the formula 1-BAF.

[2]. Number of SNPs detected as heterozygous by Somatics.

[3]. The p-value is generated by a two-sided Student T-test comparing the Log2Ratio of the markers in the segment with loss-of-heterozygosity and the Log2Ratio of the markers in the reference (e.g. unaltered) chromosome from the same sample. In this study, the chromosome 2 was chosen for all tumors as the reference chromosome.

[4]. The CopyNumber State (CN_State) is the mean of DNA copy number estimates at each marker provided by Affymetrix Genotyping Console

[5]. The same segment is measured in the germline sample paired with the tumor (when available), to ensure that the alteration is not present in germline.

Table S4: SNP6_CNnoLOHinfo_segments: Alterations in Small Chromosomal Segments

Chromosome alterations (gains and losses) are provided at the level of small chromosome segments (defined as showing less than 10 informative heterozygous SNPs). These alterations are identified by copy number alterations only (no loss-of-heterozygosity can be called).

[1,2,3,4,5]: See Supplemental Table 3 legend.

Table S5: Microsatellite Analysis of 16p

Short allele: peak height of the short allele (values are fluorescence intensities).

Long allele: peak height of the long allele (values are fluorescence intensities)

Ratio: normalized ratio, obtained by dividing the allelic ratios (short allele over long allele) of the leucocyte and the tumor. The normalized ratios >0.6 or <1.6 are highlighted in yellow.

MSI: incalculable (because of microsatellites instability)

NA: not available

HOMO: homozygous marker

The normalized ratios >0.6 or <1.6 are highlighted in yellow.

Table S6 : Whole Genome Sequence Samples

[1]. Values about the coverage were directly extracted from the Complete Genomics "summary-*sample*-ASM-T1.tsv" file, with no filtering.

[2]. The total variation counts were mainly extracted from the Complete Genomics "summary-*sample*-ASM-T1" file, with no filtering. The "number of structural variants within genes" was counted from the Complete Genomics "somaticHighConfidenceJunctionsBeta-PatientId-ASM-T1-N1.tsv" file, filtering the junctions that fall into the genes loci, including the 5000 bases upstream.

[3]. The somatic variation counts were performed after extracting all the variants of high somatic quality as defined by Complete Genomics (tag "SQHIGH"). These variants were directly extracted from the "masterVarBeta-PatientId-ASM-T1-N1.tsv" file. No extra filtering was applied for these counts.

		Coverage[1]								Total variation[2]												Somatic variation[3]

Table S7 : List of Small Somatic Variants Identified by Whole Genome Sequencing.

These variants include SNPs, Small eletions, insertions, and substitutions.

[1]. This column specificies the zygosity (heterozygous, haploid and half when one allele is not called), and the variation type (SNP, deletion, insertion, substitution).

[2]. One Polyphen (http://genetics.bwh.harvard.edu/pph2/, version 2.2.2) score is provided for each UniProt Id.

[3]. Sift prediction are provided for each locus (http://sift.jcvi.org/, version 1.0.3)

[4]. The VarScore VAF is provided by Complete Genomics, and reflects the probability that the call is true over the the probability that the call is false, assuming variable allele fractions estimated by a maximum likelihood (expressed in db)

[5]. The somaticScore is provided by Complete Genomics, and reflects the probability that the call is true over the the probability that the call is false, assuming fixed a priori probabilities of somatic mutations (SNP: 1/1Mb, insertion, deletion : 1/10Mb, substitution: 1/20Mb).

[6]. Exact Fisher test the p-values computed from the two alleles readcounts in the tumor and in germline.

[7]. These genomes are germline genomes provided by Complete Genomics.

Table S8 : List of Genes Impacted by a Junction, Related to a Somatic Structural Variant.

[1]. for genes with alternative transcripts, several RefSeq are provided

[2]. "Exon Or Intron Number" : describes the exon / intron identity; for genes with several transcripts, the exon / intron identity for each transcript (listed in the RefSeq column) is provided

[3]. "Distance To Exons" : pairs of distances to exons are provided, measuring the distance to the exon before, and to the exon after the junction. For genes with several transcripts, one pair is provided for each transcript listed in the RefSeq column

[4]. For intragenic structural variants, the second side of the junction is also inside the gene. The detailed position is provided. Of note, for structural variants that are not intragenic, the second side of the structural variant outside of the gene is not specificed

[5]. Identities are provided by Complete Genomics for each junction. For GBP4 and GBP7, the junction Id is the same because the two genes are impacted by a common junction.

[6]. Number of mate pairs that are discordant from the reference genome in terms of alignment, and that were used for calling the junction.

[7]. These genomes are germline genomes provided by Complete Genomics. Many junctions identified as somatic in our project could be found in these genomes, which make them prone to be a false positives. Therefore any somatic junction called in these baseline genomes was discarded.

					Position of the junction					Second side of the junction (for intra-genic structural variants)4

Table S9 : Exome Variants Server (EVS) Allelic Frequencies of the *ARMC5* Variants Identified in the ACTH-Independent Macronodular Adrenal Hyperplasia Patients.

The number of variants and the sequencing coverage were obtained from the Exome Variant Server, NHLBI GO Exome Sequencing Project (ESP), Seattle, WA (URL: http://evs.gs.washington.edu/EVS/) [December 2012 accessed].

[1]. Each frequency is the frequency of the variant over the total number of alleles sequenced. The latter correspond to twice the number of controls sequenced.

Table S10: List of Genes with a HIGH Expression in *ARMC5*-Mutated Compared with *ARMC5* Wild-Type ACTH-Independent Macronodular Adrenal Hyperplasia

[1.] p-values were generated with Limma, and adjusted for multiple testing using the Benjamini- Hochberg correction

[2]. GO stands for Gene Ontology. The significantly enriched Gene Ontologies (GO.1 to GO.20) within the differentially expressed genes are presented, with their annotations and the p-value of their enrichment (generated by DAVID). Whether any of these GO annotations applies to a gene or not, is mentioned for all the genes ("Yes" or "No").

To access the content of the table, please double-clic on the table
