ABSTRACT

Aims: The objectives of this study were to identify clinical predictors of the Traditional Chinese medicine (TCM) clinical index for diabetic peripheral neuropathy (DPN) in type 2 diabetes mellitus (T2DM) patients, develop a clinical prediction model, and construct a nomogram. *Methods:* We collected the TCM clinical index from 3590 T2DM recruited at the Second Affiliated Hospital of Tianjin University of Traditional Chinese Medicine from January 2019 to October 2020. The participants were randomly assigned to either the training group ($n = 3297$) or the validation group ($n = 1426$). TCM symptoms and tongue characteristics were used to assess the risk of developing DPN in T2DM patients. Through 5-fold cross-validation in the training group, the least absolute shrinkage and selection operator (LASSO) regression analysis method was used to optimize variable selection. In addition, using multifactor logistic regression analysis, a predictive model and nomogram were developed. *Results:* A total of eight independent predictors were found to be associated with the DPN in multivariate logistic regression analyses: advanced age of grading (odds ratio/OR 1.575), smoke (OR 2.815), insomnia (OR 0.557), sweating (OR 0.535), loose teeth (OR 1.713), dry skin (OR 1.831), purple tongue (OR 2.278). And dark red tongue (OR 0.139). The model was constructed

using these eight predictor's medium discriminative capabilities. The area under the curve (AUC) of the training set is 0.727, and the AUC of the validation set is 0.744 on the ROC curve. The calibration plot revealed that the model's goodness-of-fit is satisfactory.

Conclusions: We established a TCM prediction model for DPN in patients with T2DM based on the TCM clinical index.

1. Introduction

Diabetes mellitus has been diagnosed in nearly 537 million people worldwide as a result of changes in dietary structure, residents' lifestyles, and economic development. The incidence rate is expected to rise to 11.3% in 2030 and 12.2% in 2045 [[1](#page-10-0)]. From 2013 to 2018, the prevalence of diabetes mellitus in China rose from 10.9% to 12.4% [[2](#page-10-0)]. In 2021, China has the highest percentage of both diagnosed and undiagnosed cases staggering 140.9 and 72.8 million people, respectively.

Although the awareness and treatment rates of diabetes mellitus patients in China have increased in recent years, they are still not optimal. Lifestyle modification is the primary preventive measure for diabetes and its complications [\[3\]](#page-10-0). Diabetic peripheral neuropathy (DPN) is a prevalent and severe chronic complication of diabetes mellitus that affects approximately 30% of patients. It is linked to lower extremity amputations, painful neuropathy symptoms, and an increased risk of death [\[4\]](#page-10-0). Diabetes-related foot ulcers are characterized by foot ulceration or deep tissue destruction caused by DPN [\[5\]](#page-10-0), which affects about 20 million people worldwide each year [\[6\]](#page-10-0). Obesity, hyperglycemia, dyslipidemia, impaired neurotrophic support and insulin signaling, and microvascular diseases all cause downstream oxidative stress, mitochondrial dysfunction, and inflammation, ultimately leading to cellular dysfunction and death [7–[11](#page-10-0)]. The management of diabetic peripheral neuropathy encompasses targeted treatments for neurological symptoms and strategies to prevent DPN's progression and address foot complications [[4](#page-10-0)]. However, the onset of DPN is insidious, and up to fifty percent of patients have no typical conscious symptoms, necessitating that clinicians and patients pay greater attention to early screening for DPN to provide timely and effective diagnosis and treatment [[12\]](#page-10-0).

Nerve conduction studies remain the gold standard for diagnosing and assessing the severity of DPN [[13,14](#page-10-0)]. Before attributing neuropathy to diabetes mellitus, a thorough clinical history and physical examination should be conducted to rule out neuropathy caused by a neurological or orthopedic disease. After the exclusion of lesions, five screening tests (ankle reflex, vibration sensation, pressure sensation, pinprick sensation, and temperature sensation) should be performed for clinical symptoms of neuropathy in diabetes mellitus (including pre-diabetes mellitus), such as pain, numbness, and paresthesia [[4](#page-10-0),[15,16\]](#page-10-0). Generally speaking, these DPN diagnostic strategies are adequate in clinical settings. Neurology consultations and neurophysiological testing are advised when conditions such as atypical symptoms, signs, or diagnostic uncertainty arise [\[13](#page-10-0)]. Academics have investigated and validated early screening, diagnostic methods, and devices for DPN. Several innovative point-of-care devices have the potential to facilitate the early diagnosis of DPN in potentially more treatable conditions [\[17](#page-10-0)]. Still, their accuracy and cost-effectiveness must be studied further [[18\]](#page-10-0). Scored clinical assessments provide a standardized, objective, quantitative, and reproducible method for diagnosis, diagnosing, and grading the severity of DPN [\[15](#page-10-0)]. However, these methods are time-consuming and challenging to implement in clinical settings. Given that DPN is a relatively complex pathological process, it has become imperative to develop a simple, distinct, noninvasive prediction method for early clinical diagnosis with multiple influencing factors to estimate the risk of DPN or the current condition in a busy medical setting.

The primary objective of this research is to develop a scientific prediction model for the risk of DPN occurrence in diabetes mellitus to address the critical need for early screening. TCM diagnosis is based on four processes: sight, hearing, odor, and questioning. The most common method is to check the tongue and pulse. According to research, tongue imaging is linked to type 2 diabetes mellitus (T2DM) and can be used to screen for T2DM [61–[64,](#page-11-0)[68\]](#page-12-0). To our knowledge, no studies have been done to create a clinical prediction model for DPN related to TCM that combines multiple indicators, TCM symptoms, and tongue characteristics.

In this study, a total of 4723 cases of T2DM were included, the potential relationship between DPN and TCM indicators was explored, and a nomogram model was developed to facilitate the early diagnosis of DPN by TCM clinical practitioners.

2. Materials and methods

This study was approved by the institutional ethics committee of Tianjin University of Traditional Chinese Medicine (approval number: TJUTCM-EC20190004), and all participants had to provide informed consent before the study's initiation.

2.1. Study design and participants

Patients with T2DM admitted between January 2019 and October 2020 to the endocrinology department and traditional Chinese medicine surgery department of the Second Affiliated Hospital of Tianjin University of Traditional Chinese Medicine, Tianjin, China, were included in the cross-sectional study. The diagnosis of T2DM was based on a previous diagnosis of fasting plasma glucose (FPG) \geq 7.0 mmol/L or 2 h plasma glucose (PBG) ≥ 11.1 mmol/L at the Second Affiliated Hospital or confirmed diagnosis of DPN based on a positive 128 Hz tuning fork and 10 g monofilaments [[19\]](#page-10-0). The exclusion criteria were as follows [[1](#page-10-0)]: age below 18 [[2](#page-10-0)]; failure to complete the questionnaire [\[3\]](#page-10-0); pregnant or lactating women [[4](#page-10-0)]; unable to cooperate with the complete tongue image collector [\[5\]](#page-10-0); incomplete clinical data. Based on the criteria above, a total of 4723 patients were enrolled in our study. The dataset was randomly divided into two groups: 70% ($n = 3297$) comprised the training group, and 30% ($n = 1426$) formed the validation group. The training group was used to construct the model, while the validation group was used to evaluate the model's capabilities.

2.2. Baseline data collection and processing

Each participant's age and gender were adequately recorded. During the study, patients who smoked at least one cigarette per day were considered smokers. The BMI was calculated by dividing weight in kilograms by height in meters squared. The Chinese guidelines for the prevention and control of overweight and obesity in adults classify BMI into: *<*18.5, 18.5–23.9, 24–28, and *>*28 kg/m2 [[20\]](#page-10-0).

2.3. Clinical symptoms of TCM collection

Using a standardized questionnaire (Information Record Form of TCM Clinical Four Diagnostics) developed by Shanghai University of Traditional Chinese Medicine, trained researchers from the School of Health Sciences and Engineering at Tianjin University of Traditional Chinese Medicine interviewed each patient and collected clinical symptom information. "Yes" responses were given 1 point, and "No" responses, 0 [[21\]](#page-10-0).

2.4. Collection of tongue features

Two researchers identified tongue characteristics and recorded the findings in the questionnaires. The Tongue Diagnosis Analysis-1 (TFDA-1) instrument developed by the national key research and development plan was used to collect tongue images [\[22](#page-10-0)]. Two experienced TCM experts were asked to review the images simultaneously; in the event of a disagreement, a third expert would decide the outcome.

2.5. Statistical analysis

The statistical analysis was performed using SPSS (26.0) and STATA (version 15.0). As appropriate, Chi-squared tests were used to compare the training and validation groups. All reported levels of statistical significance were two-sided, with a significance level of 0.05. Different variables were evaluated, and the odds ratio and 95% confidence interval (CI) were calculated using the logistic regression analysis method. Next, variables with a P value of less than 0.05 were added to the model. Statistical significant variables were included in the multivariate logistic regression analysis (backward: conditional). This study used the minimum absolute contraction and lasso regression to select the most valuable predictor candidates [[23\]](#page-10-0). The LASSO regression analysis performed a 5-fold cross-validation for centralization and normalization of the included variables before choosing the optimal lambda value [[24\]](#page-11-0). Finally, a nomogram model was developed to identify T2DM patients at risk for DPN.

2.6. Model evaluation

The prediction model's efficacy evaluation focuses primarily on discrimination ability (discrimination), accuracy (calibration curve), and clinical applicability. The closer the AUC value is to 1, the better the prediction model is [\[25](#page-11-0)]. The calibration degree is an essential metric for assessing the precision of a disease risk model. Finally, a decision curve analysis was performed to evaluate the clinical efficacy of the model [\[26](#page-11-0)]. Fig. 1 depicts a Figdraw ([www.figdraw.com\)](http://www.figdraw.com) flowchart of this study. LASSO regression, multivariate logistic analysis, and the establishment of a nomogram model were performed using STATA (version 15.0).

3. Results

3.1. Patient characteristics

We analyzed three clinical variables: demographic characteristics, symptoms and signs of TCM, and tongue features collected via a

Fig. 1. The flowchart of the TCM prediction model for DPN in T2DM patients based on the TCM clinical index.

standardized questionnaire with categorical variables between 2019 and 2021 [[21\]](#page-10-0). The study included 4430 T2DM patients and 293 DPN patients. Finally, 4723 patients were divided into the training group (3297 individuals) and the validation group (1426 individuals) in this study. Based on the standard of ten events per candidate predictor parameter, this study's 25 predictors required at least 250 individuals with their respective events [[27\]](#page-11-0). In addition, considering other sample size requirements for developing a clinical prediction model, the training group sample size of 3297 patients met the standard optimal sample size for further statistical analyses. This study included 1541 males and 1756 females, the majority aged 60–89 (61%). 45.7% of the patients were overweight (Table 1). The DPN group had more frequencies of age *>*60 years old than the T2DM group. The most frequent BMI interval in DPN patients was 24.6–28 (42.3%). The DPN group has more male members (57.3%) than female members (42.7%). Significantly more individuals in the DPN group (44.4%) were smokers than in the T2DM group (21.9%), and the frequency of purple tongue and the yellow coating was significantly higher in the DPN group than in the T2DM group (S1). [Fig. 6](#page-7-0) displays the tongue characteristics, the left column is the color of the tongue [\(Fig. 6a](#page-7-0)), the middle column is the tongue shape [\(Fig. 6](#page-7-0)b), and the right column is the color and shape of the coating ([Fig. 6c](#page-7-0)).

3.2. Factor selection

In the training group, univariate analysis was used to identify risk factors associated with DPN in patients with T2DM. Significantly different predictors included age (OR 1.440, 95% CI 1.140–1.820, $p = 0.002$), sex (OR 0.558, 95% CI 0.416–10.747, $p = 0.000$), smoking (OR 2.763, 95% CI 2.061–3.705, p = 0.000), insomnia (OR 0.565, 95% CI 0.417–0.766, p = 0.000), sweating (OR 0.530, 95% CI 0.362–0.776, $p = 0.001$), loose teeth (OR 1.721, 95% CI 1.277–2.319, $p = 0.000$), dry skin (OR 1.958, 95% CI 1.412–2.716, $p =$ 0.000), purple tongue (OR 2.709, 95% CI 1.827–4.017, $p = 0.000$), dark red tongue (OR 0.115, 95% CI 0.037–0.361, $p = 0.000$), yellow coating (OR 1.375, 95% CI 1.011–1.869, $p = 0.042$), and greasy coating (OR 0.639, 95% CI 0.441–0.925, $p = 0.018$). Other predictors were not significantly different ([Table 2](#page-8-0)).

Through the shrinkage estimation method, the LASSO method can also select relevant features in high-dimensional data. In this

Table 1

Clinical characteristics of the study participants.

Indicators	Clinical characteristics N (%)	Training group (3297)	Validation group (1426)	P value
Baseline Data	Age			0.533

	Thick coating	778 (23.6)	317 (22.2)	0.307
	Greasy coating	832 (25.2)	368 (25.8)	0.679

Note: Values are shown with numbers and proportions. P *<* 0.05 means a significant difference. BMI, Body mass index, Underweight *<*18.5 kg/m2, normal BMI range 18.5–23.9 kg/m2, overweight 24.0 ≤ BMI *<*28.0 kg/m2; obesity *>*28.0 kg/m2.

Fig. 3. Nomogram prediction model of DPN. Risk factors of age, smoke, insomnia, sweating, loose teeth dry skin, purple tongue, dark red tongue for nomogram prediction model. It was established by the training group. A total point was calculated by combining appearance of smoke, loose teeth, dry skin, purple tongue and age grade. (For interpretation of the references to color in this figure legend, the reader is referred to the Web version of this article.)

study, the training group was subjected to LASSO regression. The modification of the penalty coefficient λ gradually reduced the number of model variables. A 5-fold cross-validation error was selected as the minimum $\lambda+1$ (lambda. 1se = 3.262) as the optimal value of the model (Fig. 2a–b), which included 8 of the 25 variables. Then, the eight variables obtained from the Lasso regression, including age, smoke, insomnia, sweating, loose teeth, dry skin, purple tongue, and dark red tongue were significantly different

Fig. 4. Receiver operating characteristic curve (ROC) validation of the DPN risk nomogram prediction. The x-axis represents the false positive rate of the prediction. The y-axis represents the true positive rate of the prediction, the red line represents the performance of the model of training set (a) and validation set (b). Calibration curves of the predictive DPN nomogram prediction model. The x-axis represents the predicted risk of DPN. The y-axis represents actual diagnosed cases of DPN, the red line represents a perfect prediction by an ideal model, the blue circle represents the performance of the training set (c) and validation set (d), the results illuminate the agreement between the predicted risks of DPN and the observed incidence of DPN. (For interpretation of the references to color in this figure legend, the reader is referred to the Web version of this article.)

between the two groups. Similarly, 11 predictors were derived from univariate analysis, and a 5-fold cross-validation yielded the same result. In light of this, the logistic multiple regression model incorporated a model with eight independent predictors.

3.3. Model development

A logistic multiple regression analysis was conducted on the identified potential DPN predictors (p *<* 0.05). The predictors included in the prediction model were age (OR 1.575, 95% CI 1.236–2.006, p = 0.000), smoking (OR 2.815, 95% CI 2.079–3.811, p = 0.000), insomnia (OR 0.557, 95% CI 0.408–0.761, $p = 0.000$), sweating (OR 0.535, 95% CI 0.362–0.791, $p = 0.002$), loose teeth (OR 1.713, 95% CI 1.258–2.331, p = 0.001), dry skin (OR 1.831, 95% CI 1.303–2.574, p = 0.000), purple tongue (OR 2.278, 95% CI 1.514–3.428, $p = 0.000$), and dark red tongue (OR 0.139, 95% CI 0.044–0.441, $p = 0.001$) [\(Table 3](#page-8-0)). A DPN risk nomogram was also constructed based on our model [\(Fig. 3](#page-4-0)).

3.4. Model validation

The ROC curve was used to evaluate the predictive model's discriminatory ability. During internal validation, the predictive nomogram in the training group demonstrated good discrimination (AUC = 0.727) (Fig. 4a). The curve indicated that the prediction nomogram had a good fit (AUC = 0.744) (Fig. 4b). In addition, the calibration curve showed that the predicted DPN incidence was consistent with the observed incidence in the training and validation groups (Fig. 4c–d).

Fig. 5. Decision curve analysis (DCA) was exhibited to estimate the clinical usefulness of DPN nomogram prediction model. The x-axis represents the threshold probabilities, the y-axis represents the standardized net benefit in DCA curves, and the black dotted line represents DPN nomogram, the solid black line represents the condition that all patients have DPN, and the gray line represents the condition that none have DPN. (a) From the training group, (b) from the validation group.

3.5. Decision curve analysis

The decision curve analysis (DCA) was presented to assess our model's clinical utility. The DCA curves demonstrated that along with an increase in the probability threshold, referring to our predicted models when deciding whether to intervene can add net benefit compared to intervening in all patients or none (Fig. 5a–b).

4. Discussion

The prevalence of DPN among Chinese patients diagnosed with T2DM was greater than 50% [[28,29\]](#page-11-0). DPN is characterized by a high incidence, an insidious onset, atypical clinical symptoms, and significant harm, all of which harm patients' quality of life. Since DPN is difficult to diagnose due to its unclear pathogenesis, early risk assessment, and prevention research is critical.

. In this study, T2DM patients were examined to determine the risk factors for DPN lesions and to develop a DPN nomogram risk prediction model that included eight variables: age, smoking, insomnia, sweating, loose teeth, dry skin, purple tongue, and dark red tongue. In addition, the ROC curve and DCA demonstrated that the model possesses excellent discriminatory and predictive abilities. This nomogram is a noninvasive, easy-to-use, and effective tool that could be used in the outpatient setting to perform a rapid assessment of DPN risk in patients diagnosed with T2DM, particularly in TCM clinics. It is a cross-sectional study of T2DM patients in the Tianjin region in which the patients' characteristics (demographic characteristics, tongue features, and symptoms) were systematically recorded and collected. Using the 5-fold cross-validation LASSO regression method, the 27 variables were initially reduced to 8 potential predictors. Then, we obtained 11 predictors from univariate analysis, ran 5-fold cross-validation LASSO regression, and obtained the same result.

According to previous research, the primary risk factors for DPN are diabetes duration, hyperglycemia, age, pre-diabetes, hypertension, hyperlipidemia, and smoking [\[30](#page-11-0)]. The 2020 Guidelines for the Prevention and Treatment of T2DM in China also note that patients with diabetes older than ten years are more likely to develop obvious DPN. A cross-sectional multicenter study in India revealed that the severity of DPN was significantly related to age and duration of diabetes [\[31](#page-11-0)]; the risk of DPN increased by 7% for each additional year of diabetes duration [[32](#page-11-0)]. Age and abnormal glucose and lipid metabolism harm the vascular endothelium, disrupt the homeostasis of oxidative stress in the body, affect nutrient supply, and damage nerve cells [\[33](#page-11-0)]. A 9-year follow-up study involving 512,891 urban and rural adults in China revealed that long-term smokers had a 15–30% greater risk of developing diabetes than nonsmokers. Among urban men, the hazard ratio was greater the younger they started smoking and the more they smoked [[34\]](#page-11-0). A meta-analysis of 84 prospective studies, including nearly 300,000 diabetes cases, found that active smoking was associated with an overall hazard ratio for reported diabetes of 1.37 (95% prediction interval 1.11–1.50) [[35\]](#page-11-0). DPN is more prevalent in diabetic patients who smoke, are older than 40, and have inadequate blood glucose control. A recent study revealed that smoking is an independent risk factor for DPN and that the risk of DPN increases with the duration of smoking and the level of addiction. Notably, heavy smokers had poorer nerve conduction, which may be due to smoking-induced inflammatory cytokine release and impaired endothelial cell function [\[9\]](#page-10-0). Smoking is also significantly associated with the risk of diabetic foot, as the daily tissue hypoxia caused by smoking can result in vascular and neuropathy in diabetic patients' extremities [[36\]](#page-11-0).

Patients with DPN can effectively avoid infection and reduce the incidence of diabetic foot by protecting their skin. However, DPN can cause damage to the sensory nerves, resulting in hypoesthesia and diminished temperature sensation, leading to insensitivity to external stimuli and skin fragility [\[37](#page-11-0)]. When the motor nerve is damaged, toe deformity and changes in gait can occur, resulting in abnormal local and plantar pressure loads that cause calluses and ulcers [\[38](#page-11-0)]. In addition, DPN-induced impairment of sweat nerve

Fig. 6. Tongue features Inside the red dotted box is the purple tongue, the left column is the color of the tongue, including Purple tongue, Crimson tongue, Dark red tongue (a); The middle column is the shape of the tongue, including Spotted tongue, Fissured tongue, Teeth marked tongue and Enlarged tongue (b); The column on the right is the color and shape of the coat, including Yellow coating, Less coating, Thick coating, Less coating (c). (For interpretation of the references to color in this figure legend, the reader is referred to the Web version of this article.)

function can cause atrophy of sweat glands, a weakened perspiration response, and dry skin, resulting in pruritus, chapped skin, and foot skin ulcers [[39\]](#page-11-0). According to a study of 142 people with diabetes, impaired sweat secretion may eventually weaken the skin barrier and increase the risk of foot ulcers [\[40\]](#page-11-0). DPN patients with abnormal sweating function have a 15-fold increased risk of foot ulcers [[41\]](#page-11-0). The visual indicator plaster method has a high sensitivity and low negative predictive value for the diagnosis of DPN and is simple to perform for the assessment of foot skin dryness [\[42](#page-11-0)]. The Sudoscan technology evaluates the degree of neurological impairment of sweat glands by detecting changes in chloride ion concentration in the palm and sole sweat to provide a quantitative analysis of sweating function [\[43](#page-11-0)].

Most diabetic patients exhibit oral symptoms, including periodontal disease, tooth loss, dental caries, dry mouth, delayed wound healing, and taste dysfunction [[44\]](#page-11-0). It is widely recognized that periodontitis and diabetes interact in both directions [[45\]](#page-11-0). Periodontitis is a chronic, long-lasting inflammation frequently accompanied by gum infection, periodontal redness, bleeding gums, loose teeth, tooth sensitivity, and persistent bad breath [\[46](#page-11-0)]. Periodontitis causes immune impairment and systemic inflammation, which can result in dysregulation of bacterial flora, decreased function of islet cells, insulin resistance, impaired fasting blood glucose, and endothelial dysfunction, thus interfering with normal glucose metabolism [47–[50\]](#page-11-0). In patients with diabetes mellitus, the prevalence of severe periodontitis increases three-to fourfold, and the severity is associated with inadequate glycemic control [[51\]](#page-11-0). Numerous epidemiological studies, clinical intervention studies, and animal experiments have supported the hypothesis that periodontitis may be

Table 2

Risk factors for DPN in T2DM patients according to the logistic regression model.

Table 3

Multivariate logistic analysis of risk factors to DPN.

Features	OR	Lower	Upper	P value
age	1.575	1.236	2.006	0.000
smoke	2.815	2.079	3.811	0.000
insomnia	0.557	0.408	0.761	0.000
sweating	0.535	0.362	0.791	0.002
loose teeth	1.713	1.258	2.331	0.001
dry skin	1.831	1.303	2.574	0.000
purple tongue	2.278	1.514	3.428	0.000
dark red tongue	0.139	0.044	0.441	0.001

an independent risk factor for diabetes mellitus, resulting in a poor diabetes prognosis [\[52](#page-11-0)–54]. In the interim, the incidence of diabetes in patients with severe periodontitis increased by 53% [\[52](#page-11-0)]. In generally healthy individuals, periodontitis can significantly increase the risk of developing diabetes, with adverse effects on glycemic control, diabetic complications, and the development of TD2M [[55\]](#page-11-0). Periodontal disease and increased missing teeth may be risk factors for developing new-onset diabetes [[56\]](#page-11-0). In adults with diabetes mellitus, the likelihood of tooth loss was double that of adults without tooth loss [\[57](#page-11-0)]. Therefore, adults with diabetes mellitus must be encouraged to maintain good oral hygiene and teeth [[58\]](#page-11-0).

According to the color, texture, shape, and fur characteristics of the panoramic tongue image, a proposed TCM-based diabetes diagnosis method has good classification performance in the early stage of the disease. Therefore, it can be used as a preliminary screening procedure for the future early detection of T2DM and its complications [[59\]](#page-11-0). Doctors have traditionally examined these tongue characteristics based on years of subjective experience to aid treatment selection and prognosis [\[60,61](#page-11-0)]. Studies have correlated a yellow tongue coating with an increased risk of diabetes [[62,](#page-11-0)[63\]](#page-12-0). Through traditional machine learning and deep learning algorithms, a standardized, objectified, and quantified tongue image diagnosis method and an automatic tongue diagnosis system have been established and developed, with improved prediction accuracy and the ability to increase the consistency of subjective diabetes diagnosis [\[22,](#page-10-0)[64,65\]](#page-12-0). Some TCM indexes (tongue features and symptoms), such as chest tightness, spontaneous perspiration, a wiry pulse, and greasy tongue coating, can also improve the diagnosis of metabolic syndrome, according to Xia et al. who compared three classic machine learning methods [\[66](#page-12-0)]. Japanese non-smoking men and women with a yellow tongue coating had a higher prevalence of diabetes mellitus, according to a previous epidemiological study [[62\]](#page-11-0). Blood stasis is regarded as one of the primary accompanying syndromes of DPN in TCM. Li et al. discovered that 89–96% of patients with DPN have blood stasis [\[67](#page-12-0)]. Moreover, Morita A. et al. Demonstrated an objective evaluation of the relationship between blood stasis and patients with a dark purple tongue [\[65](#page-12-0)]. The performance of the tongue is essential for detecting blood stasis. A study indicated that patients with T2DM have increased blood stasis tongue manifestations, which are correlated with severe arterial stiffness [\[68](#page-12-0)]. Meanwhile, this is the first study to identify the purple tongue as an independent risk factor positively associated with DPN.

4.1. Limitations

First, the populations were recruited from a single center, so whether these results apply to other regions is still being determined. Because tongue characteristics vary regionally in DPN, we will evaluate some of these indicators in future research to supplement the existing models. Second, we constructed our model based on demographic characteristics. TCM symptoms and tongue features were assessed using an anthropometric questionnaire, but other variables such as biochemical parameters were not included in the evaluation. Third, despite the lack of evidence, other TCM symptoms and tongue characteristics don't include as variables in our study may be associated with the occurrence and development of DPN risk in T2DM.

5. Conclusion

The eight variables about DPN confirmed in his analysis, including age, smoking, insomnia, sweating, loose teeth, dry skin, purple tongue, and dark red tongue, have great clinical application value for identifying DPN risk in T2DM, particularly for TCM clinical doctors. In addition, it can assist clinical personnel in providing a reference for screening and early diagnosis of DPN by incorporating TCM patient symptoms and tongue characteristics into the risk prediction model and calculating the risk score to assess the risk of DPN in T2DM patients.

Author contributions

1) conceived and designed the experiments by ZT, YF and HW; 2) performed the experiments by ZT, XS, DW, JG, YG, YZ, HB and ZZ; 3) analyzed and interpreted the data by ZT, XS, and ZW; 4) contributed reagents, materials, analysis tools or data by ZT, YF, HW and ZW; 5) wrote the paper by ZT, YF, HW.

Funding

This project was supported by the National Key Research and Development Program of China (approval No.: 2017YFC1703305) and Hebei Administration of Traditional Chinese Medicine 2022 Scientific Research Program of Traditional Chinese Medicine (approval No.: 2022554) during the 13th 5-year plan period.
