36 **Abstract**

37 Metabotropic glutamate receptors belong to a family of G protein-coupled receptors that are

38 obligate dimers and possess a large extracellular ligand-binding domain (ECD) that is linked

39 via a cysteine-rich domain (CRDs) to their 7-transmembrane (TM) domain. Upon activation,

40 these receptors undergo a large conformational change to transmit the ligand binding signal

41 from the ECD to the G protein-coupling TM. In this manuscript, we propose a model for a

42 sequential, multistep activation mechanism of metabotropic glutamate receptor subtype 5. We

43 present a series of structures in lipid nanodiscs, from inactive to fully active, including agonist-

44 bound intermediate states. Further, using bulk and single-molecule fluorescence imaging we

45 reveal distinct receptor conformations upon allosteric modulator and G protein binding.

Introduction

63

64 Metabotropic glutamate receptors (mGlus) belong to a family of obligate dimeric G protein-
65 coupled receptors (GPCRs), that are activated by the excitatory neurotransmitter, *L*-glutamate[1].
66 Each protomer contains a large ECD that is made up of a Venus fly trap (VFT) domain, that
67 contains the orthosteric ligand binding site, and a cysteine-rich domain (CRD). The CRD
68 connects the VFT to the family-defining 7-transmembrane (TM) domain (Extended Data
69 Figure 1a)[1]. The binding of glutamate causes the closure of the VFTs and a protomer
70 rearrangement that brings the CRDs and TM domains in close proximity[2]. Dimerization of the
71 mGlus is mandatory for their function, and the rearrangement upon activation of the receptors
72 is a complex allosteric process with the two protomers influencing each other[3]. Allosteric
73 modulators of mGlus bind the TM domain[4] to regulate signaling by themselves or in
74 conjunction with orthosteric ligands. Ultimately, agonists and positive allosteric modulators
75 (PAMs) activate mGlus by stabilizing intermolecular interactions between the protomers
76 which enable G protein coupling to the TM domain.

77 To better understand the activation mechanism of mGlus, and to delineate the allosteric link
78 between ligands and G proteins, we took mGlu5 as a representative of the mGlu family and
79 employed a combination of structural and biophysical techniques to characterize the
80 conformational landscape of receptor activation. We first show the importance of a lipid bilayer
81 for mGlu5 activation. To comprehensively understand the receptor activation pathway, we
82 determine structures of mGlu5 in the presence of a small molecule orthosteric agonist and an
83 allosteric modulator, as well as the allosteric nanobody, Nb43[2]. As a pure PAM, Nb43
84 potentiates the activity of orthosteric agonists but lacks intrinsic activity of its own. In the
85 presence of the orthosteric agonist L-quisqualic acid (Quis) and Nb43, we resolved two
86 receptor conformations; (i) an intermediate (Intermediate 1a, Figure 1a) with the VFT upper
87 lobes closed but a large interprotomer distance reflecting an inactive conformation, and (ii) an
88 "active-like" structure (Intermediate 2a, Figure 1a) where the VFT lower lobes, CRDs and the
89 TMs are in close proximity. It should be noted that for the purpose of discussion, all
90 conformations between Apo and G protein-bound "Fully Active", are named "Intermediates".
91 Addition of agonist-PAM 3-cyano-*N*-1,3-diphenyl-1*H*-pyrazol-5-yl)benzamide (CDPPB) to
92 the Quis- and Nb43-bound mGlu5 fully stabilized a single active conformation (Intermediate
93 3a, Figure 1a) that resembles the Quis and Nb43-bound Intermediate 2a structure. Interestingly,
94 in this complex, we observe an asymmetric action of CDPPB, with density supporting its
95 binding to only one of the two TMs, as opposed to a structure of mGlu5 with CDPPB alone,

3

96   but *without* Quis or Nb43, where we observe CDPPB in both TMs (Intermediate 1b, Figure

97   1a). We further investigate the intersubunit conformational changes upon ligand and G protein

98   binding using bulk fluorescence spectroscopy and single-molecule Förster resonance energy

99   transfer (smFRET). We observe receptor conformations that correlate well with the determined

100   structures as well as several receptor conformations that are uniquely observed in biophysical

101   studies, including states stabilized by CDPPB (Intermediates 2band 3b, Figure 1a) and one

102   stabilized by G protein (fully active). Finally, combining all the data we propose a model for

103   the step-wise activation of mGlu5. Figure 1a gives an overview of the model developed from

104   the results presented in this manuscript.

105   **Results**

106   **A lipid environment is critical for mGlu5 activation**

107   To identify the best conditions for studying mGlu5 activation, we monitored the ability of

108   mGlu5 to drive GTP turnover via the heterotrimeric G protein G_q in detergent micelles and

109   reconstituted in lipid nanodiscs using the belt protein MSP2N2 (~ 16 nm diameter)[5] and a

110   POPC/POPG lipid mixture (Extended Data Figure 1b). In detergent micelles, we observed no

111   activation of G_q by mGlu5 bound to Quis, and only minimal activation (~ 20 % above G_q alone)

112   by mGlu5 bound to both Quis and CDPPB (Extended Data Figure 1c), while the M1 muscarinic

113   receptor in detergent micelles was able to efficiently activate G_q (Extended Data Figure 1d). In

114   contrast, mGlu5 in lipid nanodiscs was able to robustly activate G_q by Quis alone or Quis and

115   CDPPB (Extended Data Figure 1c). To assess whether this dependence on lipid environment

116   for mGlu5 activation is a consequence of alteration in receptor conformation, rather than a

117   direct effect of lipid on either G_q activation or mGlu5 affinity for ligand, we performed

118   hydrogen-deuterium exchange monitored by mass spectrometry (HDX-MS). Upon agonist

119   binding to mGlu5 in detergent, we observe changes in the VFT, consistent with ligand binding[2]

120   (Extended Data Figure 1e). These VFT changes in detergent are nearly identical to HDX-MS

121   curves of agonist-bound mGlu5 in nanodiscs (Extended Data Figure 1e-f). Thus, the effects of

122   agonist binding on the VFT do not appear to depend on the receptor TM environment.

123   However, there are notable differences in the TM region of agonist-bound mGlu5 between

124   detergent and nanodiscs: specifically, peptides in the intracellular region of TM3 exhibit

125   reduced deuterium uptake in mGlu5 in nanodiscs compared to mGlu5 in detergents (Extended

126   Data Figure 1e, g). Other peptides in the TM region, including in TM5, do not exhibit

127   differences in deuterium uptake, suggesting that the detergent environment does not globally

128   destabilize the receptor (Extended Data Figure 1g). In other mGlus, e.g. in mGlu2, this region

4

129   of TM3 undergoes conformational changes upon activation and interacts with G protein[6]

130   (Extended Data Figure 1h). Taken together, these data are consistent with a model where lipids

131   modulate the ability of mGlu5 to adopt an active state capable of GTP turnover.

Quis-bound mGlu5 exists in two conformation

133   To better understand the activation mechanism of mGlu5, we determined the structure of Quis

134   and Nb43 bound mGlu5 reconstituted into lipid nanodisc using single particle cryo-electron

135   microscopy (cryo-EM). Data processing revealed two distinct conformations of the receptor

136   (Extended Data Figure 2). Though both structures have Quis bound (to both protomers), one

137   shows an "intermediate" conformation (Intermediate 1a, Figure 1a) wherein the VFTs are

138   closed, but CRDs and TMs are far apart as in the inactive mGlu5 structure (Figures 1b,

139   Extended Figure 3a), while the other conformation is "active-like" (Intermediate 2a, Figure 1a)

140   such that the CRDs and TMs are close together forming the TM6-TM6 interface, the hallmark

141   of Family C activation[2] (Figure 1c).

142   To investigate changes accompanying Quis binding, we compared the previously determined

143   Apo (PDB code: 6N52[2]) structure to the current Quis-bound, Intermediate 1a structure

144   (Extended Data Figure 3a). Upon Quis binding, there is a decrease in distance between the

145   upper and lower lobes of the VFT (Figure 2a). This decrease is mostly due to the closure of the

146   upper lobe (Figure 2a, Extended Data Figure 3b). The upper lobe closure is accompanied by

147   some rearrangements in the lower lobe and the "hinge region" (the region between the lobes in

148   the dimer interface (Extended Data Figure 1a, Extended Data Figure 3b). For example, changes

149   to Quis interacting residues such as W100 and E279 (Figure 2b, Extended Data Figure 3a)

150   result in conformational changes in the B and C helices at the intersubunit interface (Figure 2a-

151   b). Hindrance to the movement of these residues appears to stabilize the receptor in an inactive

152   conformation, as seen in the antagonist-bound structure (PDB code: 7FD9[7]) (Extended Data

153   Figure 3c). Hence, changes in the lower lobe residues (e.g. E279) and the "hinge region"

154   triggers rearrangement of the upper lobes (i.e. closing) upon Quis binding (Figure 2a, Extended

155   Data Figure 3b).

156   To study the structural changes that occur subsequent to Quis binding to form the active state

157   of the receptor, we compared the Quis-bound Intermediate 1a (Figure 1a) and the Quis-bound

158   Intermediate 2a (Figure 1a) structures of mGlu5 (Figure 2b-c). We observe a large "twisting"

159   of the VFT lower lobe in the Intermediate 2a structure(Figure 2c, Extended Data Figure 4a).

160   The lower lobe of the VFT moves as a rigid body and maintains the Quis binding pocket

5

161   (RMSD ~ 0.5, Extended Data Figure 4b) and initiates the rearrangement of the B and C helices

162   in the hinge region (Figure 2b, c). These structural changes ultimately lead to the CRDs and

163   TMs (Extended Data Figure 5) moving close to each other (hallmark of Family C GPCR

164   activation) to activate mGlu5.

Symmetric to asymmetric binding of mGlu5 PAM

165

166   Allosteric modulators of Family C GPCRs bind in the TM region and modulate orthosteric

167   ligand binding and signaling. Crystal structures of single mGlu TM domain bound to negative

168   allosteric modulators (NAMs) have been previously determined[8-10]. To gain structural insights

169   into the activity of allosteric modulators in the context of the full-length receptor, we

170   determined the structures of nanodisc incorporated CDPPB-bound mGlu5 (and Nb43) in the

171   absence and presence of Quis (Figure 3a, Extended Data Figure 6-7). In the absence of Quis,

172   CDPPB-bound mGlu5 (Intermediate 1b, Figure 1a) adopts a conformation in which the

173   protomers are separated and we observe density for CDPPB in both TM protomers indicating

174   *symmetric* binding (similar to previously seen for mGlu bound to NAM [11,12]) (Extended Data

175   Figure 8). However, in the presence of Quis, CDPPB binds to the TM of only one protomer

176   (i.e. is bound *asymmetrically*) (Figure 3a). Moreover, unlike Quis alone, in Quis and CDPPB

177   we obtained only one conformation with the protomers together (Intermediate 3a, Figure 1a,

178   Extended Data Figure 6), consistent with stabilization of the active conformation (Extended

179   Data Figure 9a-b).

180   Asymmetric allosteric modulator binding to only one protomer TM is seen in other Family C

181   GPCRs[6]. CDPPB interacts similarly to the mGlu5 NAM, MPEP (PDB code: 6FFI[10]); with the

182   exception of a large outward motion of W785[6.50] (Figure 3b, Extended Data Figure 9c)

183   (superscript indicating GPRDB canonical numbering scheme[13]). In the CDPPB-bound

184   protomer, the entire TM6 is moved outward (C785[6.64] Cα-Cα ~ 3.5 Å), with Y779[6.44] pointing

185   towards the protomer that does not contain CDBBP (Figure 3c, Extended Data Figure 9d-e).

186   This appears to result in the inward movement of TM6 in the CDBBP-less protomer, with

187   W785[6.50] occluding the PAM binding site (Extended Data Figure 9f). This asymmetric PAM

188   binding allows the protomer TMs to form a tight interface.

189   To tease out the differences between the Quis-bound Intermediate 2a and CDPPB, Quis-bound

190   Intermediate 3a states, we carried out three-dimensional variability analysis (3DVA)[14]. In both

191   cases, we observed similar modes of variability (SI Video 1), suggesting these are of biological

192   relevance, rather than being artifacts resulting from overfitted noise in cryo-EM data. Notably,

193   in the Quis-bound dataset, we detect a more pronounced "stretch" motion between VFT and

194   TM domains (SI Video 1). Given that CDPPB binds the TM domain, we hypothesize that

195   CDPPB can "lock" the TM-TM interface of mGlu5 homodimer in an active conformation,

196   consistent with the role of CDPPB as a PAM. In addition, 3D flexible refinement (3Dflex)[15]

197   revealed an asymmetric stretching pattern (SI Video 2), wherein one protomer exhibited greater

198   translational movement than the other. This indicates some asymmetry in the activation of the

199   protomers in the presence of CDPPB, perhaps consistent with the observed asymmetric PAM

200   binding (Figure 3a).

Effect of ligand binding on ICL2 conformation

202   Previous structural studies of mGlu receptors have shown that ICL2 is stabilized in the presence

203   of G protein[6,16]. To investigate conformational changes in ICL2 following ligand binding, we

204   used the environmentally sensitive fluorophore, monobromobimane (bimane) as a

205   conformational reporter (Extended Data Figure 10a-c). We performed bimane spectroscopy on

206   two versions of nanodisc-incorporated mGlu5, the WT, with two native cysteines, C681[ICL2]

207   and C691[4.30], labeled (Figure 3d, Extended Data Figure 10d) and mutant mGlu5 with only

208   C681[ICL2] labeled (Extended Data Figure 10e, f). Notably, the two bimane-labeled constructs

209   yielded similar results (Extended Data Figure 10d, f). The addition of Quis alone did not

210   produce a significant change (Figure 3d, Extended Data Figure 10d) in the bimane fluorescence

211   spectrum, suggesting that an orthosteric agonist alone has a limited ability to stabilize an active

212   conformation of TM intracellular loops. However, the addition of CDPPB to apo- or Quis-

213   bound mGlu5 increased fluorescence, indicating a change in the ICL2 environment (Figure 3d,

214   Extended Data Figure 10d-f). Interestingly, compared to Quis-alone, the structure of mGlu5

215   with Quis and CDPPB-bound, shows some changes in TM3 and TM4. These changes could

216   be potentially contributing to changes in ICL2 (Extended Data Figure 10g). No further change

217   was observed with the addition of G_q (Figure 3d). On the other hand, the mGlu5 NAM MTEP

218   (with Quis or antagonist, LY341495) binding dramatically decreased fluorescent intensity

219   (Figure 3d, Extended Data Figure 10d-f). The decrease in fluorescence with the NAM could

220   be due to bimane quenching by adjacent aromatic residues[17], such as, for example when ICL2

221   residue Y757[5.57] approaches the TM domain in the active conformation. This contrasts with the

222   increase in fluorescent intensity in the presence of the PAM, CDPPB, when ICL2 may adopt

223   an extended conformation (ICL2 in Intermediate 1b, 2b and 3a, 3b in Figure 1a). Hence,

224   allosteric modulators appear to regulate ICL2 conformation.

225

Activation dynamics of mGlu5

Agonist binding to the VFT triggers TM rearrangements via the CRD. To investigate the mechanism of mGlu5 activation, we studied the conformational dynamics of the CRDs using single-molecule fluorescence resonance energy transfer (smFRET)[18,19]. smFRET has been used to study the VFT conformational changes upon glutamate binding[20]. We site-specifically labeled a single introduced Cys (in a minimal Cys background (Extended Data Figure 10a-c)) in the CRD of each protomer at position 560, with cysteine-reactive versions of LD555 (donor) and LD655 (acceptor), to probe the distance between the CRDs as a measure of mGlu5 activation (Figure 4a, Extended Data Figure 11a).

In the Apo state, mGlu5 exhibits a dominant peak centered at a FRET efficiency of ~ 0.25 and includes a broad right skew to higher FRET values (Figure 4b, d, grey, Extended Data Figure 11b). This low-FRET state at ~ 0.25 is increased by the orthosteric antagonist LY341495, indicating that it corresponds to the inactive state (Extended Data Figure 11c). Upon Quis binding, there is a shift in the occupancy to a mid-FRET state, centered at a peak of ~ 0.6 FRET (Figure 4b, d, cyan). Based on the distance between residue 560 in each protomer in the different structures that we obtained, the low and mid-FRET populations appear to correspond to the two distinct Quis-bound structures seen above (Figure 1a): the Intermediate 1a state (low-FRET) and the Intermediate 2a state (mid-FRET) (Extended Data Figure 11a). mGlu5 incubated with CDPPB alone occupies a dominant peak at ~ 0.25 (Intermediate 1b, Figure 1a) and a peak at ~ 0.6 (Intermediate 2b, Figure 1a) (Extended Data Figure 11d). Intermediate 2b was not detected by cryoEM. In the presence of Quis and CDPPB, the ~ 0.6 peak is dominant (Intermediate 3a, Figure 1a), with a decrease in the low-FRET state (Figure 4b, d dark green) and an emergence of a high-FRET peak at ~ 0.75 (Figure 4b, d dark green). This ~ 0.75 peak corresponds to a distinct active-like state of the receptor (Intermediate 3b, Figure 1a), not seen in the cryoEM structures. However, our 3Dflex analysis of the Quis and CDPPB cryoEM dataset, reveals conformations where the CRDs of the homodimers are closer ("squeeze" motion) than that seen in the Quis structure (Extended Data Figure 11e, SI Video 2), agreeing with Intermediate 3b. These observations indicate that the CRDs are dynamic, that agonist and PAM binding progressively increases the occupancy of states in which the CRDs come into closer, and closer contact, and suggests that our intermediate structures lie on this pathway. Moreover, the results show that positive allosteric modulators actuate an allosteric back communication from the TMs to the CRDs.

8

258   To study the effects of G protein on receptor conformational dynamics, we added G_q to Quis-

259   bound mGlu5. The addition of G_q depletes the FRET peak at ~ 0.6 and shifts the receptor to

260   inhabit the ~ 0.75 FRET state observed in Quis and CDPPB and a new FRET state at ~ 0.9

261   (Figure 4c, d, teal). This higher FRET peak is also seen when G_q is added to CDPPB-bound

262   mGlu5 (in the absence of Quis) (Extended Data Figure 11d), agreeing with prior evidence that

263   CDPPB is an agonist-PAM[7]. This peak at ~ 0.9 is stabilized further when G_q is added to mGlu5

264   bound to CDPPB and Quis, (Fully Active, Figure 1a) (Figure 4c, d, dark green). Though G_q

265   can interact with both the Intermediate 2a (FRET ~ 0.6) and Intermediate 3a (FRET ~ 0.75)

266   states, this ~ 0.9 high FRET, Fully Active, state is likely to be a conformation of mGlu5

267   stabilized only in the presence of G protein (Figure 4b, c (example traces are shown in Extended

268   Data Figure 11e)). Though the structure of mGlu5-G_q has not been reported, structures of

269   mGlu2 have been determined in the presence and absence of G protein, and no difference is

270   observed between these mGlu2 structures[12,20]. However, our smFRET data show that, at least

271   for mGlu5, there exists a distinct conformation in the presence of G protein.

272   **Discussion**

273   A long-standing interest in the Family C GPCR field is to understand how the signal to activate

274   is allosterically communicated over a distance of 120 Å from the orthosteric agonist binding

275   site to the TM domain, which contains both the allosteric ligand binding pocket and the G

276   protein binding site. We propose an activation model of mGlu5 and illustrate the effects of

277   agonist, PAM, and G protein on the functional states that range from inactive, to fully active

278   through several intermediates. Upon agonist binding, the upper lobes of the VFT close, while

279   the lower lobes, CRDs, and TMs remain separated (Intermediate 1a, Figure 1a) (Figure 2a,

280   Figure 4b). This Quis-bound Intermediate 1a conformation in mGlu5 is different from the

281   previously observed/proposed intermediate state in other mGlus, where the agonist is bound

282   only to one of the protomers[6,18]. The Quis-bound mGlu5 Intermediate 1a is in equilibrium with

283   the Quis-bound Intermediate 2a (Figure 1a) conformation, with the lower lobes of the VFT,

284   CRDs, and the TMs in close proximity[2] (Figure 2c, Figure 4b). The addition of CDPPB results

285   in asymmetric binding in the presence of Quis (in contrast to the symmetric binding seen in the

286   absence of agonists) and further stabilizes an active conformation of mGlu5 (Intermediate 3a,

287   Figure 1a) (Figure 3a, Figure 4b). Structurally, Intermediate 3a resembles the Intermediate 2a

288   state (Figure 3b), except in the conformation of ICL2 (Figure 3d). Also, in the presence of Quis

289   and CDPPB, there is evidence for a conformation of mGlu5 with reduced intersubunit distance,

290   Intermediate 3b (Figure 1a, Figure 4b). The addition of G protein stabilizes a unique signaling

9

291 conformation as seen from the smFRET data (Fully Active, Figure 1a)(Figure 4b). Previously,

292 smFRET studies have been carried out on CRD-labeled mGlu2 within detergent micelles in

293 the presence of only ligands (G protein was not used)[18,19]. These studies have shown that the

294 activation of mGlu2 with ligands occurs by transitioning through four states and the addition

295 of the PAM does not stabilize a new state but rather increases the occupancy of the active

296 states. Similarly, in mGlu5, PAM alone and agonist alone do not appear to stabilize different

297 states (Extended Data Figure 11d). However, unlike with mGlu2, PAM addition to agonist-

298 bound mGlu5 stabilizes a state not seen with agonist alone (Intermediate 3a, Figure 1a) (Figure

299 4b). Further, the presence of G protein stabilizes a unique state not seen with ligands alone

300 (Fully active, Figure 1a)(Figure 4b), which is yet to be observed structurally. This perhaps

301 indicates slightly different activation intermediates/pathway between different mGlu receptors.

302 In conclusion, the combined structural and dynamic data highlight the allosteric nature of

303 mGlu5 activation, shedding light on the conformational diversity in receptor activation and its

304 interactions with the G protein.

Methods

mGlu5 purification

mGlu5 purification was carried out as previously described[2]. Briefly, human mGlu5 (21–872) with the haemagglutinin (HA) signal peptide, followed by a FLAG epitope tag (DYKDDDD) in the N terminus and a hexahistidine tag at the C terminus was expressed in sf9 cells using the Bac-to-Bac baculovirus expression system (Invitrogen). SF9 cells at density a of 3.5×10^6 cells per milliliter were infected with mGlu5 virus grown for 48h at 27˚C. Cells were harvested by centrifugation and lysed in a hypotonic buffer containing 10mM Tris at pH 7.8 and 1mM EDTA with protease inhibitors. After centrifugation, the pellet was solubilized with 1% (w/v) n-dodecyl-β-D-maltoside (DDM) (Anatrace), 0.1% (w/v) Cholesteryl hemisuccinate (CHS) (Steraloids), 0.2% (w/v) Sodium Cholate (Anatrace), 20 mM HEPES pH 7.5, 750mM NaCl, 30% Glycerol, Iodoacetimide 2mg/ml, protease inhibitor and 10μM MTEP for 1.5 hours at 4˚C. Ca2+ was added and the supernatant after centrifugation was incubated with anti-Flag M1 affinity resin for 2 hours at 4˚C. The resin was washed with 0.1% (w/v) DDM, 0.01% (w/v) CHS, 500mM NaCl, 20 HEPES pH 7.5, 2 mM Ca^{2+},10μM MTEP, followed by 0.1% (w/v) DDM, 0.01% (w/v) CHS, 100mM NaCl, HEPES pH 7.5, 2 mM Ca^{2+} and 10μM MTEP. To exchange detergent to GDN, the column was washed with an increasing concentration of GDN and a decreased concentration of DDM. Finally, the column is washed with 0.2% (w/v) GDN, 0.002%(w/v) CHS, 100mM NaCl HEPES pH 7.5, 2 mM Ca^{2+} and 10 nM MTEP. The protein was eluted in 20mM HEPES pH 7.5, 100mM NaCl, 0.2% (w/v) GDN, 0.002%(w/v) CHS, 200 μg/ml Flag peptide, 5mM EDTA, and 10 nM MTEP. The eluted protein was concentrated in a 50 kDa cut-off Vivaspin (Millipore) and run on a Superose 6 size exclusion column (GE Healthcare) in 20mM HEPES pH 7.5, 100mM NaCl, 0.2% (w/v) GDN, 0.002%(w/v) CHS and 10 nM MTEP. Fractions containing mGlu5 were concentrated, flash frozen, and stored at -80˚C.

Purification of Nb43

Nb43 was purified as described previously[2]. Nb43 in a modified pE-SUMO vector with a PelB leader sequence and SUMO fusion tag was transformed into BL21 E. coli, grown to an OD_{600} of ~ 0.6 at 37 ˚C and induced with 1mM IPTG. The flasks were transferred to 25 ˚C and allowed to express overnight (~12 hours). Bacteria were harvested and Nb43 was purified from the periplasm. Cells were thawed with SET buffer (0.5 M sucrose, 0.5 mM EDTA and 0.2M Tris pH 8.0) and stirred until homogenized. This was followed by the addition of three volumes

11

352   of room-temperature milli-Q water with rapid stirring for 45 min to release the periplasmic

353   contents. Centrifugation was performed to remove cell debris and the supernatant, after the

354   addition of 100 mM NaCl and 10 mM $MgCl_2$, was loaded onto a Ni-NTA resin. The resin was

355   washed with 500 mM NaCl, 20 mM HEPES pH 7.5 and 20 mM imidazole, followed by 100

356   mM NaCl, 20 mM HEPES pH 7.5 and 20 mM imidazole. The SUMO-Nb43 was eluted in 100

357   mM NaCl, 20 mM HEPES pH 7.5 and 250 mM imidazole and, his-SUMO tag was removed

358   by the addition of ULP1. Protein was dialysed overnight into 100 mM NaCl and 20 mM HEPES

359   pH 7.5 at 4°C. Reverse Ni was performed to remove contaminants and uncleaved protein.

360   Finally, Nb43 was subjected to size exclusion chromatography on a Superdex 200 10/30

361   column in 100 mM NaCl and 20 mM HEPES pH 7.5. Monomeric fractions were pooled,

362   concentrated, and flash-frozen in liquid nitrogen.

363

Nanodisc incorporation

365   mGlu5 in GDN was incorporated into MSP2N2 discs using the following ratio: 0.2 Receptor:

366   1 MSP2N2: 120 POPC: POPG (3 POPC: 2 POPG ratio). After 2 hours of incubation on ice,

367   biobeads were added at a ratio of 1:8 mg biobeads: lipids and incubated with shaking at 4°C

368   for 2 hours. The same amount of biobeads was added again and further incubated with shaking

369   at 4°C overnight. The reconstitution mixture was separated from beads and applied on an M1-

370   antiFLAG column. After washing with 100mM NaCl, 20 HEPES pH 7.5 and 15 mM Ca^{2+} to

371   remove empty discs, the reconstituted protein was eluted in 100mM NaCl, 20 HEPES pH 7.5,

372   200 μg/ml Flag peptide, and 5mM EDTA. Nanodisc incorporated mGlu5 was concentrated,

373   and injected on a Superose 6 10/30 gel filtration column in 100mM NaCl, 20mM Hepes pH

374   7.5. Monomeric peak fractions were collected and concentrated to ~ 5mg/mL for imaging.

375

GTP turnover assay

377   Analysis of GTP turnover was performed by using a modified protocol of the GTPase-Glo[TM]

378   assay (Promega) described previously[21]. In the presence (20 uM) or absence of ligand, mGlu5

379   (1 μM in GDN and 0.5 μM in nanodisc) and G_i (1 μM for mGlu5 in GDN and 0.5 μM for

380   mGlu5 in Nanodisc) was mixed in 20 mM HEPES, pH 7.5, 50 mM NaCl, 0.01% GDN/ 0.001%

381   CHS (or no detergent for nanodisc sample), 100 μM TCEP, 10 μM GDP and 10 μM GTP and

382   incubated at room temperature for 120 minutes. GTPase-Glo-reagent was added to the sample

383   and incubated for 30 minutes. Luminescence was measured after the addition of detection

384   reagent and incubation for 10 min at room temperature using a *SpectraMax Paradigm* plate

385   reader.

HDX-MS

Hydrogen–deuterium exchange labeling reaction

Purified mGlu5 at 60 µM [monomer] was diluted to 20 µM [monomer] in 100 mM NaCl, 20 mM HEPES, 0.05% GDN/0.005% CHS to match the concentration of mGlu5 in nanodisc (also 20 µM [monomer]). Subsequently, mGlu5 in detergent was further diluted 1:1 to 10 µM [monomer] with 10 mM monosodium glutamate, 100 mM NaCl, 20 mM HEPES, 0.05% GDN/0.005% CHS, pH 7.5, such that the final concentration of glutamate in this sample was 5 mM. An equivalent mGlu5 sample in detergent was also prepared in the absence of glutamate. Similarly, mGlu5 in nanodiscs was diluted 1:1 to 10 µM [monomer] with 10 mM monosodium glutamate, 100 mM NaCl, 20 mM HEPES, pH 7.5. All samples were incubated for 30 minutes at room temperature.

To prepare deuterated buffer, 5 mL of 10X buffer of 1 M NaCl, 200 mM HEPES, with or without 100 mM monosodium glutamate, at pH 7.5 was lyophilized overnight and then resuspended in D_2O. 1X buffers were prepared by a 1:9 dilution with D_2O, and a buffer of 5 mM monosodium glutamate was prepared by combining those same buffers in a 1:1 ratio. To prepare quench buffer, 27 mg of zirconium (IV) oxide, used for lipid extraction, was combined with 1 mL of quench buffer (3 M urea, 20 mM TCEP, pH 2.4), vortexed, and left on ice.

To initiate exchange, samples were diluted 1:10 into D_2O buffer and quenched 1:1 with cold quench buffer for a total sample volume of 80 µL and left on ice. At each time point, 0.8 µL of porcine pepsin (10 mg/ml; Sigma Aldrich) and 0.8 µL of aspergillopepsin (10 mg/ml; Sigma Aldrich) were added to each sample, which was rapidly vortexed and returned to ice for 3.5 minutes. To remove zirconium (IV) oxide, each sample was transferred to a temperature-controlled centrifuge, and spun up to maximum speed (21.1 x g); the supernatant was then transferred to a new tube and flash frozen in liquid N_2. Samples were stored at –80 °C prior to LC/MS analysis. Proteases were resuspended in 100 mM NaCl, 20 mM HEPES, pH 7.5 to 10 mg/ml and filtered (0.22 µm filter, Corning), aliquoted, flash frozen, and stored at –80 °C prior to use.

Liquid chromatography/mass spectrometry analysis

Samples were thawed and injected into a cooled valve system (Trajan LEAP) coupled to an LC (Thermo Ultimate 3000) flowing buffer A (0.1% formic acid) at 200 µL/min. The valve chamber, trap column, and analytical column were kept at 2 °C.

418   Peptides were desalted for 4 minutes on a trap column (1 mM ID x 2 cm, IDEx C-128) manually

419   packed with POROS R2 reversed-phase resin (Thermo Scientific). Peptides were then

420   separated on a C18 analytical column (Waters Acquity UPLC BEH C18 Column, pore size 130

421   Å, particle size 1.7 μm, 2.1 mm ID X 50 mm) with buffer B (100% acetonitrile, 0.1% formic

422   acid) flowing at a rate of 40 µL/min, increasing from 5% to 40% over the first 14 minutes and

423   from 40% to 90% B over 30 s, and dropped to 5% B after 2.5 min. After 30 s, two sawtooth

424   gradients (5% to 40% B over 30 s, 40% to 90% B over 30s, hold at 90% B for 30 s, drop to 5%

425   B over 30 s, hold at 5% B for 30s) were performed. Peptides were eluted into a Q Exactive

426   Orbitrap Mass Spectrometer (ThermoFisher) operating in positive ion mode (MS1 settings:

427   resolution 140000, AGC target 3e6, maximum IT 200 ms, scan range 300-1500 m/z). For

428   tandem mass spectrometry, mGlu5 samples were analyzed using the MS1 settings described

429   above, with resolution 70000, and MS2 settings as follows: resolution 17500, AGC target 2e5,

430   maximum IT 100 ms, loop count 10, isolation window 2.0 m/z, NCE 28, charge state 1 and >8

431   excluded, dynamic exclusion 15.0 s.

432   Sample time points were injected in non-consecutive order, and after every injection, a

433   shortened, blank injection was performed to monitor for protein carryover. Briefly, blank runs

434   were carried out with buffer A flowing at 300 µL/min. Any remaining material within the

435   sample loop, as well as wash buffer, was desalted for 2 minutes on the same trap column; the

436   remaining material was then separated on the same C18 analytical column flowing at a rate of

437   40 µL/min, increasing from 5% to 40% over the first 1.5 minutes and from 40% to 90% B over

438   30 s, and dropped to 5% B after 30 s. After 30 s holding at 5% B, two sawtooth gradients (5%

439   to 40% B over 30 s, 40% to 90% B over 30s, hold at 90% B for 30 s, drop to 5% B over 30 s,

440   hold at 5% B for 30s) were then performed.

441

Peptide identification and analysis

443   MS2 data were processed using Byonic (Protein Metrics), resulting in a reference list of

444   peptides, including several peptides containing glycosylation sites. Hydrogen–deuterium

445   exchange data were analyzed in HD-Examiner (version 3.1) using default settings, and uptake

446   values were adjusted to reflect that the final samples were 90% deuterated. Where necessary,

447   peptide retention times histograms were manually adjusted to ensure consistency across all

448   time points. Uptake summary data were exported from HD-Examiner and used to create uptake

449   curves and Woods plots using Python scripts. A difference in deuteration of less than 10%

14

450   between the two conditions was not considered significant, as indicated by horizontal dashed

451   lines on Woods plots.

452

453   **Cryo-EM sample preparation and data acquisition**

454   mGlu5 in nanodisc was incubated with Quis alone (and Nb43), Quis and CDPPB (G_qiN and

455   Nb43), or CDPPB alone for two hours at room temperature. For grid preparation, 3 μL of

456   purified mGlu5 (with the different ligands) at 5 mg/ml was applied on glow-discharged holey

457   carbon gold grids (Quantifoil R1.2/1.3, 200 mesh). The grids were blotted using a Vitrobot

458   Mark IV (FEI) with 3 s blotting time and blot force 3 at 4˚C and 100% humidity and plunge-

459   frozen in liquid ethane.

460

461   **Image processing and 3D reconstructions**

462   For all three samples, namely CDPPB-bound mGlu5, Quis and Nb43 bound mGlu5, and

463   Quis+CDPPB bound mGlu5, cryo-EM data were collected on a Titan Krios electron

464   microscope operating at 300 kV and equipped with a K3 direct electron detector. Movies were

465   acquired at Counting mode with a calibrated pixel size of 1.111 Å/pixel and a total dose of

466   ~51.6 electrons/Å², fractionated across 50 frames (Extended Data Figure 2, 6, and 7, Extended

467   Data Table 1).

468   Single particle data processing was performed using *cryoSPARC 3.3.2*[22]. Initially, motion

469   correction and CTF estimation were carried out using *Patch Motion Corr* and *Patch CTF*,

470   followed by template-based particle picking utilizing previously determined mGlu5 structures

471   (EMD-0345 or EMD-0346). The detailed data processing workflows can be found in Extended

472   Data Figures 2, 6, and 7. Picked particles were sorted using 2D classification, ab initio, and

473   heterogenous refinement. For each structure/conformation, we applied both global non-

474   uniform refinement[23] and local refinement on the CRD-TM region. The final maps, generated

475   with *UCSFChimera*[24], are composite maps of the global non-uniform refinement and the

476   locally refined CRD-TM region. Map sharpening was performed with *Autosharpen* within

477   *Phenix*[25,26].

478   Lastly, local resolution estimation and 3DFSC were employed to assess the local resolution

479   and orientation distribution of the final dataset[27].

480

481

482

Model building and refinement

The initial template was mGlu5 from PDB codes 6N51 and 6N52. Ligand coordinates and geometry restraints were generated using *phenix.elbow*[25]. *Coot*[28] was used for iterative model building and the final model was subjected to global refinement and minimization in real space using *phenix.real_space_refine* in *Phenix*[25]. FSC curves were calculated between the resulting model and the half map used for refinement as well as between the resulting model and the other half map for cross-validation (Extended Data Figures 2, 6, and 7). The final refinement parameters are provided in Extended Data Table 1.

3DVA and 3DFlex Analysis

CryoSPARC's 3D Variability Analysis (3DVA) was used to investigate the conformational heterogeneity in the final data sets for Quis-bound or Quis + CDPPB-bound active state[14]. The particles used for final non-uniform refinement were processed by 3DVA with three modes, and a mask encompassing the whole receptor, including the nanodisc. Following 3DVA, the three principal components were subjected to 3DVA Display using simple output mode and 20 frames. The resolution was low pass filtered to 5Å to avoid noise dominating the determination of eigenvectors. The results were visualized using *UCSFChimera* (SI Video 1).

CryoSPARC's 3D Flexible Refinement (3DFlex) was also used to investigate and confirm the conformational heterogeneity in the Quis+CDPPB bound active state[15]. For 3DFlex on the whole receptor, the particles used for the final non-uniform refinement were cropped into 256 pixels (1.48Å/pixel) for reconstruction and 128 pixels (2.95Å/pixel) for training. A mask, which encompassed the whole receptor including the nanodisc, was divided into 20 tetrahedral cells to prepare the mesh. For 3DFlex training, we optimized different parameters and ended up using 3 latent dimensions, 0.1 rigidity prior strength, and 10 latent centering strength. The latent distributions along 3 dimensions are visualized using *UCSFChimera* (SI Video 2).

For 3DFlex on the CRD+TM regions, the particles used for TM local refinement were kept in their original box size for data prep and cropped into 170 pixels (2.22Å/pixel) for training. A mask encompassing the TM regions (Extended Data Figure 6a), excluding the nanodisc, was divided into 40 tetrahedral cells to prepare the mesh. For 3DFlex training, we optimized different parameters and ended up using 3 latent dimensions, 0.5 rigidity prior strength, and 10 latent centering strengths. The latent distributions along 3 dimensions are visualized using *UCSFChimera* (SI Video 2).

Minimal Cysteine expression and purification

We developed a minimal cysteine (minCys) construct of mGlu5, to enable site-specifically labeling. In mGlu5, two Cys residues, one in the intracellular end of TM4 ($C691^{4.30}$) and the other in ICL2 ($C681^{ICL2}$) appear to be exposed to being labeled, mutation of these to Ala largely abolished background labeling. Human mGlu5 (21–872) with the haemagglutinin (HA) signal peptide, followed by a FLAG epitope tag (DYKDDDD) in the N terminus and a hexahistidine tag at the C terminus was cloned into pcDNA-Zeo-tetO. Two native cysteine residues were mutated to make the minimal cysteine construct ($C691^{4.30}$A and $C681^{ICL2}$A) and for bimane spectroscopy studies a single $C691^{4.30}$A mutant was cloned. For smFRET studies, an engineered Cys was introduced into the CRD (560C). The bimane and smFRET constructs were transfected into Expi293F (Thermo Fisher) cells stably expressing the tetracycline repressor using an Expifectamine transfection kit (Thermo Fisher) following the manufacturer's recommendations with the following modifications. Two days post-transfection, mGlu5 expression was induced with doxycycline (4 μ/ml and 5 mM sodium butyrate) in the presence of 1 μM MTEP. Cells were harvested 30 hours post-induction and stored at -80°C until use. Further purification and nanodisc incorporation were performed following the protocol described earlier for pellets from insect cells.

Bimane Spectroscopy

WT mGlu5 or $C691^{4.30}$A mutant in nanodisc at 10 μM was incubated with a 10-molar excess of bimane at room temperature for one hour. The excess label was removed using size exclusion chromatography on a Superose 6 10/300 Increase column in 20 mM HEPES pH 7.5 and 100 mM NaCl. Bimane-labeled mGlu5 at 0.1 μM was incubated with ligands (10 uM) for one hour at room temperature. Fluorescence data were collected at room temperature in a 150 μL cuvette with *FluorEssence v3.8 software* on a Fluorolog instrument (*Horiba*) in photon-counting mode. Bimane fluorescence was measured by excitation at 370 nm with excitation and emission bandwidth passes of 4 nm. The emission spectra were recorded from 410 to 510 nm with a 1 nm increment and 0.1 s integration time.

smFRET sample preparation and data collection

Nanodisc incorporated minCys mGlu5 (with residues $C691^{4.30}$ and $C681^{ICL2}$ mutated) with an introduced Cys at position 560 was incubated with 5-molar excess of donor (LD555) and 10-molar excess acceptor (LD655) at room temperature for 20 min. Following the incubation with

17

550   5 mM cysteine for 10 min, the sample was subjected to size exclusion chromatography on a

551   Superose 6 10/300 Increase column in 20 mM HEPES pH 7.5 and 100 mM NaCl, for the

552   removal of excess labels.

553   mPEG (Lysan Bio) was used to passivate glass coverslips (VWR) and, further doped with

554   biotin PEG16 to inhibit nonspecific protein adsorption. The coverslips, before each experiment,

555   were incubated with *NeutrAvidin* (Thermo Fisher), followed by 10 nM biotinylated antibody

556   (mouse anti-FLAG, GenScript). Chambers were flushed to remove reagents, between each

557   conjugation step. The anti-FLAG antibody was diluted and washed in 50 mM NaCl, 10 mM

558   Tris, pH 7.5. Labeled mGlu5 was diluted ~ 100-fold and applied to coverslips to achieve

559   optimum surface immobilization (~400 molecules in a 2,000 μm^2 imaging area). Unbound

560   receptors were washed away with buffer. smFRET imaging was performed in an imaging

561   buffer consisting of 3 mM Trolox, 100 mM NaCl, 2 mM $CaCl_2$, 20 mM HEPES pH 7.5, and

562   an oxygen scavenging system (0.8% dextrose, 0.8 mg/ml glucose oxidase, and

563   0.02 mg/ml catalase). Samples were imaged with a 1.49 NA 60X objective (Olympus) on a

564   total internal reflection fluorescence microscope with 100 ms time resolution unless stated

565   otherwise. Lasers at 532 nm (Cobolt) and 633 nm (Melles Griot) were used for donor and

566   acceptor excitation, respectively. Fluorescence was passed through a Chroma ET550lp filter

567   and split into donor and acceptor signals with a Chroma T635lpxr. FRET efficiency was

568   calculated as $(I_A-0.1I_D)/(I_D+I_A)$, in which I_D and I_A are the donor and acceptor intensity,

569   respectively, after background subtraction. Imaging was with 100 millisecond acquisition time

570   (10 Hz) with a Photometrics Prime 95B CMOS camera.

571

572   **smFRET data processing**

573   The fluorescence movies were analyzed with SPARTAN version 3.7[29]. Donor and acceptor

574   channels were aligned using the first 10 frames of each movie while excluding particles closer

575   than 3.5 pixels using an integration window of 12 pixels. Traces showing single-donor and

576   single-acceptor photobleaching with a stable total intensity for longer than 5 seconds

577   (50 frames), SNRbg > 15, and donor/acceptor correlation coefficients < 0.0 were collected

578   (20–30% of total molecules per imaging area). Nonlinear filter[30] was used for smoothing

579   individual traces with the following filter parameters: window = 2, M = 2, and P = 15

580   for histograms. smFRET histograms were compiled from $\geq$100 molecules per condition (100

581   millisecond time resolution). Error bars in the histograms represent SEM from $\geq$4 independent

582   movies. To ensure that traces of different lengths contribute equally, histograms from

583   individual traces were normalized to one before compiling. Histograms were fit to 3 Gaussians

584   (based on the Akaike information criteria, Figure 11b) using *Graphpad Prism 9*.

585

586

587   **Data availability**

588   The data that support this study are available from the corresponding authors upon request. The

589   cryo-EM density maps have been deposited in the Electron Microscopy Data Bank (EMDB)

590   under accession codes EMDB-41092, EMDB-41099, EMDB-41139 and EMDB-41069. Model

591   coordinates have been deposited in the Protein Data Bank (PDB) under accession number

592   8T7H, 8T8M, 8TAO, 8T6J.

593

594   **Acknowledgements**

598
599   **Author Contributions**

600   KKK and BKK conceived the project. KKK prepared samples, froze grids and collected

601   cryoEM data with help from CZ and EM. KKK and JX developed the minimal cysteine mGlu5

602   construct and performed bimane studies and, made smFRET samples with help from ESO.

603   HW processed cryoEM data and performed the 3DVA and 3dflex analysis.

604   CH collected and analysed smFRET data under the supervision of EYI.

605   NRL performed and analysed the HX data under the supervision of SM.

606   AK helped with structure analysis.

607   KKK, HW and BKK wrote the manuscript with inputs from all the authors.

608

609   **Competing Interests**

610   Brian Kobilka is co-founder of and consultant for ConfometRx. The remaining authors declare

611   no competing interest.

702 **Main Text Figures**

703 **Fig 1: Sequential activation of mGlu5 in lipid environment**

704

705 a) Using the data from this study we propose a model for mGlu5 activation. The addition of

706 an orthosteric agonist (e.g. glutamate) results in the closing of the upper lobe (Intermediate

707 1a). This conformation is in equilibrium with a conformation in which the twisting of the

708 lower lobe brings the CRDs and TMs in close proximity (Intermediate 2a). The addition of

709 a PAM stabilizes the CRDs and TMs, including ICL2 in an active conformation

710 (Intermediate 3a). Intermediate 3a is in equilibrium with Intermediate 3b, which is

711 characterized by a smaller intersubunit distance. In the presence of an orthosteric agonist,

22

712   the PAM binds to one protomer (Intermediate 3a and 3b), whereas in its absence the PAM

713   binds to both the protomers symmetrically (Intermediate 1b). Further addition of G protein

714   to the agonist and PAM-bound mGlu5 results in the stabilization of a unique fully active

715   conformation of the receptor (Fully active).

716 b) Cryo-EM density and model of Quis-bound mGlu5 in nanodisc, representing an

717   Intermediate 1a state, where Quis is bound to the VFTs, however, the CRDs and TMs are

718   far apart mimicking the inactive state. VFT binding Nb43 is shown in yellow.

719 c) Cryo-EM density and model of nanodisc-incorporated Quis-bound mGlu5, Intermediate 2a

720   state. The CRDs and TMs are in an active conformation (close together).

736

737

738

23

739   **Fig 2: Structures of Quis-bound conformations of mGlu5 in nanodisc**
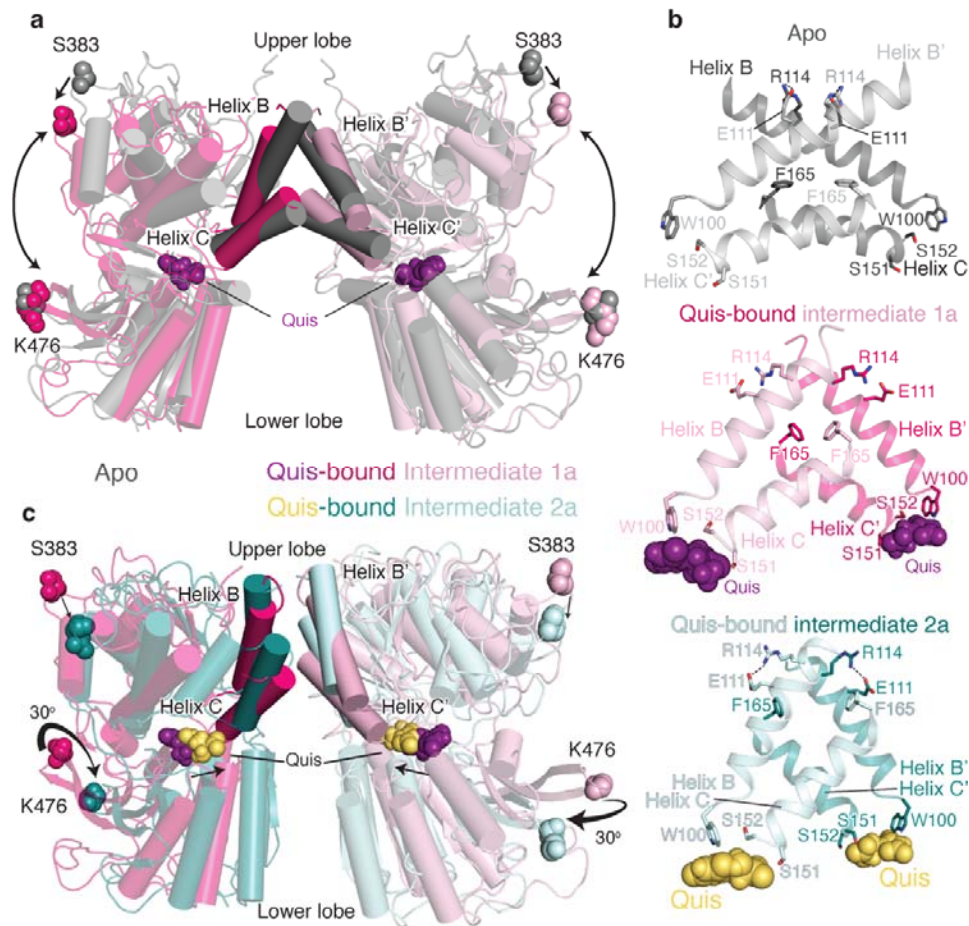

740

741   a) VFTs of Apo (grey, PDB: 6N52) and Quis-bound Intermediate 1a are overlayed. Upon

742   Quis binding the upper lobe closes, as seen by the movement of S383, whereas not much

743   change is seen in the lower lobe (comparing K476 between the structures). Also shown is

744   the comparison of the B and C helices at the intersubunit interface in the Apo and Quis-

745   bound Intermediate 1a state.

746   b) The intersubunit rearrangement upon Quis binding reorients the B and C helices leading to

747   a reduction in the helix angle. Top: Apo, Middle: Quis-bound Intermediate 1a and Bottom:

748   Quis-bound Intermediate 2a. Residue R114 interacts with E111 from the adjacent protomer

749   in the Apo state and within the same protomer in the Quis-bound Intermediate 2a. The

750   residue F165 is shown to illustrate the change in the position of the C helix. There is a

751   downward movement of W100 towards Quis in Intermediates 1a and 2a. Due to the lower

752   lobe rotation in Intermediate 2a, a further inward movement of Quis is seen.

24

753   c) Overlay of VFTs of Quis-bound Intermediate 1a and Quis-bound Intermediate 2a showing

754   a small change in the upper lobe (movement of S383). The lower lobes twist 30° and move

755   closer together as seen by comparing K476 between the structures. The B and C helices at

756   the protomer-protomer interface in the Quis-bound Intermediate 2a state show an upward

757   shift compared to the Quis-bound Intermediate 1a. This likely is the result of the inward

758   movement of Quis (from purple to yellow) and the rearrangement of the lower lobe.

Fig 3: Structural changes of upon PAM binding to mGlu5
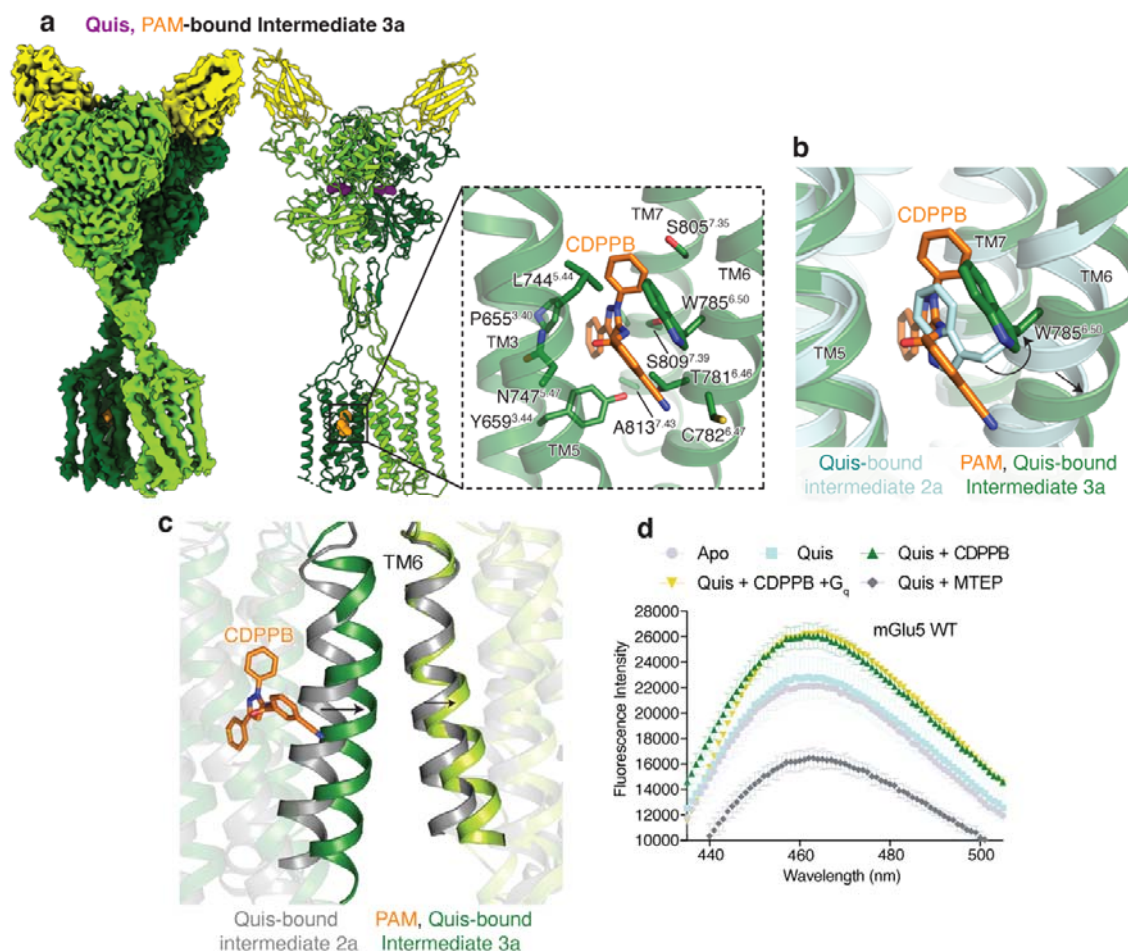

a) Cryo-EM density and model of CDPPB (orange) and Quis-bound mGlu5 in a nanodisc. The structure represents the Intermediate 3a state with the CRDs and TMs in close proximity. Nb43 is shown in yellow. Insert: Binding pocket of CDPPB in the TM region showing residues within 4Å as sticks.

b) CDPPB binding to the TM causes the rearrangement of $W785^{6.50}$ to accommodate the ligand.

c) Quis-bound Intermediate 2a and CDPPB, Quis-bound Intermediate 3a structures show differences in the conformation of TM6 at the protomer interface.

d) Bimane spectra of mGlu5 in nanodiscs labeled at positions $C691^{4.30}$ (end of TM4) and $C681^{ICL2}$. Adding Quis (cyan) results in no change in the spectra compared to Apo (grey). However, Quis and CDPPB increase the fluorescence (dark green), indicating a change in the ICL2 environment. Further addition of G_q does not result in a change in the bimane

26

793   spectrum (yellow). The addition of Quis and MTEP causes a decrease in fluorescence. Data

794   represented as mean ± SD, n = 3 individual.

795   **Fig 4: Ligand stabilised conformations of mGlu5 in nanodisc**
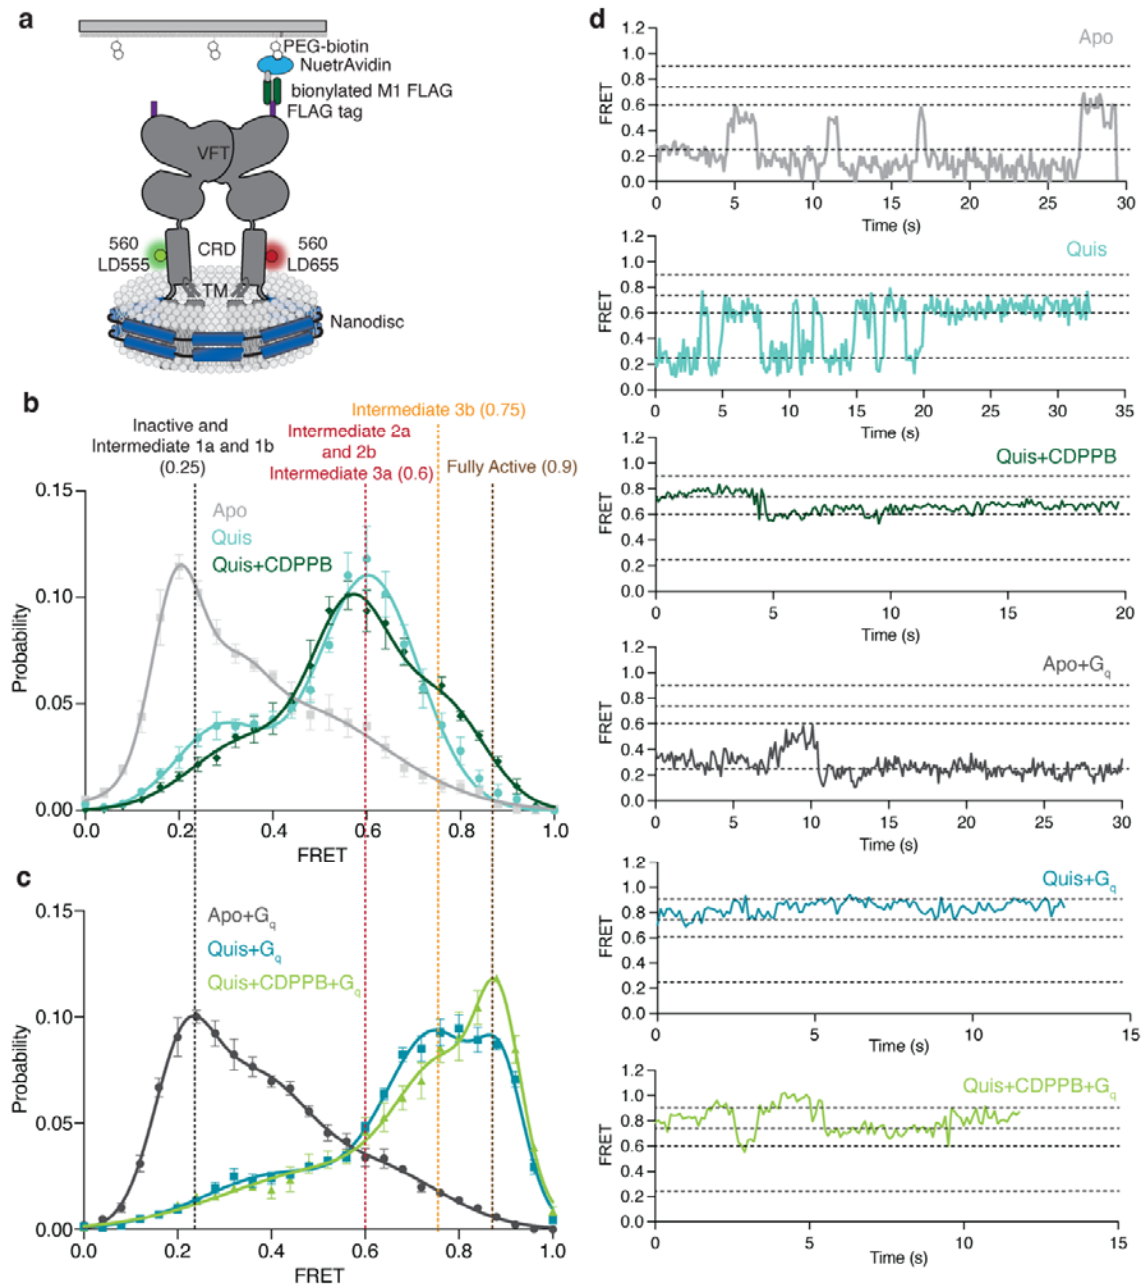

796

797   a) A schematic representation of the smFRET experiment.

798   b) In the Apo state (grey) a dominant inactive FRET peak at ~ 0.25 is observed (N=319). The

799   binding of the agonist, Quis results in the appearance of a ~ 0.6 FRET state (Intermediate

800   2a, cyan, N=392) with a minor peak at ~ 0.25 (Intermediate 1a). The addition of CDPPB

801   to Quis-bound mGlu5 stabilizes the ~ 0.6 FRET state (Intermediate 3a), decreases the

802   occupancy of the ~ 0.25 state, and results in the appearance of a new FRET peak at ~ 0.75

803   (Intermediate 3b, dark green, N=329). High FRET (~ 0.6 and ~ 0.75) represents the active

804   state population of the receptor with the CRDs and TMs in close proximity. Histograms are

805   shown with a 3-Gaussian fit to the data and represented as mean ± SEM.

806 c) The coupling of G_q to Apo (dark grey, N=329) remains largely unchanged compared to

807   Apo alone (Figure 4b), while the addition of G_q in the presence of Quis results in the near

808   complete abrogation of the ~ 0.6 FRET peak in favor of the ~ 0.75 peak (Intermediate 3b)

809   and a new peak at ~ 0.9 (Fully Active) (teal, N=306), which is further stabilized in the

810   presence of CDPPB (light green, N=317). Histograms are shown with a 3-Gaussian fit to

811   the data and represented as mean ± SEM.

812 d) Example FRET traces are shown for each ligand condition.

829   **Extended Data Figures**

830   **Extended Data Figure 1: mGlu5 activation in detergent compared to lipid environment**
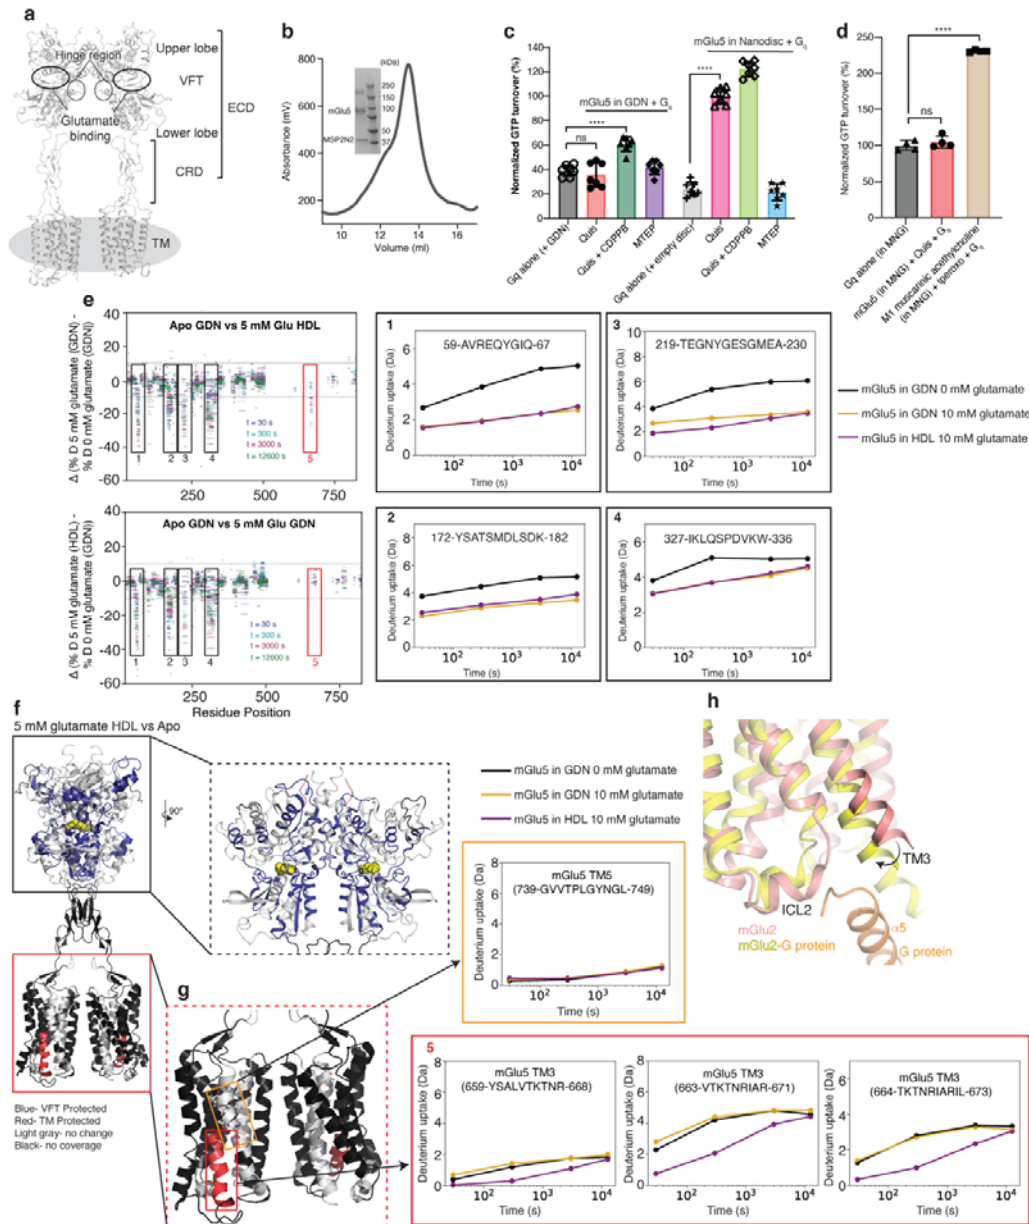

831

832   (a) Structural domains of mGlu5.

833   (b) SEC trace and SDS-PAGE gel of mGlu5 in nanodisc.

834   (c) GTP turnover assay showing mGlu5 induced G_q turnover. In the presence of agonist Quis,

835   mGlu5 in detergent does not induce significant G_q (red) turnover compared to G_q alone

836   (grey). The addition of Quis and CDPPB (dark green) to mGlu5 in detergent results in a

837   small but significant increase in G protein turnover. With mGlu5 in nanodiscs, the addition

29

838 of Quis significantly increases G_q turnover (magenta). Quis and CDPPB (light green)

839 further increase the GTP turnover of G_q. The negative allosteric modulator, MTEP inhibits

840 turnover in mGlu5 nanodiscs condition (blue). Data represented as mean ± SD, ns= 0.4124,

841 $p < 0.0001$****, unpaired t-test (two-tailed), n= 7 individual experiments (data

842 normalization was done with the average value of Quis-bound mGlu5 in nanodiscs as 100%

843 and receptor alone as 0%).

844 (d) In the presence of the agonist iperoxo, muscarinic acetylcholine M1 receptor (in MNG)

845 induces significant GTP turnover in G_q ($p < 0.0001$****). But no difference is seen with

846 Quis-bound mGlu5 (in MNG) and G_q (ns= 0.5374). Data represented as mean ± SD, p

847 values are from unpaired t-test (two-tailed), n= 4 individual experiments. Data

848 normalization was done with the average value of G_q in MNG as 100% and buffer alone as

849 0%.

850 (e) HDX-MS data is plotted as the difference in the percent deuteration for a given peptide at

851 a given time point against the sequence position for Apo mGlu5 in detergent (GDN) vs 5

852 mM glutamate-bound mGlu5 in detergent (GDN) (top) and Apo mGlu5 in detergent (GDN)

853 vs 5 mM glutamate-bound mGlu5 in nanodisc (HDL) (bottom). Black boxes numbered 1-

854 4 are example regions in the VFT that show no difference between mGlu5 in detergent

855 (GDN) and nanodisc (HDL) (the corresponding deuterium uptake plots are shown on the

856 right). The red box is a region in the TM that shows a difference between agonist-bound

857 mGlu5 in detergent and nanodisc (HDX-MS exchange curves shown in Extended Figure

858 1g).

859 (f) HDX-MS changes in Apo mGlu5 in detergent and agonist-bound mGlu5 in nanodisc are

860 plotted onto the mGlu5 structure (PDB code: 6N51).

861 (g) Colored red is the TM3 region, where peptides were observed in HDX-MS measurements.

862 Deuterium uptake plots of these TM3 peptides (red box in Extended Fig 1e) show that Apo

863 (black) and receptor in GDN in the presence of 5 mM glutamate (yellow) overlay well.

864 Whereas, TM3 peptides of mGlu5 in nanodisc (magenta) do not overlay with Apo. Shown

865 in the orange box is a TM5 peptide showing no change in deuterium uptake between the

866 conditions.

867 (h) Agonist-bound mGlu2 (PDB code: 7MTR) is overlayed with agonist-bound mGlu2-G

868 protein complex (PDB code: 7MTS) showing conformational changes in the intracellular

869 region of TM3.

870

Extended Data Figure 5: mGlu5 transmembrane changes upon activation
a) Overlay of Apo (grey, PDB: 6N52) and Quis-bound Intermediate 1a states show minimal changes in the CRDs and TMs. Arrows represent the movement of every 5 Cα atoms from Apo to Intermediate 1a.

b) Large changes in the CRDs and TMs are seen when comparing the Quis-bound Intermediate 1a and the Quis-bound Intermediate 2a states. Arrows represent the movement of every 5 Cα atoms from Intermediate 1a state to Intermediate 2a.

c) The CRDs in the Quis-bound Intermediate 1a structure are separated by ~ 38 Å (as measured at residue E527). In the Quis-bound Intermediate 2a state, the twisting of the lower lobe enables the CRDs (~ 11 Å at residue E527) and TMs to move adjacent to each other.

d) The TMs in the Quis-bound Intermediate 1a structure are far apart with TM5 being the most proximal helix pair (~ 21 Å). In the Quis-bound Intermediate 2a state the TMs of the protomers, in addition to moving closer to each other, rotate ~ 20º to form a TM6-TM6 interface, a hallmark of Family C activation.

34

936 **Extended Data Figure 6: Cryo-EM data processing workflow and resolution assessment**

937 **of CDPPB, Quis-bound map**
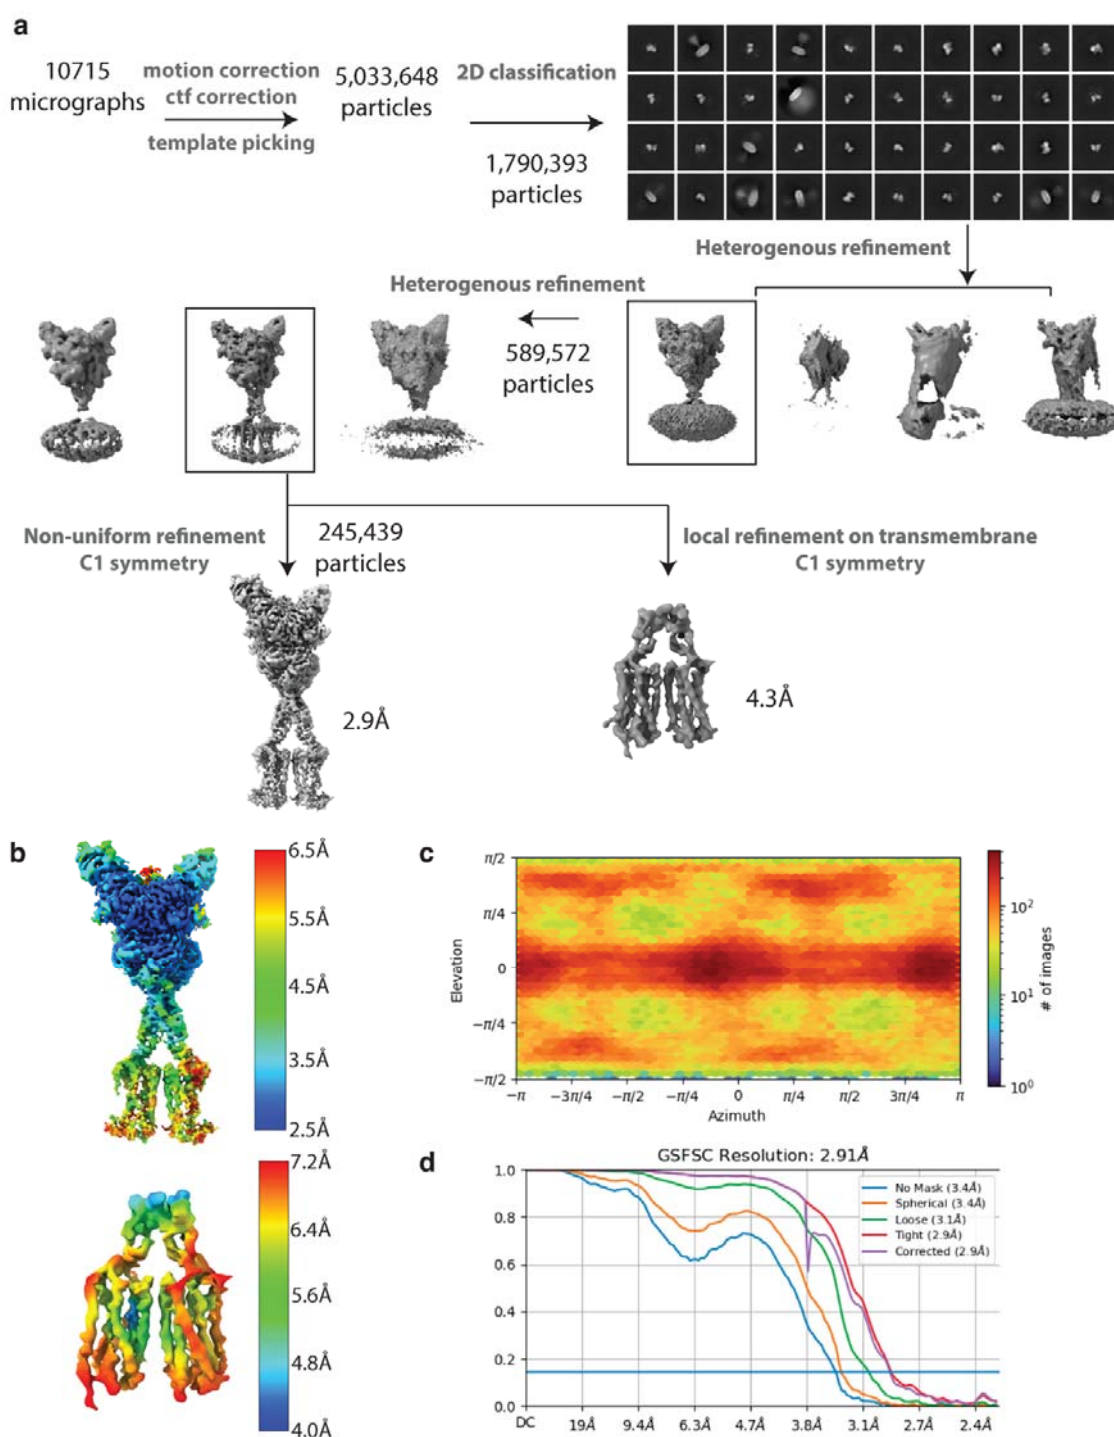

938

946

947   (a) Workflow of cryo-EM data processing to obtain CDPPB-bound mGlu5 Intermediate 1b

948   structure.

949   (b) Local resolution maps of the CDPPB-bound mGlu5 structure.

950   (c) Angular particle distribution of the structure.

951   (d) Gold-standard FSC curves of the CDPPB-bound mGlu5 structure.

952   **Extended Data Figure 8: CDPPB-bound structure analysis**

953

954   (a) Cryo-EM density and model of CDPPB-bound mGlu5 Intermediate 1b in a nanodisc. Also
955   shown is the density for the two bound CDPPB, one in each TM domain.

956   (b) Comparison of the allosteric binding pocket in Apo (PDB:6N52, grey) and CDPPB-bound
957   mGlu5 (dark blue), shows changes in TM5 (N747$^{5.47}$) and TM6 (W785$^{6.50}$) to accommodate
958   CDPPB (slate).

959   (c) Overlay of CDPPB from Intermediate 1b (dark blue) and Intermediate 3a structures
960   showing minimal changes in the conformation of TM5 and TM6.

37

961 (d) Residues that interact with CDPPB only in Intermediate 3a are shown in green (T781$^{6.46}$

962 and C782$^{6.47}$) and those that interact with CDPPB only in Intermediate 1b are shown in

963 blue (I751$^{5.51}$).

964 **Extended Data Figure 9: CDPPB, Quis-bound structural analysis**
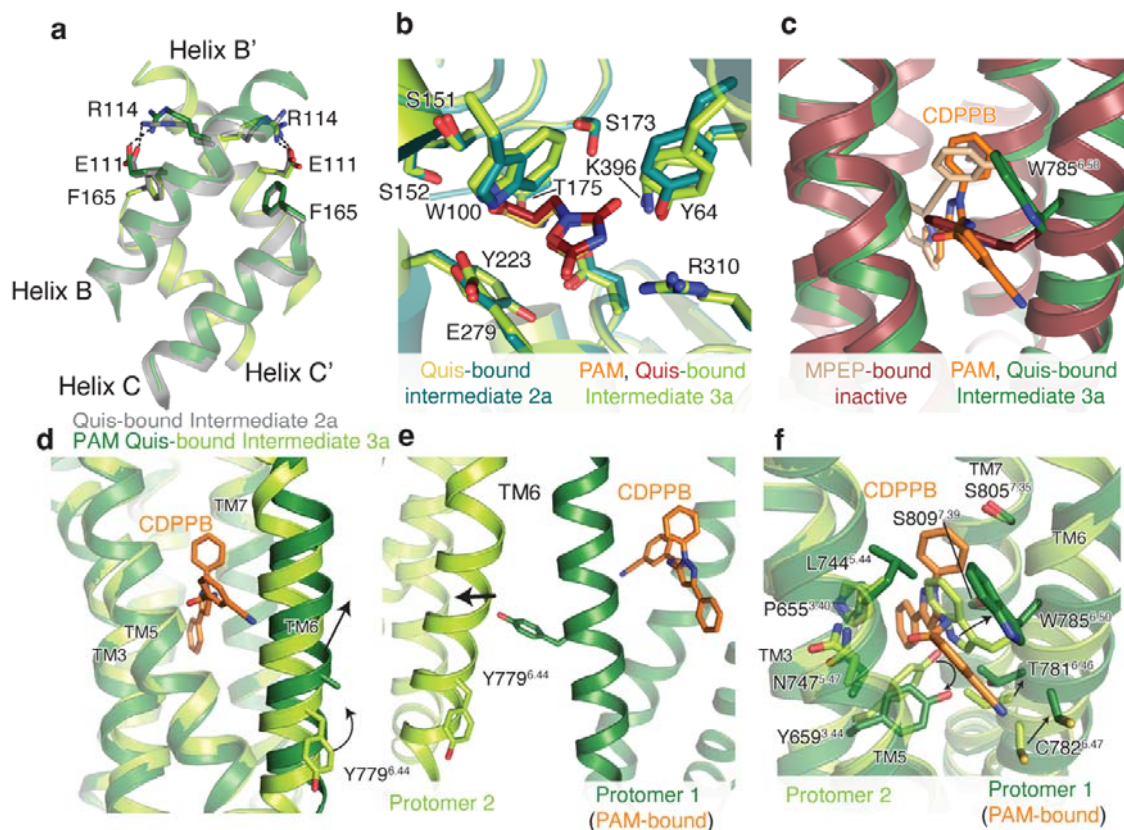

965

966 (a) Overlay of intersubunit B and C helices in Quis-bound Intermediate 2a state and CDPPB,

967 Quis-bound Intermediate 3a structure. Residues R114 and E111 interact in both structures.

968 (b) Overlay of Quis binding pocket in Quis-bound Intermediate 2a and CDPPB, Quis-bound

969 Intermediate 3a structures, showing no difference in the ligand pocket.

970 (c) The conformation of residue W785$^{6.50}$ is different in the structure with the NAM, MPEP

971 (PDB: 6FFI, brown) compared to that with the PAM, CDPPB (dark green).

972 (d) TM6 in the CDPPB-bound Protomer 1 has moved outward compared to Protomer 2 with

973 no CDPPB bound. In CDPPB-bound Protomer 1, Y779$^{6.44}$ points towards the intersubunit

974 interface, as seen in (e). Though we cannot model the Y779$^{6.44}$ sidechain in Protomer 1 with

975 confidence due to a lack of good density, we have added the most frequently occurring rotomer

976 of Tyr.

38

977   (f) Comparison of the allosteric pocket in CDPPB-bound protomer (protomer 1, dark green and

978   CDPPB shown as orange) and the protomer with no CDPPB (protomer 2, green).

979   **Extended Data Figure 10: Characterisation of minimal cysteine mGlu5 and ICL2**

980   **conformation**
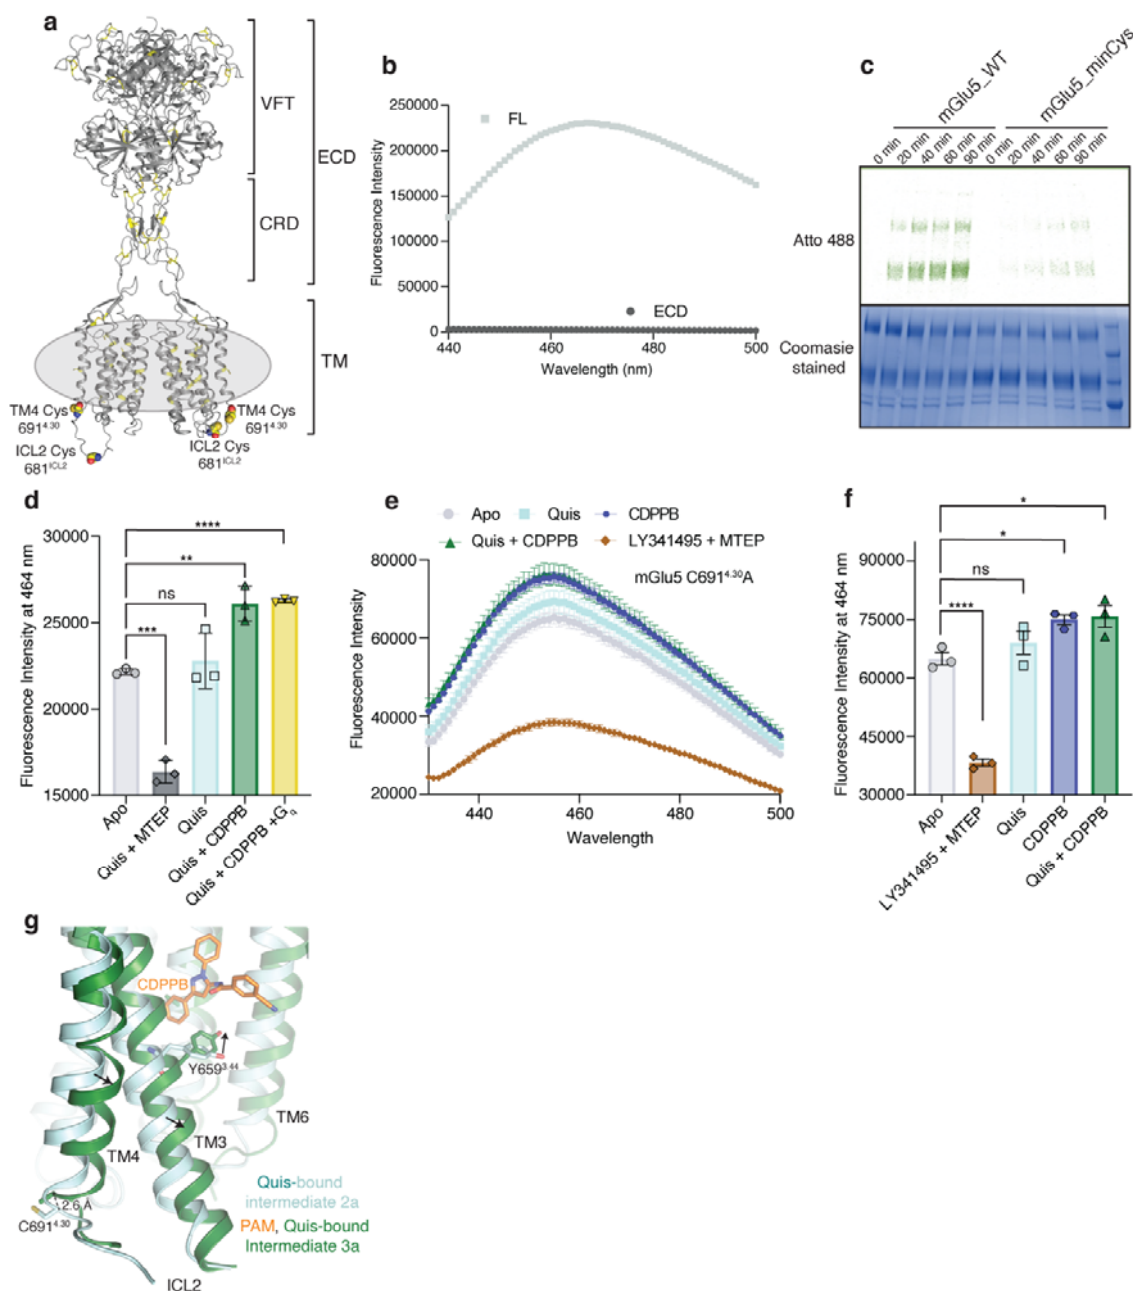

981

982   (a) Residues Cys691$^{4.30}$ and Cys681^{ICL2} that contribute to background labeling with dyes are

983   shown as spheres. Other cysteine residues in the receptor are shown as yellow sticks.

984   (b) mGlu5 full-length and ECD alone (VFT and CRD) were labeled with the cysteine reactive
985   dye, monobromobimane. Though no signal was seen for ECD (dark grey), full-length (FL)
986   mGlu5 produced a bimane spectrum (light grey). This implies that mGlu5 TMs have
987   cysteine residues that are exposed to being labeled with bimane. n = 1 individual
988   experiment.

989   (c) WT and minimal cysteine (C691$^{4.30}$A and C681^{ICL2}A) constructs were labeled with
990   Atto488. Unlike WT, the minimal cysteine construct exhibits almost no background
991   labeling for the times tested.

992   (d) Fluorescence intensity at 464 nm for mGlu5 WT labeled with bimane (reading out on ICL2
993   conformation from Fig 3e) is plotted for the different ligand conditions. Though there is no
994   significant difference between Apo (light grey) and Quis (cyan), the addition of Quis and
995   CDPPB (dark green) showed a significant change. No further change was detected with the
996   addition of G_q to the Quis and CDPPB condition (yellow). The addition of MTEP resulted
997   in a significant decrease in fluorescence intensity (dark grey). Data represented as mean $\pm$
998   SD, ns = 0.5326, p= 0.0001***, p = 0.0026**, p < 0.0001****, unpaired t-test (two-tailed),
999   n = 3 individual experiments.

1000   (e) Bimane spectra of mGlu5 in nanodiscs labeled only at C681^{ICL2} (C691$^{4.30}$A construct).
1001   Unlike adding Quis (cyan) which resulted in no change in the spectrum, the addition of
1002   CDPPB alone (blue) or Quis and CDPPB (dark green) increases the fluorescence. On the
1003   other hand, LY341495 and MTEP (brown) cause a decrease in fluorescence. Data
1004   represented as mean $\pm$ SEM, n = 3 individual experiments.

1005   (f) Plotting the fluorescence intensity at 464 nm for bimane data in Extended Data Figure 10e
1006   shows a significant difference between CDPPB alone (blue), Quis and CDPPB (dark
1007   green), and LY341495 and MTEP (brown) compared to Apo (grey). Data represented as
1008   mean $\pm$ SEM, ns = 0.5713, p < 0.0001, p = 0.0257* (Apo vs CDPPB), p < 0.0160* (Apo
1009   vs Quis + CDPPB), unpaired t-test (two-tailed), n = 3 individual experiments.

1010   (g) Comparison of Quis-bound (cyan) and CDPPB, Quis-bound structures (dark green)
1011   showing changes in TM3 and TM4. Also shown is the position of residue C691$^{4.30}$ which
1012   is bimane labeled in the WT construct (Figure 3e, Extended Figure 10e).

1013

1014

1015

1016 **Extended Data Figure 11: smFRET fitting statistics and analysis**
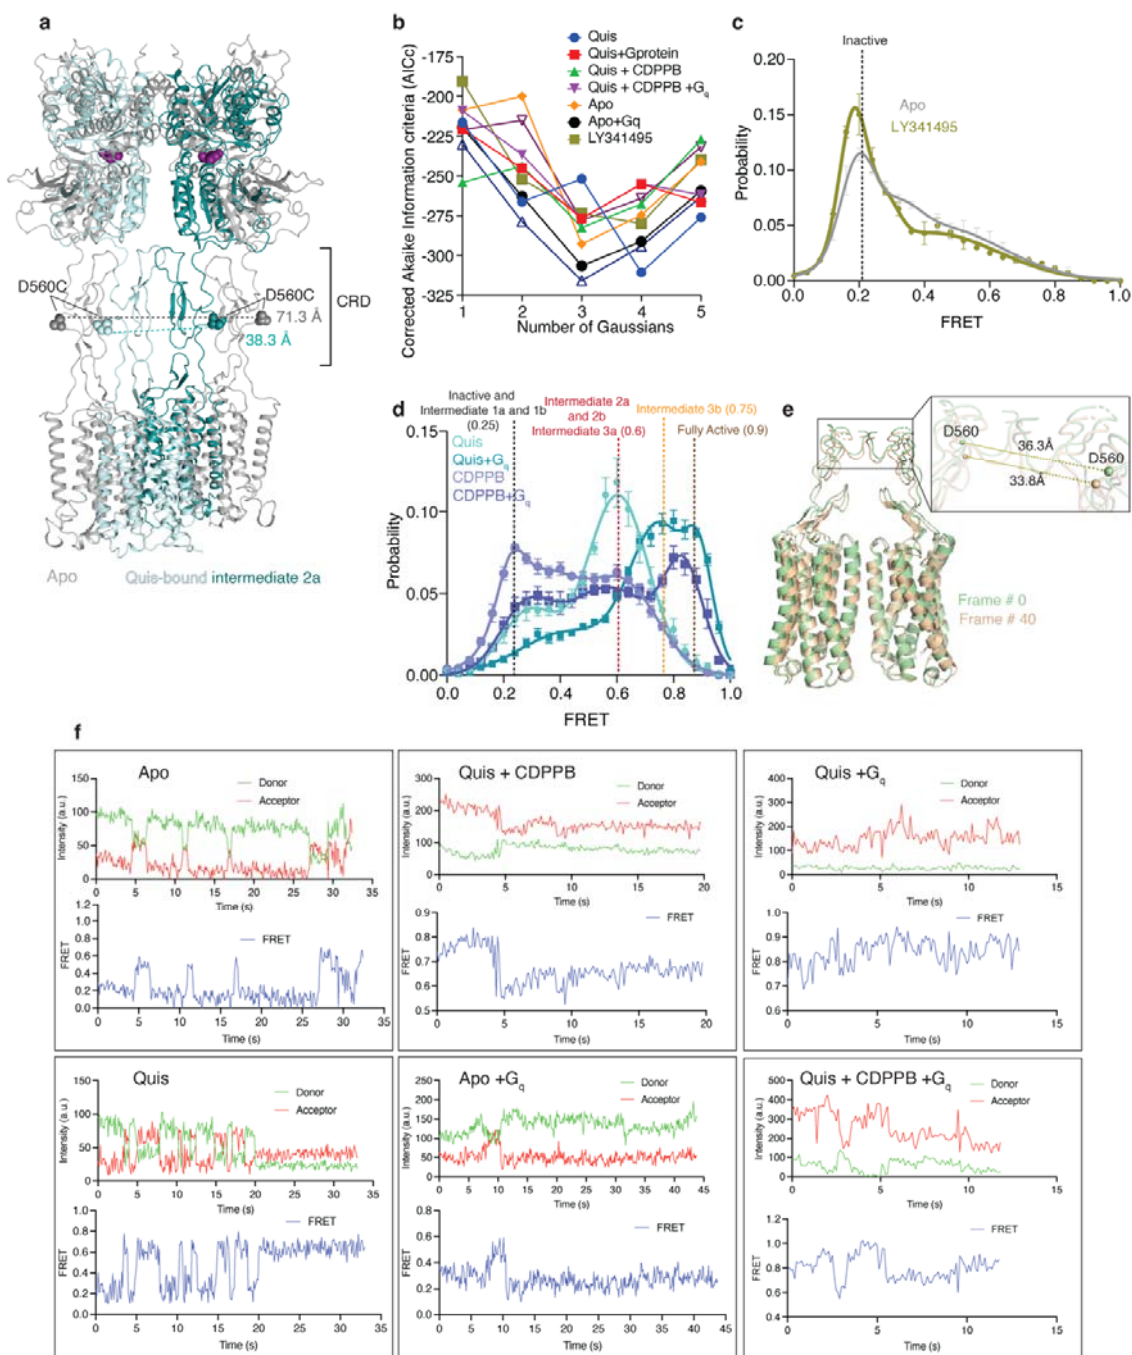

1017

1018 (a) Interdye distance between residue D560 in Apo (grey, 71.3 Å) and Quis-bound
1019 Intermediate 2a (36.3 Å). Both these distances correlated well with the observed FRET
1020 values (Figure 4b).

1021 (b) Plot of the Akaike information criterion (corrected for small sample size, AICc) values for
1022 analysis with 1 to 5 Gaussians fits for the smFRET data. The AICc values showed broad
1023 minima at 3 and 4 fits. 3 Gaussians were used to fit the data.

41

1024   (c) smFRET data showing the comparison of Apo (grey, N=319) and antagonist-bound mGlu5

1025   (brown, N=245).

1026   (d) The addition of CDPPB alone results in two FRET peaks, one at ~ 0.25, Intermediate 1b

1027   state, and the other at ~ 0.6, the Intermediate 2b state (slate, N=329). In the presence of

1028   Quis (teal), the same two FRET peaks are seen except with different relative proportions

1029   of the two states.

1030   (e) The addition of G_q to the Quis-alone sample shifts the population to the high FRET states,

1031   Intermediate 3b (~ 0.75) and Fully Active (~ 0.9) at the expense of the Intermediate 2a (~

1032   0.6) and Intermediate 1a (~ 0.25) peaks. For the CDPPB alone sample, the addition of G_q

1033   results in the appearance of a high FRET peak with a decrease, but not complete

1034   disappearance of the Intermediate 2b (~ 0.6) and Intermediate 1b (~ 0.25) peaks.

1035   (f) 3Dflex analysis of frames 0 and 40 showing a change in distance between the CRDs.

1036   (g) Example smFRET traces showing donor (green), and acceptor (red) intensity values as well

1037   as the calculated FRET values (blue) for a series of ligand conditions with and without G_q.
