protein translocation in vitro and enhanced the priming of antigen-specific T cells in vivo. Administering DC-targeted constructs with tumor antigens (Trp1/gp100) into mice bearing aggressive B16−F10 melanomas improved mouse outcomes when compared to free antigen, including suppressed tumor growth up to 58% at 16 days post tumor induction (*P* < 0.0001) and increased survival (*P* = 0.03). These studies demonstrate that harnessing DC-targeting anthrax proteins for cytosolic antigen delivery significantly enhances the immunogenicity and antitumor efficacy of cancer vaccines.

■ **INTRODUCTION**

Immunotherapies have gained significant traction over the past two decades for the treatment of cancer and infectious diseases.^{[1](#page-7-0)} Cancer vaccines are a particularly interesting class of immunotherapy, with the potential to provide either prophylactic or therapeutic effects through the stimulation of a patient's adaptive immune system.² After considerable efforts to develop anticancer immunizations, one therapeutic cancer vaccine is now FDA approved for treating refractory prostate cancer (Sipuleucel-T, Provenge). The advent of new cancer vaccine platforms, particularly when combined with immunecheckpoint blockade (ICB), not only offer the promise of treating additional cancer types but also provide long-term remission through immune-memory responses.^{[3](#page-7-0)} Nonetheless, successful elicitation of potent antitumor T cell responses after vaccination in humans, especially cytotoxic T cell responses, has thus far been challenging.^{[4](#page-7-0)} Vaccine platforms comprising proteins, peptides, nucleic acids (DNA or RNA), viral vectors, or immune cells offer new avenues to overcome these challenges and to provide more effective vaccines against cancer. $2,5,6$

Delivering target antigens into specific cell targets has emerged as a promising way to boost vaccine immunogenicity. Antigen presenting cells (APCs) provide ideal targets because these cells specialize in proteolytic processing and loading of antigens onto the peptide-binding groove of human leukocyte antigen (HLA) molecules (or major histocompatibility complex (MHC) molecules) for priming of T cells. Populations of APCs include dendritic cells (DCs), macrophages, and B cells, but DCs that participate in crosspresentation are considered the most efficient APCs for priming cytotoxic and immune-memory T cell responses.^{[7](#page-7-0)-[11](#page-8-0)} Developing immunotherapies that target cross-presenting DCs is challenging because closely related DC populations can exhibit opposing activity.^{[12](#page-8-0)} For example, $CD8⁺ DCs$ exhibit antigen cross-presentation and favor cytotoxic T lymphocyte (CTL) responses, while CD8[−] DCs favor non-CTL responses.^{[13,14](#page-8-0)}

Conventional type 1 dendritic cells (cDC1) efficient at antigen cross presentation are further identified by several unique receptors, including DEC-205, XCR1, and Clec9A.^{[15](#page-8-0)} In particular, expression of the chemokine XCR1 receptor was observed in CD8⁺ DCs, but not in T cells, B cells, NK cells, or

Received: May 19, 2023 Published: September 14, 2023

plasmacytoid DCs $(pDCs)$.^{[16](#page-8-0)} cDC1s are located in nonlymphoid tissues and in the marginal zone of the spleen and possess the ability to migrate in lymph nodes. While cDC2s activate CD4⁺ T cells, the cDC1 subset is the most effective for CD8+ T cell priming and for driving cell-mediated response via the cross presentation of exogenous and endogenous antigens to T cells. 17,18 17,18 17,18 17,18 17,18 In cancer patients, the presence of cDC1s in the $\,$ tumor microenvironment was correlated to a better survival and a higher response to anti-PD1 checkpoint blockade.^{[19,20](#page-8-0)} Therefore, cDC1s are considered to play a critical role in antitumor immunity and represent a particularly attractive target for the development of cancer vaccines. Only one ligand is known to bind the XCR1 receptor of cDC1s, which is the chemokine XCL1 that induces CD8⁺ DC migration and maturation[.16](#page-8-0) Previous efforts to develop vaccines based on targeting XCR1⁺ DCs include fusing antigens to XCL1 or a monoclonal XCR1-specific IgG, which have been shown to enhance priming of CTL responses.^{21–[23](#page-8-0)} Nonetheless, simply targeting the XCR1 receptor does not ensure uptake by intracellular compartments, which limits loading onto class I MHC molecules and reduces cross-presentation to T cells.^{[24,25](#page-8-0)}

Engineered bacterial toxins are an emergent delivery platform for shuttling therapeutic proteins into mammalian cells^{[26](#page-8-0)} and may offer an effective approach to maximize the cytosolic delivery of vaccine antigens.^{[27](#page-8-0),[28](#page-8-0)} In particular, the two nontoxic components of the anthrax delivery system, protective antigen (PA) and the N-terminus of lethal factor (LF_N) , have been shown to efficiently transport non-native cargo into the cytosol of cells, including more than 30 different peptides, proteins, and even small molecules.^{[29](#page-8-0)} Delivery through binding of the native anthrax receptor is readily achieved by coadministering PA and LF_N fused to the desired cargo. Changing the receptor specificity of PA can enable targeted, PA-mediated delivery into specific cell types. $30-34$ $30-34$ Achieving targeted delivery with the PA/LF_N system through non-native receptors requires development of fusion proteins with PA and a receptor-targeting protein while maintaining the function of both components. Developing a receptor-targeting PA fusion protein is a work-intensive process that has typically proved challenging. As a result, only a few receptor-targeting PA variants have been developed to date.

We recently introduced a generalizable workflow for incorporating receptor-targeting proteins into PA with a defined chemical bond.[35](#page-8-0) Essential to this workflow is a triple mutant PA, called mPAC, which contains two mutations that ablate binding to native anthrax receptors and a third mutation that provides a single cysteine residue for bioconjugation. Bioconjugation has allowed facile incorporation of mPAC onto targeting proteins, including antibodies, from diverse expression systems without hindering the preparation and native function of the conjugated components. The bioconjugation workflow has accelerated the development of new receptortargeting PA variants in our laboratory and is enabling in-depth preclinical studies on their therapeutic efficacy. Over time, we anticipate that the PA conjugates will be further developed as fusion proteins or used directly as conjugates in clinical settings.

Here, we combined mPAC with a single-chain variable fragment (scFv) that recognizes the XCR1 receptor (Figure $1A$).¹⁴ A peptide linker connects the two domains, enabling protein translocation with full-length mPAC (mPAC $_{83}$). The resulting scFv-mPAC (scFv-mPAC₈₃) translocates antigenic cargo fused with LF_N , in which the scFv targets XCR1-positive

Figure 1. Engineered anthrax proteins for targeted vaccine delivery into cross-presenting dendritic cells. (A) Designs of the engineered components: triple mutant protective antigen (mPAC), which enables side-chain bioconjugation and ablates binding to native anthrax receptors; single-chain variable fragment (scFv), which recognizes the XCR1 receptor; and a linker peptide (dotted line), which connects the scFv and mPAC. (B) Envisioned mechanism of translocation for scFv-mPAC (scFv-mPAC₈₃), which exhibits recognition of the XCR1 receptor, proteolytic cleavage (scFv-mPAC $_{63}$), oligomerization (scFv $mPAC$ ₇, and cytosolic delivery of the N-terminus of lethal factor (LF_N) with an appended antigen peptide (red).

cells and the mPAC exerts the conventional PA-mediated translocation mechanism (Figure 1B). This mechanism includes (1) scFv-mPAC₈₃ binding to the XCR1 receptor; (2) proteolytic cleavage of scFv-mPAC $_{83}$ into two components, scFv-mPAC₆₃ and mPAC₂₀; (3) scFv-mPAC₆₃ oligomerization into a heptameric prepore; (4) binding of three or four LF_N molecules to the scFv-mPAC $_{63}$ prepore; (5) endocytosis of the prepore complex, followed by the formation of an active transmembrane pore upon acidification of the endosome; and (6) PA-mediated translocation of the LF_{N} molecules into the cytosol. We anticipated that targeting XCR1 with the scFv would mimic functions of the native XCL1, by supporting induction of CD8⁺ DC migration and maturation.^{[16](#page-8-0)} Moreover, we anticipated that facilitating cytosolic antigen delivery into XCR1+ DCs would enhance the potency of the antigen cargo by providing access to the class I MHC antigen loading pathway. $24,25$ $24,25$ $24,25$ Also, we envisioned that this approach would limit off-target delivery into other cell types, requiring lower antigen amounts to achieve effective CTL responses.

Our studies show that anti-XCR1 scFv-mPAC selectively targets and delivers protein cargo into XCR1-positive cells. In vitro studies demonstrate that the translocation mechanism operates in a receptor-dependent and PA-mediated fashion. In vivo biodistribution studies highlight that scFv-mPAC accumulates in the lymph nodes and spleen and is taken up by antigen-presenting cells. In vivo vaccination studies show that antigen delivery utilizing $LF_N/scFv$ -mPAC enhances antigen-specific immunogenicity, inhibits tumor growth in tumor-bearing mice, and improves survival. These studies show promise for further therapeutic development, particularly for cancer immunotherapy.

■ **RESULTS**

Design and Preparation of a DC-Targeting Single-Chain Variable Fragment (scFv). Previously, we introduced a targeted protein delivery platform that contains anthrax protective antigen (PA_{83}) combined with a receptor-binding protein, including a full-length antibody or an $\text{scFv.}^{34,35}$ $\text{scFv.}^{34,35}$ $\text{scFv.}^{34,35}$ These constructs selectively target cancer cells and translocate toxic payloads fused to the N-terminus of lethal factor $(LF_N)^{34,35}$ $(LF_N)^{34,35}$ $(LF_N)^{34,35}$ Here, we aimed to engineer the anthrax proteins as a nontoxic delivery platform for cancer immunotherapy, enabled by targeting DCs and facilitating cytosolic delivery of antigen peptides. We developed a recombinant scFv fragment that recognizes the XCR1 receptor of DCs, which encodes the variable heavy (V_H) and light (V_L) chains from a parent anti-XCR1 monoclonal antibody (MARX10) (Figure 2A,B).^{[14,36](#page-8-0)} We incorporated a $(G_4S)_4$ spacer sequence between the V_H and V_L chains and a sortase-recognition tag to enable enzymatic ligation at the C-terminus (Figure 2B,C; [Table](https://pubs.acs.org/doi/suppl/10.1021/acscentsci.3c00625/suppl_file/oc3c00625_si_001.pdf) [S1](https://pubs.acs.org/doi/suppl/10.1021/acscentsci.3c00625/suppl_file/oc3c00625_si_001.pdf)). The scFv was prepared using recombinant expression in *E. coli*, followed by purification (Figure 2C) and characterization by LC-MS ([Figure](https://pubs.acs.org/doi/suppl/10.1021/acscentsci.3c00625/suppl_file/oc3c00625_si_001.pdf) S1). We also synthesized two peptides for the ligation called linker peptides 1 (Figure 2D). The peptides each contained three Gly residues for sortase ligation and two D-Leu residues to impart proteolytic stability. We varied the peptides at the N*^ε* -lysine position to contain an acetyl bromide (peptide 1a) and an AlexaFluor-647 (AF647) fluorophore (peptide 1b), followed by purification using RP-HPLC and characterization by LC-MS ([Figure](https://pubs.acs.org/doi/suppl/10.1021/acscentsci.3c00625/suppl_file/oc3c00625_si_001.pdf) S2).

Conjugating scFv to Protective Antigen. We conjugated the scFv to two previously reported PA mutants: (1) mPAC, which is a triple mutant PA[N682A, D683A, K563C] that permits bioconjugation but does not bind to native anthrax receptors; and (2) mPAC[F427A], which is a translocation-deficient homologue of mPAC that provides a negative control.^{[35](#page-8-0),[37,38](#page-8-0)} The mPAC and mPAC[F427A] were produced through recombinant expression in *E. coli*, followed by purification using anion-exchange (AEX) chromatography and characterization by LC-MS ([Figure](https://pubs.acs.org/doi/suppl/10.1021/acscentsci.3c00625/suppl_file/oc3c00625_si_001.pdf) $S3$).^{[39](#page-8-0)} Each protein was combined with anti-XCR1 scFv by a two-step bioconjugation procedure. [Figure](#page-3-0) 3A illustrates the procedure for mPAC (mPAC[F427A] is not shown). First, mPAC was incubated with peptide 1a (60 min, pH 8.5) to conjugate the peptide onto the Cys_{563} residue, which gave G_3 -mPAC [\(Figure](https://pubs.acs.org/doi/suppl/10.1021/acscentsci.3c00625/suppl_file/oc3c00625_si_001.pdf) [S4](https://pubs.acs.org/doi/suppl/10.1021/acscentsci.3c00625/suppl_file/oc3c00625_si_001.pdf)). Second, sortase-mediated ligation with the anti-XCR1 $scFv-LPSTG_2-H_6$ afforded the corresponding $scFv-mPAC$ construct ([Figure](https://pubs.acs.org/doi/suppl/10.1021/acscentsci.3c00625/suppl_file/oc3c00625_si_001.pdf) S5).^{[35](#page-8-0)} SDS-PAGE analysis showed purified fractions of scFv-mPAC after size-exclusion chromatography (SEC), followed by AEX chromatography [\(Figure](#page-3-0) 3B,C). The scFv-mPAC[F427A] was prepared in a similar fashion, which provided a translocation-deficient homologue as a negative control. We also prepared a AF647-labeled scFv to enable cellbinding studies. We used sortase-mediated ligation to combine scFv with peptide 1b, which was purified by SEC [\(Figure](#page-3-0) 3D).

Figure 2. Development of an anti-XCR1 scFv. (A, B) Design of the anti-XCR1 scFv, which encodes variable heavy (V_H) and light (V_L) chains from a parent anti-XCR1 IgG (MARX10). The scFv also contains a hydrophilic region $(G_4S)_4$ between the V_H and V_L chains and a sortase recognition tag $(LPSTG₂H₆)$ that enables protein ligation. (C) Coomassie-visualized SDS-PAGE gel of the recombinant scFv throughout the bacterial expression and purification steps: (1) whole cell lysate; (2) Ni NTA purification; (3) treatment with SUMO protease; and (4) ion-exchange (HiTrap Q HP) chromatography. (D) Linker peptide 1, which included 1a ($R = \alpha$ -bromoacetyl group) and 1b $(R = Alexa Fluor 647 (AF647)).$

Successful preparation of the scFv-AF647 construct was confirmed by LC-MS analysis [\(Figure](https://pubs.acs.org/doi/suppl/10.1021/acscentsci.3c00625/suppl_file/oc3c00625_si_001.pdf) S6).

Selective Protein Delivery into XCR1-Positive Cells. To establish scFv binding activity, we evaluated the recognition of the XCR1 receptor and the dependence on protein translocation. These experiments used two CHO cell lines: XCR1+ and XCR1[−]. We performed an initial recognition study by incubating the AF647-labeled scFv with CHO cells, followed by flow cytometry analysis. The plots show preferential recognition of the XCR1⁺ but not XCR1⁻ cells ([Figure](https://pubs.acs.org/doi/suppl/10.1021/acscentsci.3c00625/suppl_file/oc3c00625_si_001.pdf) S7).

Protein translocation studies were enabled by the fusion of LF_N to the A-chain of diphtheria toxin (LF_N -DTA), which provided a reporter protein to measure the translocation efficiency based on cell viability. DTA internalization into the cytosol inhibits the elongation factor 2 protein and, in turn, mRNA translation, which leads to cell death. However, DTA cannot internalize in the absence of the B-subunit and, therefore, is not toxic when administered alone. For establishing mechanisms of protein translocation, CHO cells are

Figure 3. Engineering a DC-targeting anthrax protective antigen. (A) Schematics for the protein ligation of $mPAC_{83}$ and an anti-XCR1 scFv: thiol-conjugation reaction with peptide 1a, followed by sortasemediated ligation with the scFv $(scFv-LPSTG₂-H₆)$. (B, C) Coomassie-visualized SDS-PAGE gels of fractions obtained from size-exclusion (HiLoad 16/600 Superdex 200) and anion-exchange (HiTrap Q HP) chromatography. (D) Schematic of the sortasemediated ligation reaction for scFv and peptide 1b.

conventionally treated with 20 nM PA and 10-fold serial dilutions of $LF_N-DTA.⁴⁰$

Here, we established that scFv-mPAC exerts translocation by a mechanism that is dependent on the scFv recognition of XCR1 receptors. These experiments also used XCR1⁺ and XCR1[−] CHO cells (Figure 4). The treatment conditions were based on conventional concentrations, in which cells were treated with 20 nM PA, scFv-mPAC, or scFv-mPAC[F427A] and with 10-fold serial dilutions of LF_N-DTA . After 72 h, native PA decreased viability for both XCR1[−] (EC₅₀ = 1.4 fM) and $XCR1^+$ (EC₅₀ = 1.3 fM) cell lines; scFv-mPAC decreased viability only for the XCR1⁺ (EC₅₀ = 9.9 pM) but not the XCR1[−] cells; and scFv-mPAC[F427A] did not decrease viability. Furthermore, treatment with LF_N-DTA alone, without translocation, did not decrease viability [\(Figure](https://pubs.acs.org/doi/suppl/10.1021/acscentsci.3c00625/suppl_file/oc3c00625_si_001.pdf) S8). The absence of toxicity from LF_N-DTA administered alone and when coadministered with scFv-mPAC[F427A] demonstrates that only translocated LF_N-DTA decreases viability, rather than the individual PA components.

The viability data from scFv-mPAC are consistent with an XCR1-dependent, PA-mediated translocation mechanism

Figure 4. ScFv-directed PA mediates selective protein translocation into XCR1-positive cells. Relative cell viability from the translocated A-chain of diphtheria toxin (DTA) into (A) XCR1⁺ and (B) XCR1⁻ CHO cells. Cells were incubated (72 h) with 10-fold serial dilutions of LF_N-DTA in the presence of 20 nM PA, scFv-mPAC, or scFvmPAC[F427A]. Relative viability (% viable cells) was determined by measuring luminescence from a Cell Titer-Glo assay; the viability was normalized to untreated cells. Data represent the mean of three replicate wells \pm the standard deviation (s.d.). Data are representative of two independent experiments.

(Figure 4A). This mechanism is dependent on CHO expression of XCR1 receptors, in which the potency is influenced by receptor expression and binding affinity. Although the potency for the XCR1-targeting PA is lower than that of native PA, this decrease in potency may reflect differences in receptor expression or binding affinity. We postulate that the plateau in viability is due to the presence of CHO cell populations that do not contain XCR1 and are therefore not susceptible to scFv binding. Moreover, the scFvmPAC does not decrease the viability of the XCR1[−] cells, which further infers that the absence of XCR1 precludes protein translocation (Figure 4B). These observations corroborate the scFv-mPAC proposed mechanisms of XCR1 targeting and receptor-mediated cytosolic delivery into XCR1 positive cells.

Biodistribution of XCR1-Targeting Constructs in Whole Mice. Anti-XCR1 scFv-mPAC trafficking and biodistribution were evaluated in healthy mice using whole-organ ex vivo near-infrared fluorescence (NIRF) imaging. The mPAC, scFv, and scFv-mPAC constructs were conjugated to commercial Alexa-Fluor 647 (AF647) dyes to give mPAC-AF647, scFv-AF647, and scFv-mPAC-AF647, respectively. AF647 (absorption: 650 nm, emission: 665 nm) is a wellcharacterized fluorochrome used for preclinical NIRF imaging in mice[.41](#page-8-0)[−][43](#page-9-0) NIRF imaging was performed at 2, 24, and 48 h

post subcutaneous (s.c.) injection with 1 nmol of scFv-AF647, mPAC-AF647, scFv-mPAC-AF647 in C57Bl/6J mice (Figure 5A, B). ScFv-AF647 distributed in a few hours with residual signal remaining after 24 h, accumulating mainly in the inguinal and axillary lymph nodes and spleen. mPAC-AF647 cleared mainly through the liver and was detected for up to 48 h in the inguinal and axillary lymph nodes. The scFv-mPAC-AF647 showed lower uptake in the liver, indicating reduced off-target uptake compared to mPAC-AF647 administered alone and significantly higher trafficking to the inguinal lymph nodes at 2 h postinjection. Furthermore, the uptake of scFvmPAC-AF647 in the spleen was higher at 24 and 48 h compared to mPAC-AF647 and scFv-AF647 administered alone. Toxicity is a major concern for drug development and these findings suggest that scFv-mPAC has a more favorable pharmacokinetic profile than mPAC alone, with a lower potential for adverse toxicity in the liver.

We also evaluated the single-cell fluorescence of AF647 positive splenocytes at 2 h post s.c. injection using flow cytometry (Figure 5C). These studies showed that a significant fraction of AF647-positive cDC1s were detected after the s.c. injection of scFv (28 \pm 1.5%) and scFv-mPAC (24 \pm 2.1%) compared to the control vehicles $(3 \pm 1.4\%)$. In addition, the AF647-positive macrophages were also significantly higher after scFv (37 \pm 1.2%) and scFv-mPAC (16 \pm 1.7%) injections compared to the controls ($6 \pm 1.1\%$). Nonetheless, the AF647positive T and B cells remained similar in all groups. These findings confirm that anti-XCR1 scFv distributes through mouse lymph nodes and spleen and promotes uptake by CD8+ DC.

The specificity of anti-XCR1 scFv was further evaluated with murine splenocytes ex vivo. Single-cell suspensions of murine splenocytes (C57BL/6) were incubated with the scFv, followed by antibody staining and flow cytometry analysis ([Figures](https://pubs.acs.org/doi/suppl/10.1021/acscentsci.3c00625/suppl_file/oc3c00625_si_001.pdf) S9−S11). The data show that the scFv preferentially recognizes $CDS⁺ DCs$; the data also show nonspecific uptake by medullary macrophages, which are known for phagocytosis of protein antigens.

Cytosolic Delivery of Antigens into Dendritic Cells Enhances Antigen Immunogenicity. PA/LF_N-mediated antigen delivery confers antigen-specific immunity by a mechanism consistent with MHC class I presentation and the priming of $CD8⁺$ T cells. We evaluated this immune response in mice using the established epitope of ovalbumin: SIINFEKL $(OVA_{257–264})^{45,46}$ $(OVA_{257–264})^{45,46}$ $(OVA_{257–264})^{45,46}$ $(OVA_{257–264})^{45,46}$ $(OVA_{257–264})^{45,46}$ The vaccine comprised a synthetic long epitope peptide: OVA_{257−270}. This peptide was incorporated into LF_N to give LF_N -OVA₂₅₇₋₂₇₀ [\(Table](https://pubs.acs.org/doi/suppl/10.1021/acscentsci.3c00625/suppl_file/oc3c00625_si_001.pdf) S2; [Figure](https://pubs.acs.org/doi/suppl/10.1021/acscentsci.3c00625/suppl_file/oc3c00625_si_001.pdf) S12) and was s.c. administered to mice with mPAC, PA, or scFv-mPAC ([Figure](#page-5-0) 6A). The c-di-GMP adjuvant, an activator of the STING signaling pathway, was coadministered with the vaccine to enhance the immune response.^{[47](#page-9-0)–[49](#page-9-0)} Mice were sacrificed 7 days after receiving the boost to evaluate IFN*γ* release from splenocyte cells, enabling quantitation of antigen-specific CTL priming ([Figure](#page-5-0) 6B).^{[50](#page-9-0)},^{[51](#page-9-0)} Enzyme-linked immunosorbent spot analysis (ELISpot), after stimulation with the SIINFEKL epitope (Table S3; [Figure](https://pubs.acs.org/doi/suppl/10.1021/acscentsci.3c00625/suppl_file/oc3c00625_si_001.pdf) S13), showed that LFN-OVA252[−]²⁷⁰ induced a release of proinflammatory IFN-*γ* cytokines in all groups. When the $LF_N-OVA_{252–270}$ vaccine was injected with the anti-XCR1 scFv-mPAC, the immunogenicity increased by ∼32% (436 ± 49 colonies) compared to PA (299 ± 53 colonies) and ∼67% to mPAC (147 ± 38 colonies). This study highlights that targeting XCR1 significantly enhances CTL response in immunocompetent mice.

Figure 5. Targeting XCR1 facilitates trafficking to lymph nodes and antigen-presenting cells. (A,C) Time-course analysis of AF647 signal in mouse organs: two mice per time point for mPAC and scFv; one mouse per time point for scFv-mPAC. Mice were treated with 1 nmol of an AF647-labeled construct: mPAC, anti-XCR1 scFv, or anti-XCR1 scFv-mPAC. The constructs were subcutaneously (sc) administered over two equal volume injections, one on each side of the tail base (*n* = 5 mice per group for mPAC and scFv; *n* = 3 mice for scFv-mPAC). (A) Representative images obtained after 2 h using an in vivo imaging system (IVIS), showing AF647 signal from resected lymph nodes (inguinal and axillary), spleen, and liver. Data represent the mean of whole-organ radiant efficiency \pm s.d. (B) Quantification of the AF647 signal after 2, 24, and 48 h. (C) Flow cytometry analysis of the AF647 signal after 2 h in single-cell splenocyte populations, including CD8⁺ dendritic cells (CD11c⁺CD8⁺), medullary macrophages (CD11b⁺F4/ 80+), and T and B cells (CD3⁺ B220⁺). Data represent the mean of AF647+ cells \pm s.d. All data are representative of two independent experiments.

We also evaluated the mechanism of immunity with additional experiments. MHC class I presentation was evaluated by the treatment of murine DC2.4 cells with PA/

Figure 6. XCR1-targeted intracellular delivery outperforms nontargeted constructs. (A) Mice were s.c. vaccinated with LF_N-OVA (30 pmol, OVA252−270) and c-di-GMP (25 *μ*g), which were coadministered with mPAC, PA, or scFv-mPAC (6 pmol). (B) IFN-*γ* enzymelinked immunosorbent spot (ELISpot) data are shown from 7 days after the boost (mean \pm SEM; $n = 10$ mice per group). Statistical significance was calculated using a one-way ANOVA with the Fisher's Least Significant Difference test. Data are compiled from two independent experiments.

 $LF_N-OVA_{257–264}$ [\(Table](https://pubs.acs.org/doi/suppl/10.1021/acscentsci.3c00625/suppl_file/oc3c00625_si_001.pdf) S2), followed by flow cytometry analysis of the presented epitope. 52 The data show prominent MHC class I presentation of the SIINFEKL peptide after 6 h, which decreases after 24 h [\(Figure](https://pubs.acs.org/doi/suppl/10.1021/acscentsci.3c00625/suppl_file/oc3c00625_si_001.pdf) S14). Antigen-specific CTL responses were evaluated by MHC tetramer and intracellular cytokine staining (ICS). The data show priming of OVAspecific T cells from the combined treatment with c-di-GMP and $PA/LF_N-CVA_{257-264}$ but not from the monotherapies with PA or LF_N -OVA₂₅₇₋₂₆₄ alone ([Figure](https://pubs.acs.org/doi/suppl/10.1021/acscentsci.3c00625/suppl_file/oc3c00625_si_001.pdf) S15). The data show a measurable persistence of this CTL response after four vaccinations ([Figure](https://pubs.acs.org/doi/suppl/10.1021/acscentsci.3c00625/suppl_file/oc3c00625_si_001.pdf) S16), which steadily decreases after each dose due to potential neutralizing antibodies responses that disable the carrier proteins (i.e., PA and LF_N). These studies further establish that the CTL response is antigenspecific and persists after repeat injections.

LF_N-Trp1-gp100/scFv-mPAC Vaccine Is Effective in **Mice Bearing B16**−**F10 Tumors.** B16−F10 is a highly aggressive murine cancer model and is widely used for either subcutaneous or metastatic models of melanoma.^{[53](#page-9-0)-[55](#page-9-0)} B16 tumors are known to downregulate class I MHC to limit recognition by cytotoxic T cells.^{[56,57](#page-9-0)} We chose to target two cell-studied tumor associated antigens expressed by B16 tumors, Trp1 and $gp100$.^{[58](#page-9-0)-[60](#page-9-0)}

In the present study, we aimed to evaluate the peptide antigen Trp1-gp100 (Table S2; [Figure](https://pubs.acs.org/doi/suppl/10.1021/acscentsci.3c00625/suppl_file/oc3c00625_si_001.pdf) S17) when conjugated to LF_N ([Figure](https://pubs.acs.org/doi/suppl/10.1021/acscentsci.3c00625/suppl_file/oc3c00625_si_001.pdf) S18), followed by translocation into DCs. We envisioned that the anti-XCR1 scFv-mPAC would facilitate DC maturation and recruit $CDS⁺ T$ cells when compared with the unconjugated antigens (Table S3; [Figures](https://pubs.acs.org/doi/suppl/10.1021/acscentsci.3c00625/suppl_file/oc3c00625_si_001.pdf) S19, S20). We hypothesized the dual activity of the melanoma antigens would increase the immunogenic response against B16−F10 tumors. Given the aggressive nature of the B16 model, we combined vaccination with anti-PD-1 checkpoint blockade to further amplify antitumor activity. The efficacy of the LF_N-Trp1 gp100/scFv-mPAC vaccine was assessed in C57Bl/6J immunocompetent mice bearing subcutaneous B16−F10 tumors [\(Figure](#page-6-0) 7A). Tumor growth was monitored over the entire experiment ([Figure](#page-6-0) 7B). On days 13 and 16 post-tumor induction, significant inhibition of tumor growth was observed in the LF_N -Trp1-gp100/scFv-mPAC group but not in the naïve group or the Trp1 + gp100 group. After day 16, the mice vaccinated with LF_N -Trp1-gp100/scFv-mPAC showed inhibited tumor growth, compared to the controls, until the end of the experiment $(p < 0.0001)$.

Tumor growth curves upon treatment with LF_N-Trp1 gp100/scFv-mPAC show a plateau from day 10 to 20, with tumor growth returning to a similar rate as the control groups approximately after day 20 ([Figure](#page-6-0) 7C). No significant vaccinerelated toxicity was noticed after the four rounds of vaccination, as neither loss of appetite, loss of weight, reduction of socialization, nor change in behavior was observed ([Figure](#page-6-0) 7D). Kaplan–Meier analysis indicates that the LF_N -Trp1-gp100/scFv-mPAC vaccine significantly prolongs the survival of mice, with a median survival of 26 days, versus 18 days for the naive $(P < 0.0001)$ and 20 days for the Trp1 + $gp100 (P = 0.03)$ groups ([Figure](#page-6-0) 7E). Both tumor growth and survival data highlight that B16−F10 cancer progression was significantly delayed from about a week after vaccination with $LF_N-Trp1-gp100/scFv-mPAC$.

Nonetheless, treatment with $LF_N-Trp1-gp100/scFv-mPAC$ showed wide variation in tumor growth and relapse after day 20, indicating an incomplete response. Potential resistance to the PA/LF_N carrier proteins may explain the tumor relapse after the third vaccine injection. Similar observations have been made in a recent study, following vaccination of mice bearing B16−F10 tumors with TTR-Trp1-gp100 peptides.^{[61](#page-9-0)} Although anti-PD1 antibodies were administered concomitantly with the vaccine, these treatments may have been insufficient to obtain complete inhibition of ICB as some animals may have become unresponsive due to potential mutations occurring in the IFN*γ*-JAK-STAT signaling pathway.[62](#page-9-0)−[64](#page-9-0) While the coadministration of the STING analog adjuvant c-di-GMP should increase the sensitivity for anti-PD-1 antibodies, $47-49$ $47-49$ $47-49$ melanomabearing mice can undertake adaptive ICB resistance. Indeed, B16−F10 tumors are described to have genetic or acquired resistance mechanisms to vaccines and drugs, and are therefore challenging to treat, thereby explaining that no animal was cured during the therapy study.

After day 10, tumors in the control groups showed hyperpigmentation, followed by necrosis, due to postinflammatory overaccumulation of eumelanin. However, in the LF_N -Trp1-gp100/scFv-mPAC group, we observed that, even after day 20, the tumors were non- or little-pigmented, and, after the fourth vaccine injection, there was a loss of pigmentation and change in tumor phenotype [\(Figure](https://pubs.acs.org/doi/suppl/10.1021/acscentsci.3c00625/suppl_file/oc3c00625_si_001.pdf) S21). Melanogenesis is regulated by an array of inflammation signals, including

Figure 7. Vaccine efficacy for cancer immunotherapy. (A) Immunization timeline. Mice (F, C57Bl/6, $n = 10$ per group) were s.c. inoculated with 3 × 105 B16−F10 cells (day 0). On days 4, 10, 16, and 22, all mice were intraperitoneally (i.p.) injected with anti-PD1 antibody (200 *μ*g) and were s.c. vaccinated (vacc) with c-di-GMP (25 μg) combined with either Trp1 + gp100 peptides (50 pmol each) or LF_N-Trp1-gp100 (50 pmol) + scFvmPAC (10 pmol). (B) Mean tumor growth $\rm (mm^2)$ per group. Data represent the mean tumor growth \pm SEM. Statistical significance was calculated using two-way ANOVA with Tukey test (main effect only model) with multiple mean comparisons on the entire curves, * *P* < 0.05; ** *P* < 0.005; *** *P* < 0.001; and **** *P* < 0.0001. (C) Tumor growth plots for the individual mice over the entire experiment. (D) Body weight. Data represent the mean + SEM (E) Kaplan−Meier percent of survival curves. Statistical significance was calculated using the log-rank Mantel−Cox test. Median survival: 18 days in the naïve group, 20 days in the Trp1 + gp100 group, and 26 days in the LF_N-Trp1-gp100 + scFv-mPAC group.

cytokines, interleukins, tumor necrosis factor (TNF), or prostaglandin E2, among others.⁶⁶ In B16−F10 tumors, the production of melanin can be inhibited by IFN-*γ* which blocks the maturation of the melanosome and upregulates the phosphorylation of the STAT1 signaling pathway, both resulting in cell apoptosis.[67,68](#page-9-0) The hypopigmentation of tumors in the vaccine group is thereby consistent with the abrogation of tumor growth and improvement of survival. These outcomes suggest that the dual translocation of Trp1/ gp100 into DCs using the LF_N /scFv-mPAC vaccine induced overexpression of IFN-*γ* and therefore induced a strong reduction in tumor growth.

■ **DISCUSSION**

Therapeutic cancer vaccines rely on administering large amounts of specific tumor antigens to activate DCs and induce a durable CTL response.^{[2](#page-7-0)} Despite considerable efforts, the first generations of therapeutic cancer vaccines failed to elicit sufficient T cell activation and long-lasting immunity, mainly due to insufficient delivery and/or the choice of tumorspecific antigens. $69-71$ $69-71$ $69-71$ Subsequent cancer vaccine research has focused on improving the nature and selection of target antigens, including through the identification of immunogenic tumor mutations and the assessment of epitope binding affinity to HLA alleles.^{[72](#page-10-0)-[74](#page-10-0)} Tumor antigens that are unique to each patient, called neoantigens, have also motivated the develop-ment of personalized cancer vaccines.^{[75](#page-10-0)} A major challenge for developing next-generation therapeutic vaccines is engineering more specific and effective delivery platforms of these tumor antigens.

In previous studies, we engineered cancer-targeting mPAC constructs to translocate cytotoxic payloads. $34,76$ $34,76$ Here, we developed a DC-targeting delivery system for immunogenic epitopes. The delivery system comprises an anti-XCR1 scFv conjugated to mPAC, which is a nontoxic triple mutant anthrax protective antigen protein. Administering the scFv-mPAC with an antigen-conjugated LF_N activated in vivo immune responses through the recruitment of $CD8⁺$ T cells and demonstrates that the scFv-mPAC/LF_N system targets DCs with tumorspecific antigens. In mice, s.c. administration of the DCtargeting platform showed trafficking through the lymphatic system and a significant activation of $CD8⁺$ T cells in the spleen. Moreover, the administration of scFv-mPAC with an LF_N -conjugated antigen OVA_{252−270} increased the immunogenicity in splenocytes by 32% compared to the nontargeting of XCR1 antigen.

Recently, a T cell engager medication comprising a bispecific fusion anti-CD3 protein targeting gp100 membrane antigen (Tebentafusp) has shown potent antitumor response with significant improvement of overall survival at 1 year in patients with metastatic refractory melanoma^{[60](#page-9-0)[,77](#page-10-0)} and HLA-A*02:01-positive uveal melanoma patients^{[78](#page-10-0)} for which it gained FDA approval in 2022. We have therefore selected gp100, but also Trp1 tumor-specific antigens, for the construction of a dual LF_N conjugate and assessed DCs targeting efficacy in an aggressive melanoma model. Administering scFv-mPAC in combination with $LF_N-Trp1-gp100$ in B16–F10 murine melanoma demonstrated a significant abrogation of tumor growth and tumor depigmentation, which was accompanied by a significant extension of survival (26 days compared to 18 and 20 days for the controls).

■ **CONCLUSION**

The studies described in this paper embody a proof-of-concept cancer vaccine that utilizes the anthrax PA/LF_N translocation mechanism for targeting and loading cDC1s with tumor antigens to prime $CDS⁺ T$ cells. Our studies show that $PA/$ LF_N can be engineered to target $XCR1⁺ DCs$, translocate antigenic cargo, and enhance priming of antigen-specific CTL responses. The $scFv-mPAC/LF_N-Trp1-gp100$ vaccination against B16−F10 melanoma demonstrates that this platform inhibits tumor cell growth, even of aggressive cancers. Our results validate the importance of developing cancer immunotherapies that target DCs. We are currently investigating additional immunotherapy platforms that target DCs and will report our findings in due course.
