

# IRGM1 supports host defense against intracellular bacteria through suppression of type I interferon in mice

**To the Editor:** IFN- $\gamma$  enhances cell-autonomous host defense by inducing several families of antimicrobial target genes, including immunity-related GTPases (IRGs). Animals deficient in IRGM1, the best-studied IRG, succumb to numerous bacterial and protozoal infections in a manner that nearly phenocopies that of IFN- $\gamma$ -null mice (1). This infection susceptibility has been attributed to the cell-intrinsic role of IRGM1 in xenophagy and targeting of pathogen-containing vacuoles (1).

Recently, we reported that *Irgm1*<sup>-/-</sup> mice spontaneously produce excess type I IFN (IFN-I) (2). Although IFN-I is protective against virus, it can compromise antibacterial host defense (3). We hypothesized that IFN-I, rather than defective cell-intrinsic defenses, drives the susceptibility of *Irgm1*<sup>-/-</sup> mice to bacteria. Consistent with this, we found that *Irgm1*<sup>-/-</sup> mice succumbed to *Mycobacterium tuberculosis* and *Listeria monocytogenes*, as previously reported (1), but *Irgm1*<sup>-/-</sup> mice lacking the IFN-I receptor, IFNAR1 (i.e., *Irgm1*<sup>-/-</sup>*Ifnar*<sup>-/-</sup> mice), were resistant (Figure 1A). Similarly, the increased pathogen burden in *Irgm1*<sup>-/-</sup> mice following infection with *Salmonella typhimurium* was normalized in *Irgm1*<sup>-/-</sup>*Ifnar*<sup>-/-</sup> mice (Figure 1A). By contrast, during infection with *Toxoplasma gondii*, a pathogen for which IFN-I is host protective (4), *Irgm1*<sup>-/-</sup> mice had reduced survival, and this was not rescued in *Irgm1*<sup>-/-</sup>*Ifnar*<sup>-/-</sup> animals (Supplemental Figure 1A; supplemental material, including the Supplemental Methods, available online with this article; <https://doi.org/10.1172/JCI171982DS1>).

To investigate IFN-I's mechanism of compromising host defense in *Irgm1*<sup>-/-</sup> mice, we pursued the *L. monocytogenes* infection model. After infection, *Irgm1*<sup>-/-</sup> mice had elevated biomarkers of organ damage in sera (Supplemental Figure 1B) and increased inflammation and necrosis in livers and spleens (Supplemental Figure 1, C-E), phenotypes that were rescued in *Irgm1*<sup>-/-</sup>*Ifnar*<sup>-/-</sup> mice. Increased cell death in *Irgm1*<sup>-/-</sup> livers and spleens was dependent on IFN-I signaling (Figure 1, B and C, and Supplemental Figure 1, F and G). Compared with that in WT and *Irgm1*<sup>-/-</sup>*Ifnar*<sup>-/-</sup> organs, there was increased *L. monocytogenes* growth in *Irgm1*<sup>-/-</sup> organs (Supplemental Figure 1, H-J). Increased growth was seen by 4 hours after infection in the peritoneum (Figure 1D), the site of *L. monocytogenes* inoculation in our model, indicating that IFN-I suppresses clearance of *L. monocytogenes* upon initial encounter. Indeed, *Irgm1*<sup>-/-</sup> F4/80<sup>hi</sup> peritoneal macrophages internalized *L. monocytogenes* normally in vitro (Supplemental Figure 2A) but had reduced killing capacity (Figure 1E). This was associated with decreased lysosomal delivery of *L. monocytogenes* (Figure 1F and Supplemental Figure 2B), despite normal lysosomal mass (Supplemental Figure 2C) and pH (data not shown) in *Irgm1*<sup>-/-</sup> macrophages. *L. monocytogenes*-challenged *Irgm1*<sup>-/-</sup> F4/80<sup>hi</sup> peritoneal macrophages also had higher expression levels of STAT1, STAT2, (Y701)-PO<sub>4</sub>-STAT1, and (Y689)-PO<sub>4</sub>-STAT2 than their WT and

*Irgm1*<sup>-/-</sup>*Ifnar*<sup>-/-</sup> counterparts (data not shown). In vivo, 4 hours after infection by GFP-expressing *L. monocytogenes*, only *Irgm1*<sup>-/-</sup> F4/80<sup>hi</sup> macrophages showed increased bacterial load (Figure 1G and Supplemental Figure 2D).

Given that IFN-I may induce cell death (3), we examined peritoneal myeloid cells for viability (Supplemental Figure 2E). Lytic death was increased in the *Irgm1*<sup>-/-</sup> peritoneum on days 1 and 3 after infection and was IFN-I-dependent (Supplemental Figure 3A). Fewer neutrophils were recruited by 4 hours after *L. monocytogenes* infection to *Irgm1*<sup>-/-</sup> peritonea, but neutrophil accumulation increased dramatically after 24 hours in an IFN-I-dependent manner (Figure 1H), and increased citrullinated histones, a marker of lytic neutrophil death by NETosis, were detected on day 3 (Supplemental Figure 3B). Increased IFN-I-dependent lytic death was also observed among F4/80<sup>hi</sup> macrophages (Supplemental Figure 3A), perhaps explaining their depletion 24 hours after infection (Figure 1, I and J). Notably, increased staining of phosphorylated mixed lineage kinase domain-like pseudokinase, a necroptosis effector, was observed only in *Irgm1*<sup>-/-</sup> macrophages (Supplemental Figure 3, C and D). Thus, IFN-I promotes multiple modes of proinflammatory lytic cell death in *Irgm1*<sup>-/-</sup> mice. Accordingly, *Irgm1*<sup>-/-</sup> peritoneal fluid exhibited an IFN-I-dependent increase in lactate dehydrogenase activity and proinflammatory cytokines (Supplemental Figure 3, E and F).

During peritonitis, death of resident macrophages leads to recruitment and reprogramming of Ly6C<sup>hi</sup>F4/80<sup>lo</sup> monocytes into Ly6C<sup>+</sup>F4/80<sup>hi</sup> macrophages, often through an MHCII<sup>+</sup>F4/80<sup>lo/int</sup> intermediate (5). We observed emergence of a small F4/80<sup>+</sup> population on day 3 after *L. monocytogenes* infection (Supplemental Figure 2E). Unlike their WT, *Ifnar*<sup>-/-</sup>, and *Irgm1*<sup>-/-</sup>*Ifnar*<sup>-/-</sup> counterparts, all CD11b<sup>+</sup>F4/80<sup>hi</sup> macrophages in the *Irgm1*<sup>-/-</sup> peritoneum at day 3 after *L. monocytogenes* infection retained high Ly6C and did not express TIM4 (Supplemental Figure 4, A and B), a maturity marker of peritoneal macrophages (5). The CD11b<sup>+</sup>F4/80<sup>lo</sup> population in *Irgm1*<sup>-/-</sup> animals remained Ly6C<sup>hi</sup> at day 3 and lacked a MHCII<sup>+</sup> subpopulation (Supplemental Figure 4C). The receptor for colony-stimulating factor-1 (CD115), which is critical for survival and differentiation of monocytes, was repressed in *Irgm1*<sup>-/-</sup> Ly6C<sup>hi</sup> cells in an IFN-I-dependent manner (Supplemental Figure 4C). Ly6C<sup>hi</sup> monocytes were also elevated in *Irgm1*<sup>-/-</sup> blood and showed reduced CD115 and MHCII (Supplemental Figure 4E). These results suggest that excess IFN-I in *Irgm1*<sup>-/-</sup> mice impairs maturation of inflammatory Ly6C<sup>hi</sup> monocytes into macrophages, possibly by repressing CD115.

To specifically examine myeloid IFN-I signaling, we infected *Irgm1*<sup>-/-</sup> mice lacking IFNAR1 solely in myeloid cells (*Irgm1*<sup>-/-</sup>*LysM*:*Cre*<sup>+</sup>*Ifnar*<sup>Fx/Fx</sup> mice). These mice showed decreased necrotic death of peritoneal myeloid cells, partial rescue of CD115 in

**Figure 1. IFN-I induces susceptibility to bacterial infection in *Irgm1*<sup>-/-</sup> mice.** (A) Survival curves after infection with *M. tuberculosis* (n = 7–10) and *L. monocytogenes* (n = 4–5). Spleen CFU on day 21 after *S. typhimurium* infection (n = 4–9). (B) Liver on day 3 after *L. monocytogenes* infection stained for TUNEL and DAPI. Scale bar: 200 μm. (C) Quantification of TUNEL<sup>+</sup> foci (n = 3). (D) Peritoneal lavage CFU at 4 hours, day 1, and day 3 after *L. monocytogenes* (n = 4–8). (E) Isolated F4/80<sup>hi</sup> peritoneal macrophages exposed to *L. monocytogenes* were permeabilized for CFU count after 24 hours. (F) Macrophages were stained for *L. monocytogenes* and lysosome (LAMP1) at 6 hours and quantified for volumetric pixels of *L. monocytogenes* that were LAMP1<sup>+</sup> (n = 32 images). (G) Percentage GFP<sup>+</sup> after 4-hour infection by GFP-tagged *L. monocytogenes* (n = 9–10). (H) Neutrophil and (I) F4/80<sup>hi</sup> tissue macrophage numbers in infected peritoneal lavage (n = 7–11). (J) Representative plot showing depletion of CD11b<sup>+</sup>F4/80<sup>hi</sup> macrophages at 24 hours. (K) CFU in peritoneal cavity (PerC), liver, and spleen on day 3 after *L. monocytogenes* (n = 5–8). Data are shown as the mean ± SEM. #P < 0.08, \*P < 0.05, \*\*P < 0.01, \*\*\*P < 0.001, and \*\*\*\*P < 0.0001 (1-way ANOVA with Tukey’s adjustment for A and C–I or Student’s t test for K).

CD11b<sup>+</sup>F4/80<sup>lo</sup>Ly6C<sup>-</sup> cells (Supplemental Figure 4, F and G), and reduced bacterial burden (Figure 1K) compared with controls, indicating that myeloid IFN-I signaling compromises myeloid cell fate and host defense in *Irgm1*<sup>-/-</sup> mice.

Our findings challenge the long-prevailing paradigm that IRGM1 serves as an IFN-γ-induced cell-autonomous host defense effector (1) and suggest instead that IRGM1 supports host defense by preventing excess autocrine and/or paracrine IFN-I from compromising myeloid cell fate and function. Future studies will be required to distinguish autocrine versus paracrine mechanisms.
