# **Abstract**

We review current methods and bioinformatics tools for the text complexity estimates (information and entropy measures). The search DNA regions with extreme statistical characteristics such as low complexity regions are important for biophysical models of chromosome function and gene transcription regulation in genome scale. We discuss the complexity profling for segmentation and delineation of genome sequences, search for genome repeats and transposable elements, and applications to next-generation sequencing reads. We review the complexity methods and new applications felds: analysis of mutation hotspots loci, analysis of short sequencing reads with quality control, and alignment-free genome comparisons. The algorithms implementing various numerical measures of text complexity estimates including combinatorial and linguistic measures have been developed before genome sequencing era. The series of tools to estimate sequence complexity use compression approaches, mainly by modifcation of Lempel–Ziv compression. Most of the tools are available online providing large-scale service for whole genome analysis. Novel machine learning applications for classifcation of complete genome sequences also include sequence compression and complexity algorithms. We present comparison of the complexity methods on the diferent sequence sets, the applications for gene transcription regulatory regions analysis. Furthermore, we discuss approaches and application of sequence complexity for proteins. The complexity measures for amino acid sequences could be calculated by the same entropy and compression-based algorithms. But the functional and evolutionary roles of low complexity regions in protein have specifc features difering from DNA. The tools for protein sequence complexity aimed for protein structural constraints. It was shown that low complexity regions in protein sequences are conservative in evolution and have important biological and structural functions. Finally, we summarize recent fndings in large scale genome complexity comparison and applications for coronavirus genome analysis.

# <span id="page-0-0"></span>**Introduction**

We rereview current works and bioinformatics tools for DNA text complexity estimates with next applications in short sequence analysis, complete genome studies, and protein annotations. The methods for complexity estimates have been realized in 1990s before the Human genome project (Trifonov [1990](#page-11-0); Gusev et al. [1991](#page-8-0); Román-Roldán et al. [1998](#page-10-0)). Information measures and entropies estimates serve as background for biophysical models of genome structure and evolution (Sadovsky et al. [2008\)](#page-10-1). The theory of overlapping genetic codes (protein coding triplets, RNA structure signal, nucleosome positioning codes, and topological chromosome codes) started from the works by E.N.Trifonov (Trifonov [1989](#page-11-1), [1990\)](#page-11-0) relies to numerical sequence complexity.

With development of the high-throughput sequencing technologies the complexity analysis tools evolved from simple algorithm realization to advanced online programs, large scale genome data processing software (Orlov and Potapov [2004](#page-10-2); Kryukov et al. [2020](#page-9-0); Agenis-Nevers et al. [2021;](#page-7-0) Karakatsanis et al. [2021;](#page-9-1) Zimnyakov et al. [2023;](#page-11-2) Bello et al. [2023\)](#page-8-1).

In the next sections of this "[Introduction,](#page-0-0)" we will discuss applications of the complexity profling to segmentation and delineation of genome sequences, search for genome repeats and transposable elements, and next-generation sequencing reads. Furthermore, we review the applications of complexity estimates for gene transcription regulatory regions analysis, the alignment-free sequences comparison methods, and the compression-based complexity approaches.

The rest of the review follow standard scheme—methods and algorithms, results, and discussion. The section "Methods and algorithms for DNA sequence complexity" reviews the algorithms for DNA sequence complexity estimates. The "[Results"](#page-5-0) section present comparison of the complexity methods on the diferent sequence sets, online tools for sequence complexity analysis (summarized in the table), discuss low complexity for protein sequences, and the genome database compression methods based on the complexity. The ["Discussion](#page-6-0)" section summarizes recent fndings and actual applications for coronavirus genome analysis.

# **Complexity for segmentation and delineation of genome sequences**

The measures of compositional complexity coming from the statistical physics methods help to fnd abnormalities in linear genome structure and make corresponding segmentation (Karakatsanis et al. [2021](#page-9-1); Bernaola-Galván et al. [2023](#page-8-2)). Shannon information (Shannon [1948](#page-10-3)) as the frst measure of nucleotide frequencies allows delineation of complexity blocks, coding, and non-coding regions in a sequence (Deng et al. [2012\)](#page-8-3). Shannon information, as well as entropy, could be measured for nucleotides, dinucleotides, and oligonucleotides of any reasonable length (up to 10) in available genome sequences. Despite this measure is easy to count, it can separate real and artifcial sequences (Sadovsky et al. [2008](#page-10-1)). Chang and colleagues have shown that the Shannon information for sequences from complete genomes are much higher than for random sequences of the same size (Chang et al. [2005\)](#page-8-4). This observation raised the problem of artifcial sequence generation that resembles properties of real genome sequences (Wang et al. [2020\)](#page-11-3).

Fluctuations in nucleotide frequencies in genome regions allow find heterogeneous sequence regions at varying scale—from short gene regulatory regions (kilobases) to isochores and chromosome segments (megabases) (Bernaola-Galván et al. [2023](#page-8-2)). Thus, applications of complexity analysis could be listed by sequence size:

- 1) Short sequences (transcription factor binding sites, promoters, gene regulatory regions, small domains, and microsatellites (Orlov and Potapov [2004](#page-10-2); Safronova et al. [2016](#page-10-4)).
- 2) Medium size genome regions (genes, patching exon/ intron structures, distal gene enhancers) (Abnizova et al. [2007](#page-7-1); Deng et al. [2012](#page-8-3)).
- 3) Chromosome arms, and complete prokaryotic genomes (Agenis-Nevers et al. [2021](#page-7-0); Bonidia et al. [2022](#page-8-5); Bernaola-Galván et al. [2023\)](#page-8-2).

The concept of triplet periodicity class and a measure of similarity between such classes were introduced in (Frenkel and Korotkov [2008](#page-8-6)). Triplet periodicity in DNA is related to coding sequence properties. It could be used to fnd ORF (open reading frame) shifts (Frenkel and Korotkov [2009](#page-8-7)).

Suvorova et al. [\(2014](#page-11-4)) compared periodicity search methods in DNA sequences. It was shown that combination of spectral methods and information decomposition methos is necessary to defne hidden periodicities with high mutation rate. Suvorova and Korotkov [\(2015](#page-11-5)) studied triplet periodicity diferences inside and between genomes extending the approach discussed by Dios et al. ([2014\)](#page-8-8).

Visible elements of low complexity regions in a genome are tandem repeats (Benson [1999;](#page-8-9) Frenkel et al. [2017](#page-8-10)). Such tandem (tail-to-tail) repeats are considered as a kind low complexity region. Tandem consist of tens to hundreds of residues of a repeated pattern, such as *atcatcatcatcatc* ("*atc*" repeated). They are classifed as mini and microsatellites (Jurka et al. [2007\)](#page-9-2). Molecular mechanism of replication slippage lead reproducing of tandem repeats. Tandem duplications are common for cancers (Li et al. [2020](#page-9-3)) and may occur in somatic cells at larger scale. Enrichment of head-to-tail somatic segmental tandem duplications in genome defned as the tandem duplicator phenotype also defnes lower sequence complexity (Menghi et al. [2018](#page-10-5)). There are set of computational tools such TRF (Tandem Repeat Finder) (Benson [1999;](#page-8-9) Frenkel et al. [2017](#page-8-10)) and ULTRA (Olson and Wheeler [2018\)](#page-10-6) to effectively search for degenerated tandem repeats (Delucchi et al. [2021](#page-8-11)).

There are set of methods for tandem repeat search—mreps (Kolpakov et al. [2003](#page-9-4)), TRStalker (Pellegrini et al. [2010](#page-10-7)), T-REKS (Jorda and Kajava [2009\)](#page-9-5), G-IMEx (Mudunuri et al. [2010\)](#page-10-8). The methods for tandem repeat search are limited due to sensitivity to nucleotide deletions and insertions.

Korotkov et al. [\(2022](#page-9-6)) studied triplet and *k*-mer periodicities in relation to genome adaptation. The grouping of bacterial genomes by periodicity in repeat composition was shown. Plant genomes present special case for genome complexity studies. There are abundant repeat elements, transposons and satellites. Korotkov et al. ([2021](#page-9-7)) found highly divergent tandem repeats in the rice genome. Recently, Rudenko and Korotkov ([2023\)](#page-10-9) classifed tandem repeats (TRs) in the *Capsicum annuum* (pepper plant) genome.

#### **Repeat search in genomes**

The complexity measures were used for genome assembly, genome segmentation, search for low complexity regions (Gusev et al. [1991](#page-8-0)) and repeat masking (Jurka et al. [2007\)](#page-9-2) from the time of frst available genome data. RepeatMasker software tool is widely used to identify and mask repetitive genome elements, including low-complexity sequences (Jurka et al. [2007;](#page-9-2) Tarailo-Graovac and Chen [2009](#page-11-6)). Interspersed sequence repeats could be treated as low complexity regions of genome. Such repeats play important roles in the evolution, genome variation, and instability, cause the disease. RepeatMasker algorithm searches and classify the repetitive sequences using library of known repeats. RepBase (Jurka et al. [2007](#page-9-2)) and Dfam (Hubley et al. [2016\)](#page-9-8) databases were most frequently used for masking genome repeats. Due to growth of new sequencing data, especially for non-model species, new msRepDB database became has become more popular for multi-species genome repeat analysis (Liao et al. [2022](#page-10-10)).

Searching for dispersed repeats in large eukaryotic genomes raises technical and methodical problems. Transposable elements are class of dispersed genome repeats widely represented in mammalian genomes. After insertion in a new position in the genome, Transposable elements accumulate mutations, which complicate their identifcation and annotation. New Highly Divergent Repeat Search Method suggested by Suvorova et al. [\(2021](#page-11-7)) make repeat search more efective than standard RepeatMasker. Recently, Korotkov et al. ([2023](#page-9-9)) presented method for dispersed repeats search in bacterial genomes using an iterative procedure.

Low complexity heterochromatic regions of human genome centromeric such satellite arrays remained not completely sequenced till last year (Nurk et al. [2022\)](#page-10-11). The T2T (Telomere-to-Telomere) Consortium fnished complete sequencing of reference human genome (Nurk et al. [2022](#page-10-11)). New repeat elements in the genome were found previously unknown satellite arrays and mobile elements (Hoyt et al. [2022](#page-9-10)). Thus, interspersed repeats yet to be found despite detailed previous sequencing and genome assembly. The example of new repeat structure is Short Interrupted Repeat Cassette (SIRC) found in the *A. thaliana* genome (Gorbenko et al. [2023\)](#page-8-12).

#### **Complexity for next‑generation sequencing reads**

The complexity estimates are important for NGS reads mapping (te Boekhorst et al. [2016;](#page-11-8) Abnizova et al. [2017\)](#page-7-2) and sequencing error correction. It was shown that the entropy in the sequencing reads not allow accurate mapping onto a reference genome. Moreover, low complexity of the reads relates to technological problem of sequence detection in Illumina sequencing platform (te Boekhorst et al. [2016](#page-11-8)). Some programs for sequencing error correction may introduce new errors in reads that overlapping low complexity regions. New error correction tool for Illumina sequencing data, BrownieCorrector, specially checks only the reads that overlap with highly repetitive (low complexity) regions in the genome (Heydari et al. [2019\)](#page-9-11). The complexity estimates were used for large plant genome analysis—to analyze the repetitive sequence fraction in wheat (Sergeeva et al. [2014](#page-10-12)).

#### **Complexity methods for proteins**

Low complexity, repetitive protein sequences with a limited amino acid composition are common and important for the protein structure and function (Alba et al. [2002](#page-7-3); Ntountoumi et al. [2019](#page-10-13); Jarnot et al. [2020](#page-9-12); Lee et al. [2022](#page-9-13)). Intrinsically disordered proteins have lower sequence complexity than ordered proteins, but have unique functions (Uversky [2016](#page-11-9)). There are set of tools for search of low complexity regions in proteins: SubSeqer (He and Parkinson [2008\)](#page-9-14), 0j.py (Wise [2001](#page-11-10)), ProBias (Kuznetsov [2008](#page-9-15)). The Complexity tool has also universal option for amino acid sequences estimates as well as for other alphabets (RNA, grouped amino acids, binary DNA alphabet) (Orlov and Potapov [2004](#page-10-2)).

# **Complexity methods for gene regulatory regions analysis**

Regulatory regions of gene transcription promoters, transcription factor binding sites, and its cluster also present hierarchical structure to be studied by the complexity methods (Abnizova et al. [2005](#page-7-4)). The problem is to fnd signal in gene promoter region and analyze their possible combinations (Vityaev et al. [2001,](#page-11-11) [2002;](#page-11-12) Voropaeva et al. [2019](#page-11-13)). Clusters of diferent transcription factor binding sites revealed by ChIP-seq technology (Chen et al. [2008](#page-8-13)) provide data for combinatorial analysis of such regions (Dergilev et al. [2022](#page-8-14)). It was shown that promoter sequences have varying text complexity, and this feature is statistically signifcant (Simões et al. [2021](#page-11-14)). But it is not enough for fnding of transcription factor binding sites or weak signal for nucleosome positioning (Orlov et al. [2006a,](#page-10-14) [b](#page-10-15); Goh et al. [2010](#page-8-15)). However, the problem is to reveal the signals in DNA sequence itself, and deal with overrepresentation of the motifs (Abnizova et al. [2005\)](#page-7-4). Note MEME software for analysis of repeated signals, such as transcription factor binding sites, in a sequence set (Tognon et al. [2023\)](#page-11-15). So, the entropy estimates and text linguistic methods could not be used directly for combination of transcription factor elements. Recently, an extension of complexity measure called Abelian complexity was suggested for prediction of gene regulatory regions (Wu et al. [2019\)](#page-11-16).

Analysis of genes and gene regulatory regions raised the challenge of searching for regions with low complexity (Hancock [2002;](#page-9-16) Wan et al. [2003\)](#page-11-17). It could be used to fnd borders between coding and non-coding gene regions. Intuitively, the complexity of a symbolic sequence refects an ability to represent a sequence based on some structural features of this sequence that need a repeated pattern—simple sequence repeats (Hancock [2002\)](#page-9-16), recognizable direct and inverted repeats (Cox and Mirkin [1997\)](#page-8-16). Following (Orlov and Potapov [2004](#page-10-2)) we note the methods of clusterization of cryptically simple sequences (Alba et al. [2002\)](#page-7-3); evaluation of the alphabet-capacity *l*-gram (combinatorial complexity and linguistic complexity) (Kisliuk et al. [1999](#page-9-17); Troyanskaya et al. [2002\)](#page-11-18); complexity measures by Lempel and Ziv (Gusev et al. [1991;](#page-8-0)1999; Chen et al. [1999;](#page-8-17) Dai et al. [2013](#page-8-18)); stochastic complexity (Orlov et al. [2002\)](#page-10-16), and grammatical complexity (Jimenez-Montano et al. [2002\)](#page-9-18).

# **Alignment‑free sequences comparison and visual methods**

Visual presentation of DNA sequence in 2D and 3D also gives background for repeat search and new mathematical methods development (Dai et al. [2006;](#page-8-19) Xie and Mo [2011;](#page-11-19) Mo et al. [2018](#page-10-17)). Note chaos game presentation, new approaches such as algebraic biology to find patterns in genome sequences (Petoukhov [2017\)](#page-10-18). We may also refer to these methods as to the methods of extended gene regions analysis.

Alignment-free approaches for sequence comparison assume compression-based sequence analysis. The alignment-free methods may be divided into two groups (Zielezinski et al. [2017\)](#page-11-20): methods based on comparison word frequencies (Provata et al. [2014](#page-10-19)) and methods that evaluate mutual informational between sequences. In general, alignment-free sequence comparisons used the concepts derived from IT, such as entropy and mutual information (Vinga [2014\)](#page-11-21).

There are also methods that cannot be classifed into these groups, including those based on the length of matching words, chaos game representation (Löchel and Heider [2021](#page-10-20)), iterated maps, as well as graphical representation of DNA sequences, which capture the essence of the base composition in a quantitative manner (de la Fuente et al. [2023](#page-8-20)).

### **Compression‑based complexity estimates**

Discussing the compression-based sequence analysis note the general concept to estimate the complexity of symbolic sequence (text) suggested by Kolmogorov ([1965\)](#page-9-19). He proved that there exists an optimal algorithm or binary program *p* for a binary string *s* generation. The Kolmogorov complexity, *K* is the length |*p*| of a shortest binary program *p* that computes *s* in a universal Turing machine and halts (Turing [1936](#page-11-22)). Complexity  $K(s) = |p|$  is the size of compressed storage *p*—the minimum number of bits required to computationally reproduce the string *s*. In general, the Kolmogorov complexity is not computable in reasonable time for arbitrary sequence. Various constructive realizations of nonoptimal coding have been developed (Lempel and Ziv [1976](#page-9-20)), including applications for DNA analysis (Gusev et al. [1999](#page-9-21); Antão et al. [2018](#page-8-21); Li and Vitányi [2019\)](#page-10-21).

The concept of the complexity of a finite symbolic sequence as the compression size was introduced by Lempel and Ziv (Lempel, and Ziv [1976](#page-9-20)). Initially, this approach was implemented for analyzing DNA by Gusev and coauthors (Gusev et al. [1991;](#page-8-0) [1999\)](#page-9-21). Based on this approach, we presented the Internet-available tools LZcomposer ([http://](http://wwwmgs.bionet.nsc.ru/mgs/programs/lzcomposer/) [wwwmgs.bionet.nsc.ru/mgs/programs/lzcomposer/](http://wwwmgs.bionet.nsc.ru/mgs/programs/lzcomposer/)) (Orlov et al [2003\)](#page-10-22) and complexity (Orlov and Potapov [2004\)](#page-10-2). Dai et al. ([2013](#page-8-18)) used Lempel–Ziv decomposition (LZ-words) for sequence comparison without alignment. Note that Lempel–Ziv complexity algorithm could be applied to any sequence of signals (physiological time series) to study repeats and irregularities (Zhang et al. [2016](#page-11-23)). Thus, the same algorithm and software could be applied for non-DNA arbitrary alphabet. A relative Lempel–Ziv complexity measure was used for alignment-free sequence comparison (Liu et al. [2012](#page-10-23)). Pirogov et al. [\(2019](#page-10-24)) used Lempel–Ziv complexity, and the match complexity measure to analyze the relationship between the complexity and gene function. Enrichment of gene content and development genes in high-complexity genome regions was shown. Hosseini et al. ([2020\)](#page-9-22) developed Smash++, an alignment-free tool to fnd and visualize small- and large-scale genomic rearrangements between two DNA sequences. This tool also exploiting a data compression technique to fnd the rearrangements.

# **Methods and algorithms for DNA sequence complexity**

## **General classifcation of complexity approaches**

We overview approaches for sequence complexity measurement in the general scheme (Fig. [1\)](#page-4-0). DNA sequence complexity as well as protein sequence complexity methods could be broadly classifed into large groups—entropy-based and compression-based methods.

Entropy based methods of complexity estimates include word frequency (linguistic) approaches, Shannon entropy and its variants. Compression based methods include modifcations of Lempel–Ziv compression scheme, could be applied for repeat search in genomes (direct, inverted, generated) and alignment-free genome comparisons. Spatial (3D) visualization of linear sequence, fractal presentation,

<span id="page-4-0"></span>

sequence polarization, and other techniques could be used for genome analysis. Basically, protein sequence complexity estimates use entropy approaches, but may refer to all the methods for DNA complexity.

#### **Algorithms for DNA sequence complexity estimates**

Several estimates of complexity were incorporated to the complexity tool to compare diferent approaches (Orlov and Potapov [2004\)](#page-10-2). It includes frequency of nucleotide content (Wootton and Federhen [1996\)](#page-11-24), entropy estimates, and linguistic complexity (Gabrielian and Bolshoy [1999](#page-8-22); Troyanskaya et al. [2002\)](#page-11-18). By applying *l*-gram trees for the sequence representation in the complexity software the operation time for computation was optimized. We further refer to (Orlov and Potapov [2004\)](#page-10-2) for the examples and details of sequence complexity algorithms.

Since main complexity algorithms were frst published in 2000s, the software implementations difer in sequence size to be processed, optimization, and the applications areas. Though novel additions such as long-range correlations (Abnizova et al. [2007](#page-7-1)) and polarization coding (Zimnyakov et al. [2023](#page-11-2)) difer from information-based and compressionbased techniques.

The Hurst exponent estimate for long-range correlation was added to the software to measure dependencies in DNA sequences (Orlov et al. [2006a](#page-10-14), [b](#page-10-15)). It was shown that the complexity of introns and regulatory regions is lower than that of coding regions, while Hurst exponent is larger due to long-range correlation between transcription factor binding sites (Abnizova et al. [2007\)](#page-7-1). Promoter sequences have lower complexity than protein coding regions. Long-range correlation analysis tool was implemented in CorGen software (as [http://corgen.molgen.mpg.](http://corgen.molgen.mpg.de) [de\)](http://corgen.molgen.mpg.de) (Messer and Arndt [2006\)](#page-10-25). The examples of sequence complexity for transcription factor binding sites were considered (Orlov et al. [2006a,](#page-10-14) [b](#page-10-15)). It was noted that the DNA sequence of transcript factor binding sites have in average lower complexity than protein coding regions.

Naumenko et al. ([2018\)](#page-10-26) used complexity estimates to reveal artefacts in short sequencing read mapping on a chromosome (aligner artefacts) (te Boekhorst et al. [2016](#page-11-8); Naumenko et al. [2018;](#page-10-26) Subkhankulova et al. [2021](#page-11-25)).

Nucleotide sequences containing human mutation sites are associated with varying sequence complexity related to mutagenesis mechanism (Chuzhanova et al. [2003\)](#page-8-23). Complexity estimates for the analysis of mutation sites (SNP containing regions) confrmed presence of low complexity regions at the fanking sites of mutation/polymorphism position (Safronova et al. [2015](#page-10-27); [2016\)](#page-10-4).

Nucleotide sequences forming non-B DNA structures (not double DNA helix) have repeated patterns as palindromes that can form hairpins, cruciform or triplexes. To analyze the sequences potentially forming non-B DNA structures the NeSSie tool was presented (Berselli et al. [2018](#page-8-24)).

Gene expression regulation studies (Orlov and Baranova [2020;](#page-10-28) Voropaeva et al. [2019\)](#page-11-13) give broad feld for application of application of information and entropy measures. Nucleotide sequences containing binding sites of many protein transcription factors have symmetrical structure due to contacts with protein dimers. Thus, due to presence of the repeated elements the transcription factor bindings sites have lower sequence complexity. Transcription factor binding sites have been catalogued in the databases such as TRRD, TRANSFAC, and JASPAR (Heinemeyer et al. [1998](#page-9-23); Sandelin et al. [2004](#page-10-29)) flled by data high-throughput sequencing technologies (ChIP-seq, ATAC-seq and related approaches) (Chen et al. [2008](#page-8-13)). The clusters of transcription factor (TF) binding sites in genomes were constructed based on ChIP-seq data (Dergilev et al. [2016,](#page-8-25) [2022\)](#page-8-14). The effect of lower complexity estimates was shown for longer gene regulatory regions (with multiple TF binding) in plants (Dergilev et al. [2022\)](#page-8-14). Recently, cooperative efect of transcription factor binding in sequential and spatial proximity was shown using chromatin conformation capture data (Vadnala et al. [2023](#page-11-26)), thus extending the theory of chromosome and high order regulatory codes.

Note recent work original by Zimnyakov et al. [\(2023\)](#page-11-2) on revealing and visualization of sequence dependencies using so called polarization coding. It refers to 2D sequence visualization for pattern search (Dai et al. [2006\)](#page-8-19). The polarization coding presents nucleotide sequence in a two-dimensional phase screen, where each element corresponds to a specifc nucleotide. The polarization-based technique was shown on the model data from a comparative analysis of the spike protein gene sequences of the SARS-CoV-2 virus complementing other complexity-based works on this topic (Akbari Rokn Abadi et al. [2023](#page-7-5)).

# <span id="page-5-0"></span>**Results**

# **Comparison of the methods and analysis of sequence sets**

The complexity estimates for diferent classes of genome sequences—exons, introns, regulatory nucleotide sequences—confrmed general theory about overlapping genetic codes suggested by E.N.Trifonov (Trifonov [1989,](#page-11-1) [1990](#page-11-0)). The more genetics messages have the sequence, the higher its complexity is. It was demonstrated that the complexity of exons is, on average, higher, whereas that of introns is lower (Orlov and Potapov [2004\)](#page-10-2). The alteration in the local complexity for splicing sites was shown using sequences the SpliceDB database (Burset et al. [2001\)](#page-8-26). The splicing sites in eukaryotic genes have intermediate place between protein coding regions (exons) and non-coding regions (introns). The average complexity of protein coding genes is higher than for non-coding, as it might be expected (short sequence repeats, simple repeats and polytracks (like AAAA…, TTTTT…) are common for introns making lower complexity). So, the average complexity of splicing sites sequence has corresponding intermediate place between complexity exons and introns (Orlov and Potapov [2004](#page-10-2)).

1372 Biophysical Reviews (2023) 15:1367–1378

The complexity estimates were used for large eukaryotic genome analysis—in plants. To analyze the repetitive sequence fraction in plant genomes such as wheat Sergeeva et al. ([2014](#page-10-12)) used RepeatMasker program ([http://www.](http://www.repeatmasker.org/) [repeatmasker.org/](http://www.repeatmasker.org/)) and calculated GC content and total content of satellites, simple repeats, and low complexity regions (Orlov et al. [2006a,](#page-10-14) [b](#page-10-15)).

To search for satellite repeat structures such as simple sequence repeats (GAA)n(GGA)m and telomeric (TTTAGG G)n satellites and inverted repeats in chromosome 5B 454 sequences, the authors used a custom script based on the Lempel–Ziv approach, which identifed the perfect satellite repeat tracts and inverted, as well as direct, repeat structures in DNA sequences (Sergeeva et al. [2014\)](#page-10-12). This program works with diferent types of repeats and does not require sequence alignment. The algorithm implements structural and comparative analysis of the signifcant amount of collections of DNA fragments of moderate length, developed at the Sobolev Institute of Mathematics (Gusev et al. [1999](#page-9-21); Orlov et al. [2003\)](#page-10-22). Analysis of genome inversions in plant as mutual genome comparison method was presented for rice genome (Suvorova et al. [2021;](#page-11-7) Zhou et al. [2023\)](#page-11-27). The lack of consensus concerning the biological meaning of entropy and complexity of genomes and the diferent ways to assess these data hamper conclusions concerning what are the causes of genomic entropy variation among species (Simões et al. [2021\)](#page-11-14).

## **Online tools for sequence complexity analysis**

There are novel online tools for the sequence complexity analysis and information processing that were not widely published, being presented at the conferences, such as ICGenomics (Orlov et al. [2020\)](#page-10-30). Table [1](#page-5-1) shows online tools for text complexity estimates for DNA and proteins.

<span id="page-5-1"></span>**Table 1** Existing tools for complexity estimates

Sequence type	Tool name	URL	Reference
Protein	RES repeatability scanner	http://cbdm-01.zdv.uni-mainz.de/~munoz/res/	(Kamel et al. $2019$ )
Protein	0j.py	https://doi.org/10.1093/bioinformatics/17.suppl_1.S288	(Wise $2001$ )
Proteins and DNA	$fLPS$ 2.0 (find low prob- ability subsequences)	https://biology.mcgill.ca/faculty/harrison/flps.html	(Harrison 2017)

<b>DNA</b>	CorGen	http://corgen.molgen.mpg.de/	(Messer and Arndt 2006)

Some online tools developed early are no longer accessible or have no web-version to be included to Table [1](#page-5-1). In CLC Genomics Workbench it is possible to calculate local complexity for both DNA and protein sequences (CLC bio was a bioinformatics software company that developed the software suite. It was subsequently purchased by QIAGEN [\(https://digitalinsights.qiagen.com/products-overview/disco](https://digitalinsights.qiagen.com/products-overview/discovery-insights-portfolio/analysis-and-visualization/qiagen-clc-genomics-workbench/) [very-insights-portfolio/analysis-and-visualization/qiagen](https://digitalinsights.qiagen.com/products-overview/discovery-insights-portfolio/analysis-and-visualization/qiagen-clc-genomics-workbench/)[clc-genomics-workbench/\)](https://digitalinsights.qiagen.com/products-overview/discovery-insights-portfolio/analysis-and-visualization/qiagen-clc-genomics-workbench/). The local complexity realizes measure of the diversity in the amino acid composition (Wootton and Federhen [1993\)](#page-11-28).

The AC tool was created for compression of amino acid sequences (Hosseini et al. [2019\)](#page-9-26). New version of his protein sequence compression tool, AC2, was proved to be more efective for specialized compression purposes (Silva et al. [2021\)](#page-10-31). The methods to detect such regions in protein include classical entropy, SEG (Wootton and Federhen [1993\)](#page-11-28) measure, and other tools such as LCR-eXXXplorer (Kirmitzoglou and Promponas [2015](#page-9-27)), see also Table [1.](#page-5-1)

#### **Low complexity analysis tools for protein sequences**

Low complexity regions of proteins are abundant in proteomes (Lee et al. [2022\)](#page-9-13). Low complexity regions in the proteins have important functional roles (Alba et al. [2002](#page-7-3)). They are highly conserved (Ntountoumi et al. [2019](#page-10-13)). Contrary to a widespread belief based on older and not complete data, low complexity regions have a signifcant, persistent, and highly conserved presence in many prokaryotes. Their specific amino acid content is linked to proteins with certain molecular functions, such as the binding of RNA, ions and polysaccharides (Jarnot et al. [2020\)](#page-9-12). Jarnot et al. ([2022\)](#page-9-28) show that existing methods for protein similarity search need improvements to count low complexity regions. Li and Kahveci ([2006\)](#page-9-29) defned new complexity measures to compute the complexity of a sequence based on a given scoring matrix, such as BLOSUM 62.

### **Database compression and large scale analysis**

Compression of genomes data for all the studied species is important by technical reasons. Growth of NGS (Next Generation Sequencing) data challenge analysis of multiple sequences and effective database storage (Agenis-Nevers et al. [2021\)](#page-7-0). Due to multiple sequence repeats this task could be solved using operational compression algorithms (variants of Lempel–Ziv compression). Mapping, quality control, and redundancy removal are related to sequence complexity. Comparison of existing tools Mardre (Expósito et al. [2017\)](#page-8-27), Bioseqzip (Urgese et al. [2020](#page-11-29)), and others to process such sequencing database by algorithmic complexity was presented by (de Oliveira Veras [2021](#page-8-28)). Overall, the operational complexity could be

used for duplicate removal and efective NGS sequencing database processing. Future application here are for cloud computing. Although the complexity of algorithms is not a new subject, there is a lack of materials within the area. Note frst works by Gusev et al. ([1999](#page-9-21)) for optimization of Lempel-Zive algorithm for DNA compression in terms of operation time. Performance of order *O(n log n)* and even *O(log log n)* was shown (de Oliveira Veras [2021\)](#page-8-28).

Mutual information measures (relative information could be used for complete genomes comparison, alignment free method (Veluchamyet al. [2021](#page-11-30)). At the same time, it could be used for compression of genome databases. The iDoComp tool may compress an individual genome using a reference data (Ochoa et al. [2015\)](#page-10-32).

## <span id="page-6-0"></span>**Discussion**

Previously, the complexity estimates were applied for analysis of decompositions of several complete bacterial genomes and fragments of eukaryotic chromosomes (Orlov et al. [2003](#page-10-22)). The complexity of sequences containing introns and regulatory regions is less than that of coding regions (Orlov and Potapov [2004](#page-10-2)). This observation is also valid in eukaryotes by estimating complexity of gene regions using several other complexity measures (Orlov et al. [2006a,](#page-10-14) [b\)](#page-10-15). Modern works on complexity use large scale calculations, present online tools for convenient and reproducible complexity analysis ((Jarnot et al. [2020](#page-9-12); Pirogov et al. [2019\)](#page-10-24). Recent studies described low complexity regions and compressed hundreds of complete genome sequences (Agenis-Nevers et al. [2021](#page-7-0); Munagala et al. [2022](#page-10-33)).

The problem of long-range correlations in genome could be also studied by sequence complexity methods. Experimental data on 3D genomics show presence of topologically associated domains (TAD) in eukaryotes (Li et al. [2012](#page-9-30); Kulakova et al. [2017](#page-9-31)). The DNA sequences from such chromosome regions are close in 3D cell space giving new point of view for long range genome correlations and topological code (Vadnala et al. [2023\)](#page-11-26). Such topologically proximal sequences should be analyzed by complexity methods (Kulakova et al. [2015\)](#page-9-32). Such TAD in chromosomes present higher level of sequence constraints (chromosome come) after triple coding, gene regulation signals, and nucleosome positioning. Thus, the theory of multiple genetic codes (Trifonov [1990](#page-11-0)) could be extended to new signals and repetitive sequence elements.

Repetitive sequences in annotated non-coding RNAs (ncRNAs) are found to constitute functional components that perform specifc biological functions (Zeng et al. [2022](#page-11-31)). Complexity measures are applied to novel data such as ncR-NAs (miRNA, siRNA, tsRNA, circRNA, lncRNA) in plants (Chao et al. [2022](#page-8-29)).

Alignment-free technique for sequence analysis is wide area for complexity algorithms. Information theory and data compression algorithms provide mathematical and computational tools to capture essential patterns in biological sequences (Bonidia et al. [2022](#page-8-5)). Recently, Munagala et al. ([2022\)](#page-10-33) investigated the use of compression-complexity based distance measures for analyzing genomic sequences. The proposed distance measure is used to successfully reproduce the phylogenetic trees for a mammalian dataset consisting of eight species clusters, a set of coronaviruses. *k*-mer and physic-chemical properties of nucleotides were recently used for SARS-CoV-2 genomes classifcation (Akbari Rokn Abadi et al. [2023](#page-7-5)).

Inversion index (number of genome inversion) was used for rice genome structure analysis (*Oryza sativa*) (Zhou et al. [2023](#page-11-27)). The authors used 73 genomes of rice (*O. sativa*) and the genomes of wild relative species to build a pan-genome inversion index for the reference genome sequence. Detailed analyses of these inversions show evidence of their efects on gene expression, recombination rate, and linkage disequilibrium. Complex plant genomes became object of the hidden periodicity search (Suvorova et al. [2021](#page-11-7)). Recombinations and inversions in plant genomes could be revealed by sequence compression technique (Chao et al. [2023\)](#page-8-30).

Scaling of computations in comparative genomics demand new algorithm development. Bello et al. ([2023\)](#page-8-1) used text compression to accelerate algorithms for Hidden Markov Models. Their work provides an efficient approach to big data computations with HMM using compression measures.

Overall, information theory is widely used for model development and data analysis for a variety of biologically derived data types ranging from molecular, sequence and phenotypic data in genomics and genetics to gene expression, protein and spectral data in transcriptomics, proteomics and metabolomics, respectively (Chanda et al. [2020](#page-8-31); Bartal and Jagodnik [2022](#page-8-32)). Sequence compression of whole genomes became routine procedure to be standardized in benchmark test—Sequence Compression Benchmark database (Kryukov et al. [2020\)](#page-9-0). Novel machine learning applications for classifcation of complete genome sequences also include sequence compression and complexity algorithms (Silva et al. [2021;](#page-10-31) Akbari Rokn Abadi et al. [2023\)](#page-7-5). We have reviewed here text complexity applications starting from basic defnitions and algorithms to the online applications and approaches for large-scale NGS analysis and machine learning techniques. The complexity analysis, sequence compression, and information-based methods gave raise to new fndings and challenges in molecular biophysics such as coronavirus genome studies (Munagala et al. [2022](#page-10-33)).

We conclude by mentioning new application areas of sequence complexity estimates in Big Data and Machine Learning methods. Statistical estimates of sequence complexity and periodicities patterns could be using in

Machine Leaning application as input parameters that might be even not interpretable (Silva et al. [2021](#page-10-31); Munagala et al. [2022;](#page-10-33) Balcı et al. [2023\)](#page-8-33). There are new AI solutions in bioinformatics that use additional sequence features and statistics as input parameters (Expósito et al. [2017;](#page-8-27) Penzar et al. [2023](#page-10-34)).
