11

# 12 Summary

13

Respiratory viruses including the human parainfluenza viruses (hPIVs) are a constant 14 burden to human health, with morbidity and mortality frequently increased after the acute 15 phase of the infection. Although is proven that respiratory viruses can persist *in vitro*, the 16 17 mechanisms of virus or viral products persistence, their sources, and their impact on chronic respiratory diseases in vivo are unknown. Here, we used Sendai virus (SeV) to 18 model hPIV infection in mice and test whether virus persistence associates with the 19 20 development of chronic lung disease. Following SeV infection, virus products were detected in lung macrophages, type 2 innate lymphoid cells (ILC2s) and dendritic cells 21 for several weeks after the infectious virus was cleared. Cells containing viral protein 22 23 showed strong upregulation of antiviral and type 2 inflammation-related genes that associate with the development of chronic post-viral lung diseases, including asthma. Lineage tracing of infected cells or cells derived from infected cells suggests that distinct functional groups of cells contribute to the chronic pathology. Importantly, targeted ablation of infected cells or those derived from infected cells significantly ameliorated chronic lung disease. Overall, we identified persistent infection of innate immune cells as a critical factor in the progression from acute to chronic post viral respiratory disease.

30

# 31 Introduction

32

Infections with respiratory RNA viruses pose a constant threat to human health. It 33 is estimated that Respiratory Syncytial Virus (RSV) alone is associated with more than 34 149.000 fatal cases of lower respiratory tract infection worldwide every year<sup>1</sup>. Among 35 paramyxoviruses, human metapneumovirus (hMPV) is responsible for approximately 36 643,000 hospitalizations and >16,000 deaths globally<sup>2</sup> every year, while hPIV accounts 37 for 725,000 hospitalizations and >34,000 deaths<sup>2,3</sup>. Within the pediatric population, acute 38 lower respiratory infections of viral etiology remain the leading cause of mortality in the 39 absence of a pandemic $^{4,5}$ . 40

In addition to the public health burden, acute respiratory viral infections at an early age are associated with the development of chronic lung diseases including asthma and chronic obstructive pulmonary disease (COPD), while infections later in life can lead to severe exacerbations of these conditions<sup>6,7</sup>. Influenza, RSV, hMPV, hPIV, and rhinovirus infections have been linked to development and progression of COPD and lung fibrosis

in humans, and more recently SARS-CoV-2 infection was implicated in chronic lung
diseases<sup>8-10</sup>.

It has been long established that RNA viruses can persist in humans. The best 48 studied example is measles virus that persists in the central nervous system of patients 49 with subacute sclerosing panencephalitis<sup>11,12</sup>. Other examples include Ebola virus 50 persistence in the testis<sup>13</sup> and chikungunya virus persistence in the joints<sup>14</sup>. In addition, 51 52 accumulating evidence suggests that respiratory viruses can establish persistent infections in the lung<sup>15-17</sup>. A comprehensive screening of post-mortem tissue from fatal 53 54 COVID-19 cases indicated presence of viral proteins, viral RNA, and infectious SARS-CoV-2 in the respiratory tract and other anatomical sites for longer than 30 days after 55 symptom onset<sup>15</sup>. Prolonged viral shedding has been reported in stem cell transplant 56 recipient patients<sup>18</sup> and immunocompromised patients infected with hPIV<sup>16,18</sup>. In addition. 57 high detection rates of hPIV3 in turbinate epithelial cells were reported in patients 58 suffering from post-viral olfactory dysfunction<sup>19</sup>. Prolonged exposure to viral RNA and 59 antigens, even in the absence of infectious viral particles, can work as immune stimulation 60 factors and contribute to chronic inflammation<sup>20,21</sup>. Therefore, it is critical to better 61 62 understand the mechanisms of virus or viral products persistence, the sources of the virus, and their impact on chronic respiratory diseases. 63

Here, we used respiratory infection with the murine paramyxovirus Sendai (SeV; recently renamed Murine respirovirus) to model hPIV infections in mice and study the persistence of virus and viral products and their impact on chronic lung disease. We show that viral antigens and RNA are present in specific innate immune cells populations in the lung long after the acute infection has been cleared. Importantly, we demonstrate that

infected cells, as well as cells derived from infected cells, play critical roles in maintaining
post-viral chronic lung pathology.

71

72 Results

73

Severe SeV lower respiratory tract infection leads to long term persistence of viral
 protein and RNA in the lung.

To evaluate whether mouse parainfluenza viruses persist in the respiratory tract. 76 77 we infected mice intranasally with a sublethal dose of SeV strain 52 that induced severe respiratory disease, as we and others have described previously<sup>22,23</sup>. We monitored 78 disease progression from 3 to 49 days post-infection (dpi), analyzing virus load and 79 presence of virus proteins in the lungs at these time points (Figure 1A). Day 49 post 80 infection has been established as a standard timepoint to study post-SeV chronic lung 81 disease as pathology has plateaued by then<sup>24</sup>. Acute weight loss following SeV infection 82 was maximal between days 7 and 8 post-infection, with animals losing about 25% of their 83 original weight (Figure 1B). All mice fully recovered their weights by day 35 post-infection. 84 85 As expected, virus RNA and infectious particles were detected in whole lung homogenates on day 3 post-infection, however, only viral RNA was detected on day 49 86 post-infection (Figure 1C). Immunofluorescence analysis for SeV nucleoprotein (NP) and 87 88 RNAscope analysis for NP RNA (mRNA and genomic RNA) revealed a different distribution of NP in the acute and chronic phases of the infection. While NP was mostly 89 90 detected in the airways lining epithelium on 3 dpi, SeV positive signal on day 49 post91 infection was mostly found in the alveolar compartment associated with infiltrating cells
92 (Figure 1D).

The chronic pulmonary disease caused by SeV was marked by intense tissue 93 remodeling, with expansion of basal epithelial cells (Krt5<sup>+</sup>) in well-delimited lesions. It was 94 noticeable that cells persistently expressing viral NP were adjacent to Krt5<sup>+</sup> lesions, 95 frequently organized in patches (Figure 1E, subpanels E1-3), while no NP<sup>+</sup> cells were 96 found in the unaffected areas of the lung (Figure 1E, subpanel E4). Overall, these 97 observations demonstrate that viral RNA and viral proteins are detectable in the chronic 98 phase of the infection, weeks after infectious virus has been cleared<sup>23</sup>, and indicate that 99 there is a differential distribution of virus-infected cells in the lung during the acute (day 100 3) and chronic (day 49) phases of the infection. 101

102

# Persistent SeV proteins are detected in type 2 innate lymphoid cells (ILC2s), macrophages and dendritic cells.

105 Given the diversity of cells that compose the lung inflammatory microenvironment during SeV-driven chronic disease and that most of the of persistent SeV NP<sup>+</sup> cells were 106 107 in the alveolar compartment (Figure 1D, E), we hypothesized that the persistent NP signal was mostly related to resident and infiltrating immune cells. We then used a panel 108 of markers representing cell types frequently found in SeV-driven infiltrates in mouse 109 110 lungs to characterize SeV NP<sup>+</sup> cells by immunofluorescence and flow cytometry. Initially, 111 after using antibodies against CD3 (T lymphocytes), CD11c and CD11b (dendritic cells -DCs), F4/80 (macrophages) and Thy1.2 (T cells and ILCs), we observed that CD11c<sup>+</sup>, 112 113 CD11c<sup>+</sup>CD11b<sup>+</sup>, F4/80<sup>+</sup> and CD3<sup>-</sup>Thy1.2<sup>+</sup> cells were found to be positive for SeV NP in

114 lung sections from 49 dpi (Figure 2A). Myeloid- cells, CD11c<sup>+</sup>, CD11b<sup>+</sup> and double-115 positive cells, likely DCs (Figure 2A-a1) and macrophages (Figure 2A-a2), were found 116 frequently co-expressing SeV NP, either diffusely dispersed through the lung section or 117 clustered surrounding blood and lymphatic vessels. Unexpectedly, SeV NP signal was 118 also detected in CD3<sup>-</sup>Thy1.2<sup>+</sup> cells in a considerably high frequency (Figure 2A-a3).

119 To quantify and better characterize the cell subtypes that are sources of persistent virus antigens, we employed multiplex spectrum flow cytometry to analyze SeV-infected 120 121 mouse lungs at the chronic stage of the infection (Figure S1). Single-cell suspensions 122 obtained from acute SeV infection yielded on average 13.8±2.9% live, NP<sup>+</sup> cells. On day 49 after infection, the percentage of live NP<sup>+</sup> cells was 2.12±0.7% (representative dot 123 plots in **Figure 2B** and quantitative analysis in **Figure 2C**). We then analyzed individual 124 125 cell subtypes to determine the percentage of SeV NP<sup>+</sup> cells withing each subset. Amongst lymphoid-origin cells, ILC2s displayed the highest percentages and MFI of NP expression 126 (15.7±3.5%) (Figure 2D and E, left panels). Meanwhile, tissue macrophages (TMs) 127 128 (12.01±1.3%) and DCs (8.65±3%) were the myeloid subsets with the highest percentages 129 of NP signal among the cell types analyzed (Figure 2D and E, right panels). Altogether, 130 our data strongly indicate that macrophages, ILC2s and dendritic cells are the main sources of persistent virus antigens during chronic SeV infection. 131

132

133 Innate immune cells sustain type 2-inflammation during SeV-driven chronic lung134 disease.

Macrophages, dendritic cells and ILC2s participate in the establishment of chronic
 lung disease upon SeV infection through the IL-33/IL-13 axis<sup>25</sup>. Finding these cells

137 harboring persistent viral products raised additional questions about their impact on the pathogenesis of chronic lung disease. We sorted ILC2s and macrophages from SeV-138 infected IL-13 reporter (sm13)<sup>26,27</sup> mouse lungs at 49 dpi and analyzed their 139 140 transcriptomic signatures against mock-infected animals to characterize their activation state. ILC2s displayed a total of 732 differentially expressed genes (DEGs) over mock, 141 142 with 276 being upregulated and 456 being downregulated (P<0.05 and LogFC>2) (Figure **3A**). We observed a significant increase of ILC2 hallmark genes<sup>28</sup>, including *Gata3*, *Rora*, 143 IL5, IL13, Areg, Klrg1, and II1rl1 (ST2) (Figure 3B), as well as genes known to be 144 145 increased in the context of RNA virus infection (Figure 3C). Gene set enrichment analysis 146 (GSEA) showed that lung ILC2s from SeV-infected were enriched in pathways previously linked to SeV infection<sup>29</sup>, including the TNFR2 non-canonical NF-kB pathway (Figure 147 148 **3G**). Moreover, DEGs from sorted ILC2s show signatures associated with type 2 immune 149 responses and inflammation, supporting the role of ILC2s in maintaining the chronic type 150 2 immunopathology observed in SeV-infected lungs at 49 dpi (Figure 3G). Lung 151 macrophages from SeV-infected mice displayed 478 upregulated DEGs compared to mock (Figure 3D), from which classical genes involved in Th2 inflammation<sup>30</sup>, including 152 153 Arg1, Chil3, Ccl11, Il1rl1 (ST2), and Il33 were significantly increased (Figure 3E). In addition, these macrophages had transcriptomic signatures associated to increased 154 phagocytic activity<sup>31</sup> such as Cd63, Cd68, and Fcgr2b (Figure 3F). Similar to what was 155 156 shown for ILC2s, upregulated genes in macrophages were enriched in GSEA signatures 157 directly involved in chronic lung disease (Figure 3G). These findings indicated that innate 158 immune cells display a strong gene expression polarization towards type 2 inflammatory 159 responses and show transcriptomic footprints that are indicative of virus infection and

160 chronic lung diseases, confirming their involvement in the pathogenesis of post-viral161 chronic lung disease.

162

# 163 Virus-infected cells and/or cells derived from them contribute to the chronic 164 inflammatory state following SeV infection.

165 Long-term exposure to viral antigens and RNA in the respiratory tract is likely to 166 have important implications on the tissue microenvironment. To directly evaluate the transcriptome of persistently infected cells, we generated a double-reporter virus by 167 168 inserting an eGFP and a Cre recombinase as independent genes between the N and the P genes of the SeV Cantell strain (rSeV-C<sup>eGFP-Cre</sup>) (Figure S2A). We then used rSeV-169 C<sup>eGFP-Cre</sup> to infect tdTomato reporter mice that contain a Cre reporter allele flanked by 170 171 loxP-STOP cassettes (Figure S2B). We harvested lungs on day 49 pi for flow cytometry and FACS analysis (Figure 4A). Infection with rSeV-C<sup>eGFP-Cre</sup> progressed in a similar way 172 as our previously described SeV-52 model. Weight loss of up to 20% of the original weight 173 174 was observed until day 9 post-infection, with steady recovery until no differences from uninfected animals by day 21 (Figure 4A). Upon transcription of the viral genome, Cre is 175 176 expressed and excises the loxed stop cassette that blocks the tdTomato gene construct leading to expression of the reporter. Virus-infected cells, cells that cleared the infection 177 178 in a non-cytolytic manner, and cells derived from these cells will have constitutive 179 expression of the tdTomato fluorescent protein (tdTom) (Figure S2B). At 3 dpi, the 180 frequency of tdTom<sup>+</sup> cells in infected lungs was 21.3%±0.6%, and this number decreased 181 to 10±2.6% at 49 dpi (Figure 4B-C, includes a representative sample). From these cells, 182 at 3 dpi 84.4%±3.8% were characterized as non-immune (CD45<sup>-</sup>) and 15.4%±3.8% were

183 characterized as immune cells (CD45<sup>+</sup>) (Figure 4D-E, includes a representative sample), similar to what we observe during SeV-52 acute infections. The proportion of non-immune 184 185 tdTom<sup>+</sup> cells at 49 dpi remained high (90.9%±0.3%) and immune cells accounted for 186 8.8%±0.2% of all tdTom<sup>+</sup> events (Figure 4D-E, includes a representative sample). As previously reported, the constitutive expression of tdTomato upon Cre exposure is 187 188 independent of further viral replication, and all tdTom<sup>+</sup> cells, even those that cleared the infection would express the reporter protein<sup>32</sup>. To differentiate cells persistently 189 190 expressing viral protein from all other tdTom<sup>+</sup> cells, we combined tdTom detection with 191 SeV NP staining. Using this strategy, we identified three distinct cell populations in tdTom reporter mice on day 49 after infection with rSeV-C<sup>eGFP-Cre</sup>: tdTom<sup>+</sup>NP<sup>-</sup>, tdTom<sup>+</sup>NP<sup>+</sup>, and 192 negative cells (Figure 4F). We then sorted these populations for transcriptome analysis. 193 194 To increase RNA yields, we used three pools of two individual infected animals for sorting. 195 In addition, we obtained negative cells from mock-infected tdTom reporter animals as controls. The samples were subjected to total RNA-seq. We found reads mapping to the 196 197 viral genome or the eGFP reporter gene in all three tdTom<sup>+</sup>NP<sup>-</sup> cell pools and in all three tdTom<sup>+</sup>NP<sup>+</sup> pools (Figure 4G). Alignment to the rSeV-C<sup>eGFP-Cre</sup> genome showed viral 198 199 reads mapping to multiple viral genes, including the polymerase L gene in some of the pools (Figure H), confirming that tdTom<sup>+</sup>NP<sup>-</sup> cells have been exposed to the virus either 200 201 by direct infection or through their progenitors.

After identifying two major cell subsets relevant to virus-host interactions in persistent SeV infection, we sought to understand their role in pathogenesis by comparing the host transcriptomic profiles of tdTom<sup>+</sup>NP<sup>-</sup> and tdTom<sup>+</sup>NP<sup>+</sup> cells. Transcriptomic analysis of the different pools showed differentially expressed genes (DEGs) in tdTom<sup>+</sup>NP<sup>-</sup> and tdTom<sup>+</sup>NP<sup>+</sup> cells over mock (Figure 5A) (p<0.05 and LogFC>2). Negative
cells showed no significant transcriptomic changes over mock (Figure 5A), suggesting
that only direct virus-host interactions lead to long-term host gene expression changes,
rather than a more widespread effect to non-infected cells in the lung.

210 From the identified DEGs, 2376 were exclusive of tdTom<sup>+</sup>NP<sup>-</sup> and 387 DEGs were exclusive of tdTom<sup>+</sup>NP<sup>+</sup> cells (Figure 5B). Gene Ontology (GO) analysis indicated that 211 tdTom<sup>+</sup>NP<sup>-</sup> cells have gene expression signatures associated to extracellular matrix 212 213 organization, epithelial cell migration, wound healing, lung epithelial cell differentiation, 214 tissue remodeling and keratinocyte proliferation (Figure 5C), of note, the extracellular 215 matrix organization factors Col1a1, Col3a1, Col5a1, and Fbln1, and the cell proliferation factors Cd34, Tgfb3, Cldn1, Egfr, and Fgf10, all included in the wound healing pathway 216 217 (Figure 5D).

Differently, tdTom<sup>+</sup>NP<sup>+</sup> DEGs included genes associated with mononuclear cell 218 proliferation and migration, response to virus, positive regulation of inflammatory 219 220 response, lymphocyte activation, and innate immune response (Figure 5C). Genes 221 involved in lymphocyte activation and proliferation included Cd44, Itab2, Cd274, Cd2, and 222 Card11. Among genes involved in positive regulation of innate immune responses, Cd68, 223 Chil3, Fcgr3, Fcer1g and Fcgr1 are examples of myeloid-related genes, Gata3, and Thy1 224 are examples of innate lymphoid-related genes (Figure 5D), and I/33 is a known gene involved in Type-2 immunopathology<sup>22</sup>. 225

Gene set enrichment analysis (GSEA) comparing tdTom<sup>+</sup>NP<sup>-</sup> and tdTom<sup>+</sup>NP<sup>+</sup> cell transcriptomes confirmed the distinct transcriptomes of these cell populations. Survivor tdTom<sup>+</sup>NP<sup>-</sup> cells had enriched signatures associated to tissue remodeling, keratinization, and tissue homeostasis-related pathways (**Figure 5E**). On the other hand, persistent tdTom<sup>+</sup>NP<sup>+</sup> cells had enriched signatures mapping almost exclusively to immune and inflammation-related pathways, such as myeloid cell development, innate immunity, lung cancer, and oxidative phosphorylation (**Figure 5E**). These observations indicate that while cells that cleared SeV infection initiate and maintain a transcriptomic program to control inflammation and to resolve lung injury, cells persistently exposed to viral products have a pro-inflammatory profile with potential implications on lung pathogenesis.

236

# Persistent infected cells and its progeny are directly involved in the progression of chronic lung disease.

We next set out to investigate the impact of persistent infected cells in the lung 239 240 chronic disease progression. To do this, we combined our rSeV-C<sup>eGFP-Cre</sup> with Creinducible Diphtheria toxin receptor (iDTR) mice<sup>33</sup>, where SeV-infected cells constitutively 241 express DTR. DTR-expressing cells would then be susceptible to specific ablation 242 243 following DT administration. We then intranasally injected the iDTR mice with either PBS (mock) or 2x10<sup>5</sup> TCID<sub>50</sub>/animal of rSeV-C<sup>eGFP-Cre</sup>, treated with two consecutive doses of 244 245 DT, and analyzed their lungs by flow cytometry at 5 dpi to check for depletion of infected cells (Figure S3A). The DT treatment did not impact disease progression, and both 246 247 infected groups lost up to 20% of their original weight and recovered thereafter (Figure 248 6B). Flow cytometry quantification of SeV NP<sup>+</sup> cells indicated that two consecutive DT 249 doses were sufficient to deplete more than 80% of infected cells (Figure S3B-C) as described previously<sup>33</sup>. To deplete persistent infected cells, we waited until 21 dpi to avoid 250 251 the acute and clearance phases of SeV infection and used the same 2-dose DT regime,

252 with the final time point for analysis at 49 dpi (Figure 6A). Infected groups showed the typical signs of disease progression following SeV infection, and the DT regime did not 253 254 cause weight loss in the 5 days following intraperitoneal administration (Figure 6B). As 255 expected, infected mice that were not treated with DT had the typical signs of chronic lung disease caused by SeV, including alveolitis, bronchiolization of the alveolar compartment, 256 and bronchoalveolar lymphoid tissue (BALT) formation<sup>22</sup> (Figure 6C). Noticeably, DT-257 mediated ablation of persistently infected and survivor cells decreased the intensity of the 258 259 lung disease (Figure 6C-D), and lung sections displayed minimal pathology compared with untreated controls. Targeted DT ablation of SeV NP<sup>+</sup> cells also significantly 260 261 decreased the area affected by chronic lesions, marked by intense agglomeration of basal stem cells (Krt5<sup>+</sup>) and transitory epithelial cells (Krt8<sup>+</sup>) (Figure 6E-F), hence 262 263 demonstrating that persistent infected cells and its progeny are directly involved in the progression of SeV-driven chronic lung disease. 264

265

# 266 Discussion

RNA virus-host interactions are proving more complex and intricated than they 267 268 were thought to be. Increasing evidence shows that a diversity of RNA viruses can remain in their host in different forms past acute illness recovery, clearance of infectious viral 269 particles and development of specific immunity, resulting in harmful long-term clinical 270 manifestations with epidemiological implications<sup>20,34,35</sup>. Frequently, persistent RNA 271 272 infections are found in very specific niches, for instance, the CNS, testis, ocular tissue, 273 and secondary lymphoid organs. Here, using a natural host-pathogen model, we describe 274 the implications of respiratory virus persistence in a non-canonical immune privileged site,

275 the lower respiratory tract. In accordance to previous reports for SARS-CoV2 and influenza virus<sup>17,36</sup>, we showed detection not only of SeV RNA from multiple viral genes 276 277 for up to 49 dpi, but also of viral antigens, indicating that some level of persistent viral 278 RNA translation is still in place during the persistent phase of the infection, even with undetectable infectious viral particles. Importantly, we identified ILC2, macrophages and 279 280 dendritic cells as the main cells harboring persistent viral products in the lung, and we demonstrate that depletion of cells that have been directly infected or those derived from 281 infected cells significantly reduce chronic post-viral lung disease. 282

283 Our data indicate that between the early stages of SeV infection and the later 284 chronic lung inflammation there is a major shift of viral antigen and RNA cell sources (Figures 1 and 2). As expected, based on previous reports<sup>37</sup> airway cells were the major 285 286 source of viral proteins and RNA on day 3 post-SeV infection. However, on day 49 postinfection cells in the alveolar compartment were the sources of viral products, with no 287 detectable virus RNA nor antigens in epithelial cells. Upon immunofluorescence and flow 288 289 cytometry, these viral product sources were characterized as dendritic cells, macrophages and ILC2s. One of the hallmarks of the chronic SeV-driven 290 291 immunopathology is the increased number of alternatively activated macrophages (AAMs) and monocyte-derived dendritic cells in infected mouse lungs<sup>38-40</sup>. These cells 292 were shown to partner with ILC2s, also found in increased numbers in this condition, 293 contributing to chronic type 2 inflammation in an IL-33/IL-13 axis-dependent manner<sup>25</sup>. In 294 295 light of our findings, we hypothesize that immune cells with phagocytic activity, such as 296 macrophages and dendritic cells, interact with SeV-infected epithelial cells and become 297 sources of viral RNA and protein, as previously shown that macrophages and dendritic cells remain positive for SeV RNA by qPCR for up to 21 dpi<sup>40</sup>. The transcriptomic signatures of sorted macrophages during SeV chronic lung disease support these observations, with strong Th2 polarization and increased expression of phagocytic activity-related genes (**Figure 3**), but no significant changes in markers suggestive of active viral infection (data not shown).

303 For the myeloid compartment, phagocytosis of viral-infected cells is a known 304 pathway whereby professional phagocytes could acquire viral antigens and even become infected. Unexpectedly, we found ILC2s as one of the most significant sources of 305 306 persistent viral subproducts following SeV infection. Since ILC2s lack phagocytic activity, 307 our results suggest that expression of SeV antigens is a consequence of viral infection. 308 ILC2s from SeV persistently infected lungs displayed upregulated ILC2 hallmark IL-2-309 STAT5 and Th2 inflammation genes, corroborating previous studies covering ILC2 roles in post-viral respiratory disease<sup>28,41</sup>. However, we also reported genes upregulated during 310 311 viral infection, such as *lfitm1* and *Traf1*, involved in viral infection response pathways. To 312 the best of our knowledge, this is the first report demonstrating the persistent expression 313 of viral antigens in innate lymphoid cells.

Typical infections caused by highly cytopathic viruses were thought to follow a canonical chain of events culminating with cell lysis, tissue damage, release of proinflammatory mediators, and viral clearance. Nonetheless, it was recently shown that cells can overcome viral infection in a non-lytic way and either the infected surviving cell or its daughter cells have diverse long-term implications<sup>42-46</sup>. For instance, influenza A virus (IAV)-directly infected or derived from infected club cells showed a pro-inflammatory profile that implicated in lung pathology in mice<sup>42</sup>, while also exerting a protective role 321 against secondary infections<sup>43</sup>. Survivor epithelial cells from another respiratory 322 orthomyxovirus infection, influenza B virus (IBV), were also shown to be critical to 323 maintain respiratory barrier function in a murine model of IBV infection<sup>45</sup>. The infection by 324 SeV, a murine respirovirus, also left a significant percentage of survivor cells in mouse 325 lungs, from which the majority were epithelial cells (Figure 4). Interestingly, even as early 326 as 3 dpi, CD45<sup>+</sup> immune cells were positive for the reporter tdTom, indicating active viral replication or phagocytosis of infected cells. After 49 days of the infection, CD45<sup>+</sup> immune 327 cells were still part of the tdTom<sup>+</sup> cell pool, suggesting that for paramyxoviruses the 328 329 diversity of survivor cells goes beyond the epithelial compartment.

330 As suggested previously, survivor cells could act as long-term sources of viral antigens<sup>47</sup> with potential role in chronic lung disease development and lung healing. We 331 332 successfully combined the cell-fate tracing system using Cre-dependent tdTom reporter mice/rSeV-C<sup>eGFP-Cre</sup> with virus antigen detection to better characterize survivor and virus 333 334 persistent cells. For both survivor cells with or without persistent expression of SeV NP 335 (tdTom<sup>+</sup>NP<sup>-</sup> and tdTom<sup>+</sup>NP<sup>+</sup>), SeV RNA was detected and coverage analysis after RNAseg indicated multiple viral genes represented, including the polymerase L gene, 336 337 suggestive of low replicative levels in SeV persistent cells. Based in our previous cell characterization of persistent SeV-antigen expressing cells, we hypothesized that the 338 survivor tdTom<sup>+</sup>NP<sup>+</sup> cells were exclusively immune cells. 339

Cells that manage to survive a non-cytolytic clearance of RNA viruses after the acute stages of the infection can maintain abnormal transcriptomic footprints for weeks<sup>46</sup>. After following SeV-infected mice for a long-term post-infection (49 dpi) but also keeping in mind that the chronic lung disease is present at this timepoint, we assessed the 344 transcriptomic signatures of tdTom<sup>+</sup> cells in comparison with negative and mock cells. Surprisingly, deep transcriptomic changes were observed only in survivor tdTom<sup>+</sup>NP<sup>-</sup> and 345 tdTom<sup>+</sup>NP<sup>+</sup> cells. Negative cell transcriptomes resembled mock cells, giving no significant 346 347 differentially expressed genes. A similar observation was made with uninfected cells from IBV infected mice at 14 days in comparison with their correspondent controls<sup>45</sup>. These 348 349 findings indicate that at later stages of paramyxovirus infection, the lung transcriptomic 350 changes are a result of direct virus-cell interaction events and not due to responses to 351 secondary secreted mediators. Given the diversity of survivor cells that we described from 352 a respiratory paramyxovirus infection, we expected correspondent diverse roles in 353 pathogenesis. We observed that tdTom<sup>+</sup>NP<sup>-</sup> cells presented gene expression signatures 354 matching to tissue remodeling, wound healing, and lung regeneration pathways, typically 355 seen in survival epithelial cells from respiratory orthomyxovirus infections<sup>42,45</sup>. However, infected cells expressing persistent SeV antigens (tdTom<sup>+</sup>NP<sup>+</sup> cells) displayed a different 356 357 gene signature enriched in proinflammatory genes, matching the gene expression profiles 358 we described from sorted innate immune cells from SeV-driven chronic lung disease.

359 To address the impact of SeV-survivor cells in the subsequent chronic lung 360 pathology, we employed Cre-inducible diphtheria toxin receptor (iDTR) mice in combination with our rSeV-C<sup>eGFP-Cre</sup> virus and performed DT-mediated ablation of viral 361 infected cells and its progeny way after the timepoints were SeV infection is considered 362 363 cleared. Unfortunately, we were not able to specifically deplete persistent SeV-survivor 364 NP<sup>-</sup> or NP<sup>+</sup> cell populations one at a time at this point due to lack of appropriate tools 365 available to us. Regardless of the fact that DT ablation affects all DTR-expressing 366 populations (persistent infected, virus-cleared, and its progeny), and not only the survivor NP<sup>+</sup> cells, there was a significant impact on pathogenesis, reinforcing that the chronic Th2-biased inflammation induced by survivor SeV NP<sup>+</sup> cells is a key factor to the maintenance of the "post-viral" chronic lung disease.

370 In summary, our study demonstrates that paramyxovirus RNA and antigens persist 371 in the lower respiratory tract associated with innate immune cells for months after the viral 372 infection is thought to be cleared. More importantly, clearance of SeV infection is not complete, leaving a complex collection of survivor cells including epithelial and immune 373 cells, each carrying distinct transcriptomic signatures. Long-term expression of virus 374 375 antigens by survivor cells was proven to be a key factor for the immunopathology of 376 paramyxovirus infection as a persistent source of activation for innate immune cells, which leads to maintenance of the robust type 2 environment in the SeV-driven chronic 377 378 lung disease. Our data not only shed light into the cellular fate following respiratory infections and its long-term implications on chronic disease, but also pave the road for 379 380 studies to further characterize the functions of persistent virus antigen-expressing cells 381 and designing antiviral strategies.

382

#### 383 Materials and Methods

384

# 385 Mice, Virus Infection and Virus Titration

Seven- to 9-weeks old female wt C57BL/6 mice were either bred in house or purchased
from Taconic Biosciences (Rensselaer, NY). B6.Cg-Gt(ROSA)26Sor<sup>tm14(CAG-tdTomato)Hze</sup>/J
(tdTomato) and C57BL/6-Gt(ROSA)26Sor<sup>tm1(HBEGF)Awai</sup>/J (iDTR) mice were either bred in
house or purchased from The Jackson Laboratory. B6.129S4(C)-II13<sup>tm2.1Lky</sup>/J (sm13)

mice were previously described<sup>26,27</sup> and bred at Washington University in St. Louis. 390 Sendai virus strain 52 (SeV-52) stocks were expanded in 10-days-old embryonated 391 392 chicken eggs (Charles River Laboratories, Wilmington, MA) and virus titers were 393 determined using end-point dilution tissue culture infectious dose (TCID<sub>50</sub>) infectivity assays<sup>48</sup> in LLC-MK2 cells. For mice infections, animals were anesthetized with standard 394 395 doses of Xylazine/Ketamine and injected intranasally with 40 µL of either PBS or diluted virus to a final dose of 5x10<sup>4</sup> TCID<sub>50</sub> for SeV-52 or 5x10<sup>5</sup> TCID<sub>50</sub> for rSeV-C<sup>eGFP-Cre</sup>, 396 corresponding to 10 times the virus ID50 ensuring that all mice were infected. Mouse 397 398 groups were then monitored for weight loss as an indicator of disease progression for up 399 to 49 dpi. To obtain lung viral titers, lung lobes were homogenized in 0.1% Gelatin, clarified by centrifugation, and analyzed by infectivity assays in LLC-MK2 cells. iDTR mice 400 401 were administered with 100 ng of Diphtheria toxin (DT) (Sigma) intraperitoneally at days 3 and 4 for depletion of rSeV-C<sup>eGFP-Cre</sup>-infected cells. To achieve depletion of persistently 402 infected and survivor cells, DT treatment was performed at days 21 and 22 post-infection. 403

404

#### 405 Generation of rSeV-C<sup>eGFP-Cre</sup>

The full-length SeV Cantell viral antigenome sequence (NCBI accession number OR764764) was inserted into the pSL1180 vector flanked at the 5' by the T7 polymerase promoter and a Hammer-head Ribozyme (Hh-Rbz) and at the 3' by a second Ribozyme, and the T7 terminator. The reporter eGFP and the recombinase Cre genes were inserted as independent reading frames between the virus genes N and P, flanked by the duplicated N/P intergenic region. A NotI restriction site was inserted after the eGFP gene, as well as 4 nucleotides after the Cre gene to ensure the whole genome would meet the paramyxovirus "rule of six". Three helper plasmids were made by cloning NP, P, and L
genes of SeV Cantell into the pTM1 vector. All these plasmids were confirmed by
nanopore sequencing.

416 To rescue the recombinant virus, BSR-T7 cells grown in DMEM containing 10% FBS, 50ng/mL Gentamicin, 1mM Sodium Pyruvate, and 2mM L-Glutamine were 417 transfected with a plasmid's mixture containing 4.0 µg pSL1180- rSeV-C<sup>eGFP-Cre</sup> 1.44 µg 418 pTM1-NP, 0.77 µg pTM1-P and 0.07 µg pTM1-L using Lipofectamine LTX according to 419 manufacturer's guidelines. After a 5 h incubation, the medium was changed to infection 420 421 medium (DMEM containing Pen/Strep, 35% Bovine Serum Albumin (BSA) (Sigma), 5% NaHCO<sub>3</sub>) with 1 µg/mL TPCK-treated trypsin (Worthington Biochem. Corporation), then 422 423 cells were incubated at 37°C. The monolayers were monitored daily for eGFP expression 424 and harvested on day 4 post-transfection. After 3 freeze-thaw cycles, the supernatants were clarified by centrifugation and used to infect 10-day-old embryonated chicken eggs 425 through the allantoic cavity. After incubation for 40 hours at 37°C, 40 – 70% humidity, the 426 427 allantoic fluids were harvested and the TCID<sub>50</sub> was measured using LLC-MK2 cells.

428

# 429 RNA extraction and RT-qPCR

Lung samples were homogenized in TRIzol (Ambion Inc.), and total RNA was extracted following manufacturer's guidelines. To remove any trace of DNA contaminants, 1 µg of total RNA was treated with DNAse I (Thermo scientific) following manufacturer's guidelines and cDNA synthesis was then carried out with the High-Capacity cDNA Reverse Transcription kit (Applied biosystems). For quantitative analysis by RT-PCR (qPCR), 10 ng/µL of cDNA was amplified using SYBR Green Mastermix (Thermofisher) 436 in a BioRad C1000 Touch thermal cycler (BioRad). SeV NP (forward 5-TGCCCTGGAAGATGAGTTAG-3', 5'-GCCTGTTGGTTTGTGGTAAG-3') 437 reverse 438 relative copy numbers were normalized to mouse GAPDH (forward 5-439 CTCCCACTCTTCCACCTTCG-3', reverse 5'-CCACCACCCTGTTGCTGTAG-3') and corrected for mouse alpha-Tubulin (forward 5'-TGCCTTTGTGCACTGGTATG-3', reverse 440 5'-CTGGAGCAGTTTGACGACAC-3') expression as described previously<sup>22</sup>. 441

442

# 443 Generation of recombinant huFc-SeV NP antibody

444 Sequence of the mouse variable heavy and kappa chains were obtained by using SMARTer 5' RACE technology (Takara Bio, USA) adapted for antibodies to amplify the 445 variable genes from heavy and kappa chains for each hybridoma based on isotype. 446 447 Briefly, RNA was extracted from each hybridoma using Qiagen RNeasy Mini Kit (Qiagen, Valencia, CA), followed by first stand cDNA synthesis using constant gene specific 3' 448 primers (GSP) based on the specific isotype of the hybridoma and incubation with the 449 450 SMARTer II A Oligonucleotide and SMARTscribe reverse transcriptrase. Amplifying PCR 451 of the first stand cDNA product was then performed using SegAmp DNA 452 Polymerase (Takara) with a nested 3' primer to the constant genes and a 5' universal primer based on universal primer sites added to the 5' end during cDNA generation. 453 Purified PCR product was then submitted for Sanger sequencing using 3' constant gene 454 455 primers (GeneWiz, South Plainfield, NJ). Sequence results were blasted against the IMGT human databank of germline genes using V-Quest (http://imgt.org) and analyzed 456 for CDR3/junction identity and V(D)J usage. Clones were chosen from each clonal family, 457 458 and DNA was synthesized and cloned in-framed into pcDNA3.4 vector containing a

459 human IgG1 constant region and a human kappa light chain constant region, making a chimeric mouse variable/human constant antibody. (GenScript USA Inc., Piscataway, 460 NJ). Heavy and light cloned plasmids were mixed 1:1 and transfected into Expi293 cells 461 according to manufacture protocol (ThermoFisher). Supernatants were harvested five 462 days later and purified on protein A/G Hi-Trap columns on an AKTA FPLC (Cytiva). 463 464 Antibody was eluted off the columns at low pH and dialyzed against 1xPBS. Antibody quantitation was performed by 280/260 absorbance on a Nanodrop spectrophotometer 465 466 (DeNovix).

467

# 468 Histopathology and tissue immunofluorescence

Mice lungs were perfused with 8 mL PBS and inflated with 0.7 mL of OCT compound 469 (Tissue-Tek) mixed 1:1 v/v with 4% paraformaldehyde (Electron Microscopy Sciences) 470 diluted in PBS. Inflated lungs were snap-frozen and stored at -80°C until sectioning. 471 Tissue sections (4 µm) were stained with hematoxylin and eosin, and chronic lung 472 473 disease was scored on a scale of 0 to 3 for alveolitis, peribroncholitis and airway metaplasia. Percentage values and area affected was determined, multiplied by the 474 475 intensity scores previously defined, and the resulting weighted scores were graphed. For 476 immunostaining analysis, tissue sections were washed in PBS to remove OCT, and Fc 477 receptor blockade was performed using anti-mouse FcyRIII/II (FcBlock) (Jackson Immunoresearch) diluted 1:200 in PBS containing 1% bovine serum albumin (BSA). 478 Surface staining was performed using a panel of antibodies targeting T cells, B cells, 479 480 macrophages, and dendritic cells (**Supplementary Table 1**) at 4°C overnight. Sections were washed in PBS and surface antibodies were detected with anti-Rat AlexaFluor-488 481

482 secondary antibody (BioLegend). After surface staining, sections were permeabilized with 0.2% Saponin (Sigma) diluted in PBS containing 1% BSA and FcBlock (1:200), and 483 intracellular staining was performed using recombinant hu-mouse anti SeV-NP antibody 484 conjugated with AlexaFluor-647 (1:1000) (Invitrogen) in combination with either anti-Krt5 485 486 (1:500) (BioLegend) or anti-Krt8 (1:200) for 1 h at room temperature. Intracellular primary 487 antibodies were detected with anti-Rabbit AlexaFluor 488 or anti-Rat AlexaFluor 488 secondary antibodies. Nuclear staining was performed with Hoechst (Invitrogen) and 488 tissue autofluorescence was quenched using 1 x True Black (Biotium) diluted in 70% 489 490 ethanol. Slides were mounted with Fluormount-G (Invitrogen) and images were acquired using a Zeiss Axio observer Widefield fluorescence microscope, using 5x and 20x 491 492 objectives.

493

# 494 Fluorescence RNA *in situ* hybridization

RNA in situ hybridization was performed using RNAscope Multiplex Fluorescent Reagent 495 496 Kit v2 (Advanced Cell Diagnostics, Inc., Newark, NJ, USA) according to the 497 manufacturer's instructions. Lung sections (4 µm) were washed as described in the 498 previous paragraph and hybridized for 2 h at 40°C with the RNAscope probe V-SeV-NP-C1 (Cat. No. 1118511-C1) targeting the genomic RNA sequence of NP gene. 499 Preamplifier, amplifier, HRP-labeled oligos, and TSA plus (Cyanine3 or Cyanine5) (Akoya 500 501 biosciences) dye was then hybridized at 40°C. Nuclear staining was performed with DAPI, 502 and images were acquired as described in the previous sub-session.

503

# 504 Multicolor flow cytometry and cell sorting

505 At 3 and 49 dpi, mouse lungs were inflated with 0.7 mL of digestion mix containing collagenase A (Sigma), dispase (Thermofisher), liberase TL (Sigma) and DNAse I 506 (Sigma) and incubated at 37°C for 30 min with agitation. Digested samples were then 507 briefly vortexed and filtered through a 70-µm filter mesh to obtain single-cell suspensions. 508 The obtained cells were washed with PBS containing 5% FBS, treated with red blood 509 510 cells lysis buffer (Sigma), and total viable cells were quantified with trypan blue staining using an automated cell counter (TC-20 Automated Cell Counter; BioRad). For each 511 512 sample, 2x10<sup>6</sup> cells were resuspended in PBS supplemented with 1% BSA and 2 mM 513 EDTA (Corning). Next, Fc receptor blockade and viability staining were simultaneously performed using Rat anti-mouse FcyRIII/II (CD16/32; BD Biosciences) and ZombieNIR 514 515 (BioLegend) for 10 min at room temperature. To define major cell subpopulations (Fig 516 S1) we employed a panel of 16 antibodies (Table S1) to stain for surface markers. For 517 intracellular staining of Sendai virus NP, cells were fixed/permeabilized with the FoxP3/ 518 Transcription Factor Staining Buffer Set (eBioscience) following manufacturer's 519 guidelines, and incubated with recombinant hu-mouse anti-SeV NP antibody, conjugated with AlexaFluor-647 (Invitrogen) for 1h at 4°C. 520

To isolate specific lung cell populations with fluorescent activated cell sorting (FACS), surface staining was performed as mentioned above using a panel of lineagespecific markers (**Supplementary Table 1**). Live CD45<sup>+</sup>, Lineage<sup>-</sup>, Thy1.2<sup>+</sup> and sm13<sup>+</sup> cells were defined as ILC2s. Macrophages were obtained from the same single-cell suspensions mentioned above using the Anti-F4/80 MicroBeads UltraPure, mouse (Miltenyi Biotec) isolation kit. All flow cytometry experiments were performed using a Cytek Aurora spectral flow cytometer (Cytek Biosciences), with acquisition of at least

1x10<sup>6</sup> total events. FACS experiments were performed using a BD-FACS Aria-II. Data
analysis was done using FlowJo V12 software (Tree Star Inc.).

530

# 531 RNA-seq of sorted cells

For both ILC2 and macrophages obtained from SeV-infected sm13 mice, and for tdTom<sup>+</sup>, 532 tdTom<sup>+</sup>NP<sup>+</sup>, and negative cells obtained from rSeV-C<sup>eGFP-Cre</sup>-infected tdTom mice, total 533 RNA was extracted from at least three cell pools per condition, using KingFisher APEX 534 automated RNA Extraction and Purification system (ThermoFisher) according to the 535 536 manufacturer's guidelines. Each ILC2 and Macrophage sample, as well as tdTom<sup>+</sup>, tdTom<sup>+</sup>NP<sup>+</sup>, and negative cell samples was a resulting pool of cells from 2 individual 537 animals. Total cDNA libraries were prepared from 100 ng of starting RNA using TruSeq 538 539 Total RNA Library Prep Kit, with subsequent Ribo-Zero Human/Mouse/Rat Sample Prep Kit following manufacturer's instructions. Libraries were run on Illumina NovaSeg 6000 to 540 generate 150 bp, paired-end reads, resulting in 79-120 million reads per sample with an 541 542 average Phred score of 35.75.

543

#### 544 Viral reads and host transcriptome analysis

545 Sequencing adaptors were removed from the raw sequencing data using Cutadapt<sup>49</sup>. 546 Trimmed reads were then mapped to the mouse transcriptome (Ensembl release 79, 547 EnsDb.Mmusculus.v79) using Kallisto, with 60 boostraps per sample<sup>50</sup>. Subsequent 548 import and annotation of transcripts were done in R environment using the TxImport 549 package<sup>51</sup>. Differentially expressed genes (DEGs) (p value < 0.05, fold change > 2) 550 between pairwise comparisons were obtained by linear modeling and Bayesian statistics

using the VOOM function from the Limma package<sup>52</sup>. Gene Ontology (GO) analysis was 551 done using the enrichGO function from the ClusterProfiler package<sup>53</sup> with a p value cut-552 553 off of 0.05. Gene Set Enrichment Analysis (GSEA) was performed using the Molecular Signatures Database (MSigDB) msigdbr R package<sup>54</sup> including pathways found in the 554 C2, C5 and H Mus Musculus gene collections<sup>55,56</sup>. Finally, reads mapping the mouse 555 genome were removed from the trimmed dataset using Bowtie2 v2.4.1<sup>57</sup> and virus 556 coverage was obtained using SAMtools v1.15<sup>58</sup> after aligning the non-host reads to the 557 558 rSeV-C<sup>eGFP-Cre</sup> genome using Bowtie2. Virus coverage per sample was visualized using the ggplot2 R package<sup>59</sup>. All data analysis was performed in RStudio (v. 2023.06.0+421). 559

560

# 561 Statistical analysis

562 Statistical significance was inferred using GraphPad Prism software version 9.0 563 (GraphPad Software, San Diego, CA). For animal experiments, group size consisted of 564 3-7 mice per group. The weight-loss curve was analyzed by calculating the area under 565 the curve (AUC) from both groups and comparing them using student t-tests. One-way 566 and Two-way analysis of variance (ANOVA) with either Holm-Sídák or Bonferroni post-567 test was used to estimate the statistical significance between conditions of the remaining 568 experiments. P values <0.05 were considered significant.

569

# 570 Data deposition

571 Next generation sequencing raw data of SeV-52 and rSeV-C<sup>eGFP-Cre</sup> experiments 572 described in Figs 3, 4, and 5 was deposited in SRA under accession number 573 PRJNA1034107.

574

# 575 Acknowledgements

576 We thank J. Andrew Duty from the Center for Therapeutic Antibody Development, Drug 577 Discovery Institute, Icahn School of Medicine, Mount Sinai, New York, NY, USA for the technical support in the generation of the SeV humanized antibody used in this study. We 578 579 thank the Tissue Histology Core at the Center for Reproductive Health Sciences, Department of Obstetrics & Gynecology, Washington University School of Medicine, Saint 580 Louis, MO, USA for all the support with the tissue sectioning and histologic staining. We 581 582 also thank the Flow Cytometry & Fluorescent Activated Cell Sorting Core at the Department of Pathology & Immunology, Washington University School of Medicine, 583 584 Saint Louis, MO, USA for the help with the cell sorting experiments.

781 Figure 1. Viral antigens and RNA persist in mouse lungs after SeV-driven acute illness. A. Timeline of the study design. Mice were inoculated with either phosphate-782 buffered saline (mock) or 5x10<sup>4</sup> tissue culture infectious dose (TCID<sub>50</sub>) of SeV 52 per 783 784 animal. Lungs were analyzed on days 3 and 49 post-infection. **B.** Disease progression 785 was monitored by measuring weight loss through the experiment. Data are representative 786 of 4 independent experiments (mean ±SD). For SeV-infected and mock groups the area under the curve (AUC) was calculated and t-tests were performed for statistical 787 significance analysis. \*\*\*\*P<0.0001. C. Whole lung homogenates were harvested at days 788 789 3 and 49 post-infection and both SeV NP RNA expression and infectious virus titers were 790 quantified by qPCR and infectivity assays respectively. Relative RNA quantitation by 791 qPCR was normalized to mouse GAPDH and β-Actin. Two-way analysis of variance with 792 Holm-Sídák post-test was used to estimate statistical significance between groups. N = 5animals per group. \*P<0.05; \*\*P<0.01; \*\*\*\*P<0.0001. D. SeV-infected lungs were stained 793 794 for SeV NP (white staining, upper panels) using immunofluorescence and for SeV NP 795 RNA using RNAscope (white staining, lower panels). Nuclear staining (Hoechst for immunofluorescence and DAPI for RNAscope) in blue. Representative images of 3 796 797 independent experiments. Scale bars: 100 µm. E. SeV-infected lungs were stained for 798 basal stem cells (Krt5<sup>+</sup>, green staining) and SeV NP (magenta staining) to localize SeV NP<sup>+</sup> cells in relation to areas displaying chronic lesions (dashed areas, subpanels E1-E3) 799 800 and unaffected areas (subpanel E4). Arrowheads indicate SeV NP<sup>+</sup> cells, more detailed in the correspondent zoomed inset panels. Images were taken using a widefield 801 802 microscope. Left panel, tiling image, 5x magnification. Right subpanels, 20x magnification. Right insets: digital zooms from the correspondent 20x magnification 803

images. Scale bars: Left panel. 500 µm; Subpanels. 100 µm. Images are representative
of 3 independent experiments, 5 mice per group.

806

807 Figure 2. Diverse lung immune cells express SeV NP during chronic infection. A. Characterization of immune cells expressing SeV NP from cryopreserved mouse lungs 808 after 49 dpi by immunofluorescence. Tissue sections were stained for SeV NP (magenta) 809 in combination with the surface markers CD3 (T lymphocytes), CD11c, CD11b (dendritic 810 cell subsets), F4/80 (macrophages), and Thy1.2 (Innate Lymphoid Cells and some T 811 812 lymphocyte subsets) in green and red. Nuclear staining is displayed in blue. White arrows 813 indicate individual SeV NP<sup>+</sup> cells. Images were taken in a widefield fluorescence microscope using a 20x magnification scope. Scale bars: 25 µm. Representative images 814 815 from three independent experiments, 5 mice per condition. Right panels: insets from the 816 dashed areas. B-E. Lungs from SeV-infected mice were harvested at 3 and 49 dpi, 817 enzymatically digested, and analyzed by multiplex spectral flow cytometry with a panel of 818 16 antibodies to quantify (**B** and **C**) and characterize (**D** and **E**) SeV<sup>+</sup> cells. **B**. Representative dot plots of SeV NP<sup>+</sup> cells (% of live) comparing acute (3 dpi) with long-819 820 term (49 dpi) SeV infection. SeV NP<sup>+</sup> gates were drawn based on the isotype control and 821 the mock-infected samples. C. Frequency of SeV NP<sup>+</sup> cells gated on total live cells from SeV 3 days-, SeV 49 days-, and mock-infected lungs. D. Representative histograms of 822 823 SeV NP<sup>+</sup> fluorescence intensity from 9 individual cell subsets, B cells, ILC2s, T CD4<sup>+</sup> 824 lymphocytes, T CD8<sup>+</sup> lymphocytes, NK cells, Polymorphonuclear cells (PMNs), Alveolar macrophages (AMs), Tissue macrophages (TMs), and Dendritic cells (DCs) at 49 dpi. 825 826 Histograms from SeV-infected animals are displayed in red while histograms from mockinfected animals are displayed in gray. E. Frequency and mean fluorescence intensity
(MFI) of SeV NP<sup>+</sup> cells within lymphoid- and myeloid-origin cell subsets. All multiple
comparisons were done with one-way ANOVA and Holm-Sídák post-test. \*P<0.05;</li>
\*\*P<0.01; \*\*\*P<0.0005; \*\*\*\*P<0.0001. Data representative of two independent</li>
experiments, 4-5 animals per condition, total 1 million events acquired per animal.

832

Figure 3. Type 2 innate lymphoid cells and macrophages are persistently activated 833 834 in a type 2 inflammation manner during SeV chronic lung disease. Lung type 2 innate 835 lymphoid cells (ILC2s) (A-C), and macrophages (D-F) were isolated either from SeV- or 836 mock-infected mouse lungs after 49 dpi and subjected to bulk RNA-seq. A and D. Volcano 837 plots indicating differentially expressed genes detected in ILC2s and macrophages, respectively, from SeV-infected lungs over mock. P<0.05, LogFC>2. B-C. Scattered dot 838 839 plots showing expression of ILC2 hallmark genes (B) and virus-related ISGs (C). Each dot corresponds to an individual pool of cells (n = 6 animals pooled in pairs per condition). 840 841 **E-F.** Scattered dot plots indicating expression of Th2 polarization (E) and phagocytic 842 activity (F) genes from macrophages. Each dot corresponds to cells obtained from an 843 individual animal (minimum n = 3 animals per condition). Data are displayed as mean  $\pm$ SD. Two-way analysis of variance (ANOVA) with Bonferroni post-test was used to 844 estimate statistical significance between multiple comparisons. \*P<0.05; \*\*P<0.01; 845 846 \*\*\*\*P<0.0001. CPM, copies per million. G. Bubble chart showing gene set enrichment analysis (GSEA) of upregulated genes in ILC2s and macrophages sorted from SeV 49 847 848 dpi lungs. Bubble size indicates gene set size per GSEA pathway, while bubble color 849 gradient indicates Normalized Enrichment Scores (NES) values.

850

Figure 4. Paramyxovirus infection clearance is not complete and leaves long-term 851 852 survivor cells in the lower respiratory tract expressing persistent viral RNA and viral proteins. A. B6.Cg-Gt(ROSA)<sup>tdTom</sup> (tdTom) mice were inoculated intranasally with 853 either PBS (mock) or 5x10<sup>5</sup> TCID<sub>50</sub> rSeV-C<sup>eGFP-Cre</sup>. Lungs were harvested at 3, and 49 dpi 854 855 for flow cytometry (FC) analysis, and cell sorting at 49 dpi. Weight loss was recorded up to 21 dpi to monitor disease progression. Data (mean±SD) are representative of 2 856 857 individual experiments (minimum 3 mice per group). B. Representative dot plots 858 comparing percentage of tdTom<sup>+</sup> cells in mouse lungs during acute (3 dpi) and chronic (49 dpi) rSeV- C<sup>eGFP-Cre</sup> infection. **C.** Frequency of tdTom<sup>+</sup> cells gated on total live cells 859 from rSeV-C<sup>eGFP-Cre</sup> 3 days-, rSeV- C<sup>eGFP-Cre</sup> 49 days-, and mock-infected lungs. Data are 860 861 shown as mean±SD. Statistical significance was estimated with one-way ANOVA using Bonferroni post-test. \*\*\*P<0.005. D-E. Characterization of immune (CD45<sup>+</sup>) and non-862 immune (CD45<sup>-</sup>) cell proportions within tdTom<sup>+</sup> cells. Representative dot plots (**D**) and 863 864 quantification (E) of CD45 staining in tdTom<sup>+</sup> cells during acute (3 dpi) and chronic (49 dpi) rSeV-C eGFP-Cre infection. Statistical significance was estimated with two-way ANOVA 865 866 and Holm-Sídák post-test. \*P<0.05. F. Combination of tdTom and SeV NP detection enables sorting of two distinct subsets of VID cells, SeV-infected cells persistently 867 expressing viral antigens (tdTom<sup>+</sup>NP<sup>+</sup>) and SeV-infected/survivor cells only (tdTom<sup>+</sup>NP<sup>-</sup>). 868 869 Representative dot plots indicating the gating strategy used for sorting 3 cell subpopulations from rSeV-C<sup>eGFP-Cre</sup>-infected lungs tdTom<sup>+</sup>NP<sup>-</sup>, tdTom<sup>+</sup>NP<sup>+</sup>, and negative. 870 871 Negative cells from mock-infected lungs were also sorted. Data representative of 2 872 individual experiments, 6 mice per condition. G. Sorted cells were pooled (2 mice) and

subjected to RNAseq. Normalized viral reads per 10<sup>8</sup> total reads are displayed per
individual pool of tdTom<sup>+</sup>NP<sup>-</sup> and tdTom<sup>+</sup>NP<sup>+</sup> cells. H. Coverage analysis indicating
normalized viral reads per genome position in each individual cell pool. Viral specific gene
regions and reporter genes are indicated in light gray.

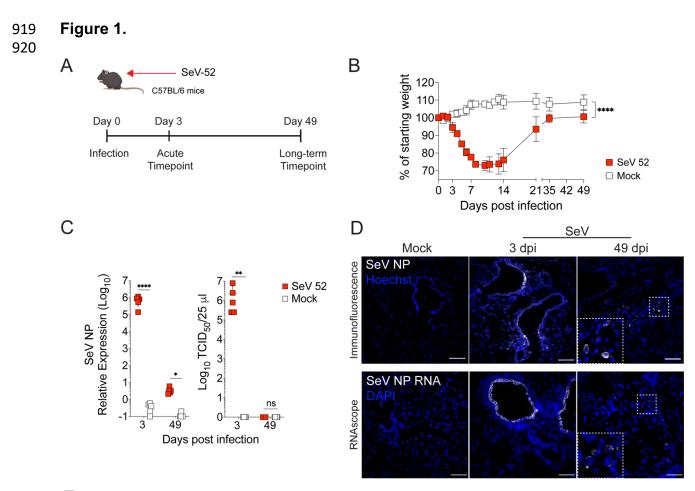

877

Figure 5. Viral clearance and persistence entails opposing transcriptional 878 programs in long-term SeV-infected lungs. Viral infected and cells derived from them 879 sorted from tdTom mice infected with rSeV-C<sup>eGFPCre</sup> at 49 dpi were subjected to bulk 880 881 RNAseg and host transcriptome analysis. A. Volcano plots indicating differentially 882 expressed genes (DEGs) in tdTom<sup>+</sup>NP<sup>-</sup>, tdTom<sup>+</sup>NP<sup>+</sup>, and Negative cells against Mock negative cells. **B.** Venn diagram showing overlapping DEGs from tdTom<sup>+</sup>NP<sup>-</sup> and 883 884 tdTom<sup>+</sup>NP<sup>+</sup>, as well as exclusive DEGs from each cell subset. **C.** Bar graphs showing gene ontology (GO) enrichment analysis of each of the VID cell subsets (tdTom<sup>+</sup>NP<sup>-</sup> and 885 tdTom<sup>+</sup>NP<sup>+</sup>) exclusive DEGs. **D.** Heatmaps of selected gene collections from the GO 886 887 pathways in **C**. Shown are fold change (FC) values of tdTom<sup>+</sup>NP<sup>-</sup> and tdTom<sup>+</sup>NP<sup>-</sup> are displayed. Columns groups are color-coded following the same patterns on C. and B. E. 888 889 Gene set enrichment assay (GSEA) bubble chart indicating the most significant enriched pathways of tdTom<sup>+</sup>NP<sup>+</sup> transcriptome signatures in comparison with tdTom<sup>+</sup>NP<sup>-</sup> cells. 890 891 Bubble color gradient indicates Normalized enrichment score (NES), and bubble sizes 892 correspond to gene set size on each pathway.

893

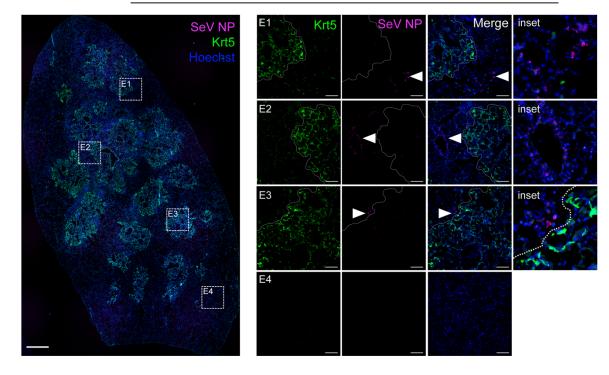

Figure 6. Chronic lung pathology induced by paramyxovirus infection is dependent
 on long-term surviving and persistently infected cells. A. Diphtheria toxin regime

896 treatment and timepoints for tissue harvesting and analysis. B. Disease progression was assessed by monitoring animal weight loss until 26 dpi. Graphs are representative of 2 897 independent experiments and depict mean weight loss values ±SD, 4 mice per condition. 898 899 C. Mouse lungs were harvested at 49 dpi and tissue sections were stained with 900 Hematoxylin and Eosin to compare pathological changes between the analysis groups. 901 Top panels indicate representative images of whole lung sections (Brightfield, 5x magnification tiled images, Scale bars: 1 mm) and bottom panels indicate zoomed-in 902 images from the indicated areas (Brightfield, 5x magnification tiled images, scale bars: 903 904 100 µm). 4 animals per condition. **D.** Lung sections from SeV +DT and SeV -DT groups 905 were blindly scored for histopathological changes. Total area affected, percentage of 906 airway structures affected, and intensity of alveolitis, peribroncholitis, and bronchus-907 associated lymphoid tissue (BALT) expansion were determined for every individual lung sample. Individual weighted scores values ±SD are indicated. Data representative of 2 908 909 individual experiments, 4-7 mice per condition. E. Lung sections were stained for the 910 tissue remodeling and chronic lung lesion markers Krt5 (green) and Krt8 (magenta) with 911 immunofluorescence to check for chronic lung lesion progression. Nuclear staining is 912 displayed in blue. The dashed area indicates chronic lung lesions and areas of intense 913 tissue remodeling. Images were taken with a widefield microscope. Upper panels, tiling 914 images, 20x magnification, scale bars: 500 µm. Lower panels: 20x magnification, scale 915 bars: 100 µm. F. Quantification of chronic lung lesion area (%) over total lung section 916 area. Mean values ±SD are shown. Data are representative of two individual experiments, 917 4-7 mice per condition. Statistical significance was estimated using one-way ANOVA and Bonferroni post-test. \*P<0.05. 918

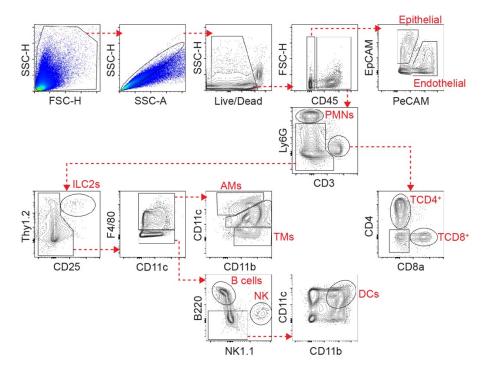

Figure S1. Gating strategy for spectral flow cytometry analysis of SeV-infected lungs. Representative dot plots indicating the following cell subsets defined from live cells: Epithelial cells (CD45<sup>-</sup>EpCAM<sup>+</sup>PeCAM<sup>-</sup>), Endothelial cells (CD45<sup>-</sup>EpCAM<sup>-</sup>PeCAM<sup>+</sup>), Polymorphonuclear cells (PMNs) (CD45<sup>+</sup>Ly6G<sup>+</sup>CD3<sup>-</sup>), T CD4<sup>+</sup> lymphocytes (CD45<sup>+</sup>Ly6G<sup>-</sup>CD3<sup>+</sup>CD4<sup>+</sup>CD8a<sup>-</sup>), T CD8<sup>+</sup> lymphocytes (CD45<sup>+</sup>Ly6G<sup>-</sup>CD3<sup>+</sup>CD4<sup>-</sup>CD8a<sup>+</sup>), Type 2 innate lymphoid cells (ILC2s) (CD45<sup>+</sup>Ly6G<sup>-</sup> CD3<sup>-</sup>Thy1.2<sup>+</sup>CD25<sup>+</sup>), Alveolar macrophages (AMs) (CD45<sup>+</sup>Ly6G<sup>-</sup>CD3<sup>-</sup>F4/80<sup>+</sup>CD11c<sup>hi</sup>CD11b<sup>low</sup>), Tissue macrophages (TMs) (CD45<sup>+</sup>Ly6G<sup>-</sup>CD3<sup>-</sup>F4/80<sup>+</sup>CD11c<sup>low</sup>CD11b<sup>hi</sup>), B cells (CD45<sup>+</sup>Ly6G<sup>-</sup> CD3<sup>-</sup>F4/80<sup>-</sup>B220<sup>hi</sup>), Natural killer cells (NK) (CD45<sup>+</sup>Ly6G<sup>-</sup>CD3<sup>-</sup>F4/80<sup>-</sup>B220<sup>-</sup>NK1.1<sup>hi</sup>), Dendritic cells (DCs) (CD45<sup>+</sup>Ly6G<sup>-</sup>CD3<sup>-</sup>F4/80<sup>-</sup>B220<sup>-</sup>NK1.1<sup>-</sup>CD11c<sup>hi</sup>CD11b<sup>hi</sup>). 

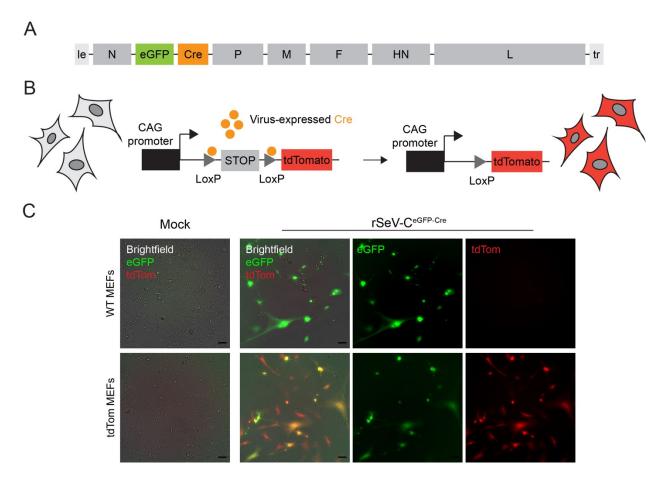

Figure S2. Generation of a Cre-expressing recombinant Sendai virus. A. Genome schematics showing the insertion of eGFP and the recombinase Cre genes as independent reading frames in the SeV Cantell genome, between the virus genes N and P, to generate a Cre-expressing SeV recombinant virus (rSeV-C<sup>eGFPCre</sup>). B. Schematic design showing Cre recombination of the LoxP-STOP-tdTomato reporter gene cassette leading to constitutive expression of the tdTomato fluorescent protein. C. Murine embryonic fibroblasts (MEFs) from either WT C57BL/6 mice or tdTomato reporter mice were infected in vitro at a multiplicity of infection (MOI) of 0.01 TCID<sub>50</sub>/cell to test the robustness of the reporter system. Representative images from two independent experiments were taken after 24 hpi using a widefield fluorescence microscope. eGFP signal (green) and tdTomato signal (red) were overlaid on brightfield images of WT and tdTomato-infected MEFs. 20x magnification. Scale bars: 50 µm.

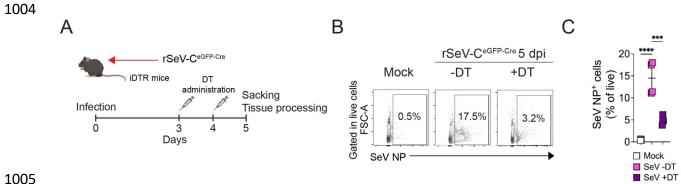

Figure S3. Diphtheria toxin administration efficiently depletes SeV infected cells. A. Experimental design showing diphtheria toxin (DT) regime treatment and timepoints for tissue harvesting and analysis. B. Representative dot plots of rSeV-C eGFP-Cre -infected lungs analyzed by flow cytometry for SeV NP expression. 50,000 events acquired. C. Quantification of SeV NP<sup>+</sup> cell frequency (% of live) detected by flow cytometry at 5 dpi. Mean values ±SD are displayed. data are representative of 2 individual experiments, 4-5 mice per group. One way ANOVA with Bonferroni post-test was used to estimate statistical significance between groups. \*\*\*P<0.0005. \*\*\*\*P<0.0001.

anti-mouse CD3 biotin-conjugated	Biolegend	309806
anti-mouse CD4 biotin-conjugated	Biolegend	100244
anti-mouse CD8a biotin-conjugated	Biolegend	100244
anti-mouse/human CD11b biotin-conjugated	Biolegend	11704
anti-mouse Ly6G/Ly6C (Gr-1) biotin-conjugated	Biolegend	101204
anti-mouse NK1.1 biotin-conjugated	Biolegend	101204
anti-mouse CD49b (Pan-NK) biotin-conjugated	Biolegend	108403
anti-mouse CD19 biotin-conjugated	Biolegend	108704
	<u> </u>	115504
anti-mouse Ter-119 (Erythroid cells) biotin-conjugated anti-mouse CD11c biotin-conjugated	Biolegend	116203
	Biolegend	
anti-mouse TCR gamma/delta biotin-conjugated	Biolegend	117304
anti-mouse CD170 (Siglec-F) biotin-conjugated	Biolegend	118103
anti-mouse CD90.2 (Thy1.2) Antibody biotin-conjugated	Biolegend	155512
anti-human CD4 Antibody biotin-conjugated	Biolegend	140314
Goat Anti-Rabbit AlexaFluor488 Secondary antibody	Invitrogen	A-11008
Anti-Rat AlexaFluor488 Secondary antibody	Biolegend	405418
Goat Anti-Rat AlexaFluor647 Secondary antibody	Invitrogen	A-21247
Commercial assays		
RNAscope® Multiplex Fluorescent Detection Kit v2	ACD	323110
RNAscope® Target Retrieval Reagents	ACD	322000
RNAscope® 2.5 HD Detection Reagents-BROWN	ACD	322310
TSA Plus Fluorescein Kit 50-150 slides	Akoya biosciences	NEL741001KT
TSA Plus Cyanine 3 Kit 50-150 slides	Akoya biosciences	NEL744001KT
TSA Plus Cyanine 5 Kit 50-150 slides	Akoya biosciences	NEL745001KT
Power SYBR™Green PCR Master Mix	ThermoFisher	4367660
High Capacity cDNA Reverse Transcription Kit	Applied Biosystems	4368813

Zombie NIR™ Fixable Viability Kit	Biolegend	423106	
AlexaFluor 647 Antibody Labeling kit	ThermoFisher	A20186	
General reagents			
BSA	Sigma	A3059-100G	
TPCK-treated Trypsin	Worthington Biochem.	#LS003750	
	Corporation		
EDTA	Corning	46-034-CI	
DNAse I (for molecular biology)	ThermoScientific	#EN0252	
Paraformaldehyde (PFA)	Electron Microscopy	15714-5	
	Sciences		
Saponin	Sigma	47036-50G-F	
Collagenase A	Sigma	10103586001	
Dispase	Gibco	17105-041	
Liberase TL	Sigma	5401020001	
DNAse I (for tissue digestion)	Sigma	10104159001
