Abstract

Objective To investigate the view of clinicians on diagnostic radiology and its future.

Methods Corresponding authors who published in the *New England Journal of Medicine* and the *Lancet* between 2010 and 2022 were asked to participate in a survey about diagnostic radiology and its future.

Results The 331 participating clinicians gave a median score of 9 on a 0–10 point scale to the value of medical imaging in improving patient-relevant outcomes. 40.6%, 15.1%, 18.9%, and 9.5% of clinicians indicated to interpret more than half of radiography, ultrasonography, CT, and MRI examinations completely by themselves, without consulting a radiologist or reading the radiology report. Two hundred eighty-nine clinicians (87.3%) expected an increase in medical imaging utilization in the coming 10 years, whereas 9 clinicians (2.7%) expected a decrease. The need for diagnostic radiologists in the coming 10 years was expected to increase by 162 clinicians (48.9%), to remain stable by 85 clinicians (25.7%), and to decrease by 47 clinicians (14.2%). Two hundred clinicians (60.4%) expected that artificial intelligence (AI) will not make diagnostic radiologists redundant in the coming 10 years, whereas 54 clinicians (16.3%) thought the opposite.

Conclusion Clinicians who published in the *New England Journal of Medicine* or the *Lancet* attribute high value to medical imaging. They generally need radiologists for cross-sectional imaging interpretation, but for a considerable proportion of radiographs, their service is not required. Most expect medical imaging utilization and the need for diagnostic radiologists to increase in the foreseeable future, and do not expect AI to make radiologists redundant.

Clinical relevance statement The views of clinicians on radiology and its future may be used to determine how radiology should be practiced and be further developed.

Key Points

- Clinicians generally regard medical imaging as high-value care and expect to use more medical imaging in the future.
- Clinicians mainly need radiologists for cross-sectional imaging interpretation while they interpret a substantial proportion of radiographs completely by themselves.
- The majority of clinicians expects that the need for diagnostic radiologists will not decrease (half of them even expect that we need more) and does not believe that AI will replace radiologists.

Introduction

Diagnostic radiology has evolved tremendously over the past decades. Diagnostic accuracy has improved owing to the advent of cross-sectional imaging techniques, imaging volumes have increased, and radiologists are increasingly involved in multidisciplinary clinical decision-making [1–3]. Meanwhile, concepts such as precision medicine and value-based healthcare have been introduced to reform

clinical practice [4, 5], and radiology leaders have put forward potential strategies to accommodate them [6, 7]. However, major challenges that still need to be addressed in the present and the foreseeable future are the escalating healthcare costs and the increasing workload of radiologists due to the ever-rising demand for medical imaging services [2, 8–10].

Cuts in healthcare reimbursements for radiological procedures and an unwillingness to train more radiologists conflict with the projected increase in radiology workload. Introducing artificial intelligence (AI) tools in radiology has been proposed as a potential solution to aid efficiency, ease workload, and perhaps even replace radiologists [11–14]. However, widespread implementation of AI has not been realized yet in routine practice. Consequently, policymakers may be unsure about how diagnostic radiology will develop in the future in terms of required investments and workforce. Policymakers may also wonder if medical imaging adds value to healthcare [5], and if it is worthwhile to be invested in. Because of these unresolved issues and tight budgets, investments in radiology are not infrequently stalled.

Radiologists work in close collaboration with clinicians in providing healthcare services to patients. Currently, there is a lack of literature on how clinicians view radiology and its future with respect to required services, whether or not these services add value, and the role of AI in the profession. This information plays a crucial role in how radiology should be practiced and can be prepared for the future.

The purpose of this study was therefore to investigate the view of clinicians on diagnostic radiology and its future.

Materials and methods

Study participants

This survey study was approved by the institutional review board of the University Medical Center Groningen. The *New England Journal of Medicine* and the *Lancet* are regarded as the prime journals for publishing studies that have a major impact on clinical practice. All corresponding authors of articles that were published in these two journals between January 2010 and September 2022 were sent an invitation to participate in a survey about the value and future of radiology. The e-mail address of the corresponding author that was provided in each article was used for this purpose. Survey participants without a medical doctor (MD) degree and those with radiology and/or nuclear medicine as medical specialty were excluded. The first invitations for survey participation were sent on 28 September 2022, and reminders were sent on 12 October, 26 October, 16 November, and 30 November 2022.

Survey

The survey contained 18 closed-ended questions, with 9 questions capturing information on respondents' basic characteristics (age, gender, type of workplace, country of work, possession of an MD degree, years of experience as an MD, medical specialty qualification, and current number of weekly working days in clinical practice), 5 questions on which diagnostic radiology examinations are requested by the respondents and by whom these are interpreted, and 4 questions on the value of medical imaging utilization and expected future developments (Table 1). Finally, the survey participants were given the opportunity to leave any comments in a free text field. The digital survey was built with Qualtrics Core XM survey software (Qualtrics LLC) and access was provided through a weblink. Participation was on an anonymous basis.

Data analysis

Basic characteristics of the respondents, their opinion on the value of medical imaging, their habits towards requesting and interpreting diagnostic radiology examinations, and expected future developments were descriptively summarized. Multivariate regression analyses were performed to determine the association between clinicians' dependency on radiologists in interpreting diagnostic radiology examinations (according to questions 11–14 as shown in Table 1) with the type of clinician (academic vs. non-academic hospital employment, medical specialist vs. non-medical specialist status, and surgical specialty vs. non-surgical specialty) and continent of work (Africa, Asia, Australia, Europe, North America, or South America). Note that cardiothoracic surgery, neurosurgery, obstetrics and gynecology, ophthalmology, oral and maxillofacial surgery, orthopedics, otorhinolaryngology, plastic surgery, general, oncologic, pediatric, transplant, and vascular surgery, and urology were predefined as surgical specialties, and all other specialties were regarded as non-surgical specialties, as also indicated in Table 2. Clinicians with both a surgical and a non-surgical specialty were included in the surgical specialty group. Multivariate regression analyses were also performed to determine the associations between the value attributed to medical imaging, projected medical imaging utilization, radiologist workforce requirement, and role of AI, with the clinician's characteristics (age, gender, academic vs. non-academic hospital employment, continent of work, medical specialist vs. non-medical specialist status, surgical specialty vs. non-surgical specialty, years of clinical experience as MD). *p*-values less than 0.05 were considered statistically significant. Statistical analyses were executed using IBM Statistical Package for the Social Sciences (SPSS) version 23. The comments provided by the respondents in the free text field at the end of the survey were jointly analyzed

Table 1 Survey questions and answer options

No	Question	Answer options
1	How old are you?	< 18, 18–24, 25–34, 35–44, 45–54, 55–64, or > 65 years old
2	What is your gender?	Male, female, or other
3	Where do you currently work or have you most recently worked?*	Academic hospital, non-academic hospital, non-hospital healthcare setting, other
4	In which country do you work or have you most recently worked?*	List of 30 countries, and open text field to indicate another country not listed
5	Are you a medical doctor?	Yes or no
6	How many years of experience do you have as a medical doctor?	< 5, 5–10, or > 10 years
7	Are you a medical specialist?	Yes or no
8	What is your medical specialty?*	List of 38 medical specialties, and open text field to indicate another medical specialty not listed
9	How many days per week do you currently work in clinical practice?	0, 1, 2, 3, 4, 5, 6, or 7
10	What type(s) of diagnostic radiology examinations do you request in clinical practice?*	None, plain radiography, ultrasonography, CT, MRI
11	How many of your plain radiographs do you interpret completely by yourself, without consulting a radiologist or reading his/her report?	None, 1–25%, 26–50%, 51–75%, 76–99%, or 100%
12	How many of your ultrasonography examinations do you perform and interpret completely by yourself, without consulting a radiologist or reading his/her report?	None, 1–25%, 26–50%, 51–75%, 76–99%, or 100%
13	How many of your CT examinations do you interpret completely by yourself, without consulting a radiologist or reading his/her report?	None, 1–25%, 26–50%, 51–75%, 76–99%, or 100%
14	How many of your MRI examinations do you interpret completely by yourself, without consulting a radiologist or reading his/her report?	None, 1–25%, 26–50%, 51–75%, 76–99%, or 100%
15	In your opinion, how much does medical imaging contribute to improving patient-relevant outcomes?	0–10 point linear scale, with 0 indicating nothing and 10 indicating very much
16	Do you expect that medical imaging utilization will increase in the coming 10 years?	Yes, no, or undecided
17	Do you expect that we need more or less diagnostic radiologists in the coming 10 years?	More, neither more nor less, less, or undecided
18	Do you expect that artificial intelligence will make diagnostic radiologists redundant in the coming 10 years?	Yes, no, or undecided

by the authors (T.C.K., M.T.A., and R.M.K.) to identify the most common topics that were put forward.

Results

Characteristics of eligible participants

A total of 393 persons participated. Of these 393 respondents, 37 were excluded because they did not have an MD degree and 25 were excluded because radiology and/or nuclear medicine was their medical specialty. Therefore, 331 clinicians were finally included. Most clinicians were aged 55–64 years (26.9%), were male (74.3%), worked in an academic hospital (81.9%), worked in the USA (19.3%), were a medical specialist (92.7%), had a non-surgical specialty (82.8%), had > 10 years of clinical experience as

MD (87.3%), and indicated to work in clinical practice 5 days per week (35.3%) (Table 2). A total of 296 clinicians (89.4%) indicated to request diagnostic radiology examinations in clinical practice, of whom 235 (79.4%) request radiography, 253 (85.5%) request ultrasonography, 270 (91.2%) request CT, and 258 (87.2%) request MRI.

Value attributed to medical imaging

Clinicians gave a median score of 9 (interquartile range [IQR]: 8–10; range: 1–10) on a 0–10 point scale to the value of medical imaging in improving patient-relevant outcomes. Australia as the continent of work was significantly associated with lower scores (β coefficient of -1.132 , 95% confidence interval [CI]: -2.026 to -0.238 , $p = 0.013$) than Europe as the continent of work.

Dependency of clinicians on radiologists: radiography

40.6% of clinicians indicated to interpret more than half of radiographs completely by themselves (i.e., without consulting a radiologist or reading the radiology report). In addition, 9.0% reported to never consult a radiologist or read a radiology report for the interpretation of a radiograph (Table 3). Clinicians working in surgical specialties (β coefficient of 1.238, 95% CI: 0.602 to 1.875, $p < 0.001$) and clinicians working in Asia (β coefficient of 1.304, 95% CI: 0.506 to 2.101, $p = 0.001$) were significantly less dependent on radiologists in interpreting radiographs than those working in non-surgical specialties and those working in Europe.

Dependency of clinicians on radiologists: ultrasonography

15.1% of clinicians indicated to interpret more than half of ultrasonography examinations completely by themselves. In addition, 7.5% reported to interpret ultrasonography always completely by themselves (Table 3). Clinicians working in surgical specialties (β coefficient of 0.574,

95% CI: 0.060–1.088, $p < 0.001$) were significantly less dependent on radiologists in interpreting ultrasonography than those working in non-surgical specialties. On the other hand, clinicians working in a non-academic hospital (β coefficient of -1.297 , 95% CI: -2.258 to -0.337 , $p = 0.008$) and clinicians working in North America (β coefficient of -0.618 , 95% CI: -1.115 to -0.121 , $P = 0.015$) were significantly more dependent on radiologists in interpreting ultrasonography than those working in academic hospitals and those working in Europe.

Dependency of clinicians on radiologists: CT

18.9% of clinicians indicated to interpret more than half of CT scans completely by themselves. In addition, 3.4% reported to interpret CT always completely by themselves (Table 3). Clinicians working in a surgical specialty (β coefficient of 0.800, 95% CI: 0.293–1.307, $p = 0.002$) and clinicians working in Asia (β coefficient of 0.785, 95% CI: 0.115–1.455, $p = 0.022$) or South America (β coefficient of 1.339, 95% CI: 0.158–2.520, $p = 0.026$) were significantly less dependent on radiologists in interpreting CT than those

Table 3 Percentages of clinicians (with absolute numbers between parentheses) who indicated which proportion of diagnostic radiology examinations they interpret completely by themselves, without consultation of a radiologist or reading the radiology report

Proportion completely self-interpreted examinations	Radiography ^a	Ultrasonography ^a	CT ^b	MRI ^b
None	26.5% (n = 62)	62.7% (n = 158)	57.4% (n = 152)	67.2% (n = 170)
1–25%	23.5% (n = 55)	13.5% (n = 34)	15.1% (n = 40)	15.8% (n = 40)
26–50%	9.4% (n = 22)	5.2% (n = 13)	8.7% (n = 23)	7.5% (n = 19)
51–75%	9.8% (n = 23)	3.6% (n = 9)	8.7% (n = 23)	5.9% (n = 15)
76–99%	21.8% (n = 51)	4.0% (n = 10)	6.8% (n = 18)	2.4% (n = 6)

^aNot filled in by 1 respondent^bNot filled in by 5 respondents

working in non-surgical specialties and those working in Europe.

Dependency of clinicians on radiologists: MRI

9.5% of clinicians indicated to interpret more than half of MRI scans completely by themselves. In addition, 1.2% reported to interpret MRI always completely by themselves (Table 3). Clinicians working in Asia (β coefficient of 0.732, 95% CI: 0.048–1.415, $p = 0.036$) were significantly less dependent on radiologists in interpreting MRI than those working in Europe.

Projected medical imaging utilization

Medical imaging utilization was expected to increase in the coming 10 years by 289 clinicians (87.3%) and to decrease by 9 clinicians (2.7%), while 33 clinicians (10.0%) remained undecided. None of the clinicians' characteristics showed any significant association with the projected medical imaging utilization.

Projected radiologist workforce requirement

The need for diagnostic radiologists in the coming 10 years was expected to increase by 162 clinicians (48.9%), to remain stable by 85 clinicians (25.7%), and to decrease by 47 clinicians (14.2%), while 37 clinicians (11.2%) remained undecided. Clinicians aged > 65 years expected less diagnostic radiologists to be necessary (β coefficient of -0.704 , 95% CI: -1.397 to -0.011 , $p = 0.046$) than clinicians aged 55–64 years.

Projected impact of AI on the need for diagnostic radiologists

Two hundred clinicians (60.4%) did not expect AI to make diagnostic radiologists redundant in the coming 10 years and 54 clinicians (16.3%) thought the opposite, while 77 clinicians (23.3%) remained undecided. Female clinicians were significantly less likely to expect that AI would make diagnostic radiologists redundant (odds ratio of 0.331, 95% CI: 0.123 to 0.891, $p = 0.029$) than male clinicians.

Qualitative analysis narrative comments

Most of the 121 clinicians who provided narrative comments at the end of the survey indicated that radiologists will remain necessary in the foreseeable future and that AI may potentially support them in doing their work (particularly for narrow task-specific applications), but that AI is unlikely to replace radiologists (Supplementary Table 1). Many clinicians postulated that AI will be unable to take over human problem solving and to deal with complex or uncommon cases (Supplementary Table 1).

Discussion

The results of this study indicate that clinicians generally regard medical imaging as very high-value care. Clinicians working in the continent of Australia tended to assign slightly lower grades to the value of medical imaging, but it remains unclear why this was the case.

Our results also indicate that clinicians need radiologists more for cross-sectional imaging than radiography interpretation. In fact, a substantial proportion of radiographs appears to be interpreted completely independently by clinicians without consultation of a radiologist or reading the radiology report. Clinicians working in surgical specialties were significantly less dependent on radiologists in interpreting radiography, ultrasonography, and CT than those working in non-surgical specialties, which may be explained by a greater anatomical knowledge. However, this was not the case for MRI, which is probably due to the more complex physical principles of MRI that need to be understood for image interpretation. Our study also found intercontinental differences in clinicians' dependency on radiologists in interpreting medical imaging examinations, which may reflect differences in the availability of radiologists and medical imaging skills of clinicians in the various continents. Clinicians working in a non-academic hospital also tended to be more dependent on radiologists for ultrasonography interpretation than those working in an academic hospital. The reason for this observation remains unclear.

Clinicians expected that the use of medical imaging will further increase in the coming 10 years. Almost half of clinicians also expected that more diagnostic radiologists are needed, although those aged > 65 years tended to indicate that less diagnostic radiologists are required. Perhaps retired clinicians are less well informed about the latest developments in imaging technology and applications, which may explain their view on this topic. Most clinicians think that AI will not make diagnostic radiologists redundant in the next 10 years. In fact, most believe AI cannot replace radiologists, and that it can only be used as a support for narrow task-specific applications. Female clinicians were more likely to believe that AI would not replace radiologists, for which we do not have a clear explanation.

Low-value care has been defined as care that confers no benefit or benefit that is disproportionately low compared with its cost [15]. Imaging and other diagnostic studies were described as low-value services in a recent *New England Journal of Medicine* article [16], and it has been estimated that 20–50% of all radiological examinations are of low value [17]. Previous articles have discussed how value may potentially be improved in radiology and how a waste of healthcare resources can be minimized [18, 19]. However, our results indicate that clinicians generally regard medical imaging as crucial for improving patient-relevant outcomes and that their number of medical imaging requests will increase in the future. These findings may perhaps convince policymakers that it is necessary to invest in medical imaging.

Previous studies have shown that around 10–20% of radiology reports are not read by clinicians [20, 21]. Previous

work also indicated that radiography reports are less frequently read than cross-sectional imaging reports [20]. In a study among 81 orthopedic surgeons working in hospitals in German-speaking regions of Europe, radiography, CT, and MRI reports were routinely viewed by 43%, 67% and 86%, and were never viewed by 20%, 4%, and 0%, respectively [22]. In another study among 200 orthopedic surgeons in Australia and New Zealand, reports for radiography, ultrasonography CT, and MRI were read by 10%, 74%, 35%, and 92%, respectively [23]. The results of these previous studies resonate with ours, and may trigger policymakers to reconsider if radiologists should report all diagnostic examinations (particularly radiographs) or limit their time and energy to examinations for which their assistance is really needed (particularly cross-sectional imaging). Implementing such a reform in clinical routine could save valuable healthcare resources and increase the value of diagnostic radiologists.

In the past, an increase in the demand for medical imaging services would simply imply that the number of diagnostic radiologists also had to increase to compensate for the increased workload [24]. However, AI is considered as a disruptive technology whose impact on the required workforce of diagnostic radiologists still remains unclear [25]. In a study from 2018, 56 surgeons in Switzerland were asked their opinion about the role of radiologists and the future of radiology [26]. The surgeons in that survey were somewhat equivocal as to whether or not the required workforce of diagnostic radiologists will change and how it will be affected by AI [26]. In the present study, however, clinicians generally tended to predict a need for more radiologists in the coming 10 years and did not expect AI to replace radiologists. This difference may be explained by the fact that the present study included a larger and more representative group of clinicians, including those with a non-surgical specialty. In addition, clinicians' knowledge about the possibilities and limitations of AI may have evolved in the past few years. These projected workforce requirements may be informative to policymakers who decide about the number of radiology residents that should be trained and how many financial resources should be allocated to employ (new) radiologists.

The present study had some limitations. First, this study was limited to corresponding authors who published in the *New England Journal of Medicine* or the *Lancet*, and predominantly included clinicians working in an academic hospital. Second, this study provided an understanding of clinicians' current view on some important aspects of diagnostic radiology, but this may change in the near future. Third, although our study showed that clinicians interpret a considerable proportion of imaging examinations completely by themselves (i.e., without consulting a radiologist or reading the radiology report), it remains to be further investigated to

which specific clinical settings this practice applies. Fourth, clinicians were asked whether they requested plain radiography, ultrasonography, CT, and MRI examinations in their practice and which proportion of these examinations were completely interpreted by themselves. However, plain radiography, ultrasonography, CT, and MRI are imaging modalities and not specific types of images. Breast imaging, for example, was not addressed. Furthermore, this study did not specifically investigate the clinicians' view on the value and future of nuclear medicine imaging. These topics should be investigated by future studies. Fifth, the survey was not formally validated prior to using for the present study, and the qualitative analysis was not done using a formal model and process.

In conclusion, clinicians who published in the *New England Journal of Medicine* or the *Lancet* attribute high value to medical imaging. They generally need radiologists for cross-sectional imaging interpretation, but for a considerable proportion of radiographs, their service is not required. Most expect medical imaging utilization and the need for diagnostic radiologists to increase in the foreseeable future, and do not expect AI to make radiologists redundant.

Declarations

Guarantor The scientific guarantor of this publication is Thomas C. Kwee.

Conflict of interest The authors of this manuscript declare no relationships with any companies, whose products or services may be related to the subject matter of the article.

Statistics and biometry No complex statistical methods were necessary for this paper.

Informed consent Written informed consent was obtained from all participants.

Ethical approval Local institutional review board approval was obtained.

Study subjects or cohorts overlap None of the study subjects has been reported previously.

Methodology

- not applicable
- experimental
- performed at one institution
