SUMMARY

Mowat-Wilson syndrome is caused by mutations in ZEB2, with patients exhibiting characteristics indicative of neural crest (NC) defects. We examined the contribution of ZEB2 to human NC formation using a model based on human embryonic stem cells. We found ZEB2 to be one of the earliest factors expressed in prospective human NC, and knockdown revealed a role for ZEB2 in establishing the NC state while repressing pre-placodal and non-neural ectoderm genes. Examination of ZEB2 N-terminal mutant NC cells demonstrates its requirement for the repression of enhancers in the NC gene network and proper NC cell terminal differentiation into osteoblasts and peripheral neurons and neuroglia. This ZEB2 mutation causes early misexpression of BMP signaling ligands, which can be rescued by the attenuation of BMP. Our findings suggest that ZEB2 regulates early human NC specification by modulating proper BMP signaling and further elaborate the molecular defects underlying Mowat-Wilson syndrome.

INTRODUCTION

The neural crest (NC) is a multipotent cell population unique to vertebrates that migrates extensively and contributes to many cell types in the developing embryo ([Douarin and Kalcheim, 1999\)](#page-11-0). Although NC cells are associated with a large number of human health conditions, including cleft lip and cleft palate, rare syndromes, and cancers [\(Watt and Trainor, 2013](#page-13-0); [Charney et al., 2021](#page-11-1)), comparatively little is understood regarding the formation of human NC (hNC) cells. Mowat-Wilson syndrome (MWS) is a neurocristopathy caused by heterozygous mutations in ZEB2 (ZFHX1B/SIP1) ([Cacheux et al., 2001](#page-11-2); [Waka](#page-12-0)[matsu et al., 2001;](#page-12-0) [Mowat et al., 1998\)](#page-12-1). MWS patients exhibit a characteristic facial gestalt—which includes a high forehead, broad nasal bridge, posteriorly rotated ears with uplifted earlobes, hypertelorism, and an open mouth ([Adam et al., 2006](#page-11-3); [Ivanovski et al., 2018](#page-11-4))—and intellectual disability, and they frequently present with microcephaly, congenital heart defects, and Hirschsprung's disease, among other anomalies ([Ivanovski et al., 2018\)](#page-11-4). This phenotype is consistent with the role of ZEB2 as a major developmental regulator of both the neural and NC lineages.

ZEB2 is a multi-zinc finger transcriptional repressor that recognizes and binds to consensus E-box binding motifs ([Verschueren et al., 1999\)](#page-12-2) and can interact with the receptor-activated SMADs of the BMP and TGF- β pathways to inhibit the expression of downstream targets [\(Postigo,](#page-12-3) [2003](#page-12-3); [Verschueren et al., 1999](#page-12-2)). It is known for its role as a regulator of the epithelial-to-mesenchymal transition

(EMT) in both embryonic development and cancer and functions extensively in the development of the central nervous system [\(Fardi et al., 2019](#page-11-5); [Vandewalle, 2005](#page-12-4)). However, its precise function in NC cell specification, formation, and differentiation, particularly during human development, is not well understood.

Recent advances in stem cell technologies have allowed for the investigation of hNC cell formation and differentiation in vitro [\(Lee et al., 2010](#page-11-6); [Menendez et al., 2011;](#page-12-5) [Leung](#page-11-7) [et al., 2016;](#page-11-7) [Gomez et al., 2019;](#page-11-8) [Hackland et al., 2019\)](#page-11-9). In this study, we examined the role of ZEB2 in early hNC development using a human embryonic stem cell (hESC) based model of cranial hNC induced through two days of exogenous Wnt signaling [\(Gomez et al., 2019](#page-11-8)). This model is consistent with the requirement for Wnt, BMP, and FGF signals during NC induction, and a detailed assessment of molecular markers reveals time points similar to developmental stages seen in vivo such as a neural plate border (NPB)-like and NC state characterized by expression of all known markers ([Leung et al., 2016](#page-11-7); [Gomez et al., 2019;](#page-11-8) [Pra](#page-12-6)[sad et al., 2020a\)](#page-12-6).

Using this model, we previously identified the early expression of ZEB2 and suggested it was among the earliest factors responsive to Wnt signaling during NC formation ([Leung et al., 2016\)](#page-11-7). Here, we reveal the gene network regulated by ZEB2 during hNC cell induction. We find that ZEB2 is rapidly activated and continuously expressed during hNC induction, and this expression is consistent with early Zeb2 expression in the chick embryo. Knockdown of ZEB2 results in significant changes in the expression of genes associated with the NC cell state and the EMT, as

Figure 1. Expression of ZEB2 in human neural crest and early chick embryos

(A) qRT-PCR analysis of ZEB2 expression during hNC cell induction. Data from 3 independent experiments with SEM. *p \leq 0.05, **p \leq 0.01, and ***p \leq 0.001.

well as the up-regulation of genes associated with the preplacodal and non-neural ectoderm. To gain insight into the repressive mechanisms of ZEB2, we examined ZEB2 N-terminal mutant hNC cells and their derivatives. Mutant ZEB2 lacking the nucleosome remodeling and deacetylase (NuRD) complex interacting domain loses the ability to interact with HDAC1, and chromatin accessibility analysis revealed derepressed putative enhancers during hNC induction. ZEB2 mutant hNC cells further displayed a reduced ability to terminally differentiate into osteoblasts, peripheral neurons, and neuroglia. Finally, we reveal that the gene expression changes resulting from this mutation can be rescued through the inhibition of BMP signaling, indicating that ZEB2 plays a role in modulating the proper levels of BMP signaling required for hNC formation. This work sheds light on the role of ZEB2 during hNC formation and provides a basis for further studies exploring the mechanisms underlying MWS.

RESULTS

ZEB2 is rapidly expressed during NC induction

Zeb2 transcripts are expressed in the neural epithelium and in the prospective and migrating NC cells in mouse, chick, and frog [\(van Grunsven et al., 2000](#page-11-10); [Putte et al., 2003;](#page-12-7) [Rogers et al., 2013](#page-12-8)). Using qRT-PCR, in our model of cranial hNC [\(Gomez et al., 2019](#page-11-8)) we identified ZEB2 expression at day 1 of hNC induction and a continued increase in expression over the course of 5 days [\(Figure 1A](#page-1-0)). RNA sequencing (RNA-seq) analysis confirms this expression pattern, and further reveals the onset of ZEB2 expression as early as 12 h (data not shown). These findings confirm and expand upon our previously reported hNC expression patterns [\(Leung et al., 2016](#page-11-7)) and indicate that ZEB2 is rapidly activated and maintained throughout hNC formation.

In the amniote chick embryo, Zeb2 has been observed in the prospective neural plate (Hamburger-Hamilton stage 4 [HH4] and HH5), the NPB (HH7), and in the migrating NC cells (HH9–HH13) ([Acloque et al., 2017;](#page-11-11) [Rogers et al.,](#page-12-8) [2013\)](#page-12-8). Similar to the rapid expression of ZEB2 in hNC cells, using in situ hybridization we observed Zeb2 expression throughout the entire epiblast of the chick HH3 gastrula embryo ([Figure 1](#page-1-0)B), prior to the expression of earliest NC specification marker Pax7 ([Basch et al., 2006](#page-11-12)). Consistent with previous reports, at HH4+, Zeb2 becomes restricted to the prospective neural plate and NC, and by HH8 Zeb2 expression is observed in the neural folds [\(Figure 1B](#page-1-0)). In the HH12 embryo, Zeb2 expressing cells are observed in the neural tube and in streams of migrating NC ([Figure 1](#page-1-0)B). Together, these findings indicate that expression of ZEB2 transcripts begins at very early stages of amniote NC specification and is maintained throughout stages of NC formation.

ZEB2 regulates the expression of NPB and NC genes during hNC induction

To address the role of ZEB2 during early hNC induction, we used a small interfering RNA (siRNA)-based knockdown of ZEB2 in our hNC model [\(Figure 2](#page-2-0)A). Knockdown assessed at day 2 of hNC induction revealed an \sim 80% reduction in ZEB2 protein expression ([Figure S1](#page-10-0)A) and a ${\sim}50\%$ reduction in ZEB2 transcripts ([Figure S1](#page-10-0)B). Using qRT-PCR, we observed an increase in NPB gene expression at day 3 and a decrease of NC-specifier gene expression at day 5 [\(Fig](#page-10-0)[ure S1C](#page-10-0)). Consistent with previous reports ([Putte et al.,](#page-12-7) [2003;](#page-12-7) [Rogers et al., 2013;](#page-12-8) [Vandewalle, 2005](#page-12-4)), CDH1 expression was increased.

(B) Volcano plots representing RNA-seq differentially expressed genes measured between non-targeting control and ZEB2 knockdown at day 3 and day 5. Blue, fold change ≥ 1.5 and adjusted p ≤ 0.05 ; red, fold change ≤ -1.5 and adjusted p ≤ 0.05 ; gray, -1.5 < fold change $<$ 1.5 and/or adjusted $p > 0.05$.

(C) Gene expression changes of select gene modules measured using RNA-seq following ZEB2 knockdown.

(D) Gene enrichment analysis of hNC day 5 differentially expressed genes.

To examine the global gene expression changes, we performed RNA-seq at hNC day 3 and day 5 following ZEB2 knockdown and compared it with the stage-matched non-targeting control (NTC) [\(Figure 2](#page-2-0)A). At day 3, 341 genes were significantly differentially expressed, with 218 genes up-regulated and 123 genes down-regulated [\(Fig](#page-2-0)[ure 2](#page-2-0)B, top; [Table S1](#page-10-0)). Pathway enrichment analysis revealed NC differentiation as the top enriched pathway in up-regulated genes, with terms associated with TGF- β signaling also enriched [\(Figure S1D](#page-10-0)). We observed the upregulation of NPB genes (e.g., PAX7, MSX1/2, DLX5), NC specifiers (e.g., FOXD3, SOX9, SNAI2, ID factors), and ligands and signaling modulators associated with the BMP and Wnt signaling pathways [\(Figures 2B](#page-2-0) and 2C). Of note, the NPB/NC-specifier gene ZIC1 was among the 123 down-regulated genes following ZEB2 knockdown at day 3.

At day 5, the knockdown of ZEB2 resulted in significant expression changes of 1,105 genes, with 802 genes up-regulated and 303 genes down-regulated [\(Figure 2](#page-2-0)B, bottom; [Table S1](#page-10-0)). Although NPB and NC-specifier genes were upregulated at day 3, NPB and NC-specifier genes were down-regulated at day 5 [\(Figures 2B](#page-2-0) and 2C) – indicating a failure of proper NC cell formation. Components of the Wnt signaling pathway including ligands WNT1, WNT3A, and WNT7B, along with the Wnt effector SP5, were also down-regulated at day 5. Consistent with this, pathway enrichment analysis revealed NC differentiation and Wnt signaling pathway at the top enriched terms among the day 5 down-regulated genes [\(Figure 2D](#page-2-0)). Genes up-regulated at day 5 were enriched for terms related to the regulation of the extracellular matrix [\(Figure 2D](#page-2-0)), and we observed changes in the expression of CDH1, CDH2, and CDH3, as well as claudins and Eph receptors [\(Figure 2C](#page-2-0)). Finally, at day 5, we observed the up-regulation of pre-placodal and non-neural ectoderm markers ([Figures 2](#page-2-0)B and 2C). The day 5 decrease of NC gene expression together with the increase in expression of pre-placodal and nonneural ectoderm markers suggests a requirement for ZEB2 in ectodermal cell fate patterning. Taken together, these findings suggest a role for ZEB2 in the proper formation of hNC cells where the misregulation of NPB factors and signaling molecules at day 3 results in impaired formation of NC cells at day 5.

The ZEB2 N terminus is required for hNC cell formation and differentiation

ZEB2 is a transcriptional repressor which recruits the NuRD complex through an N-terminal interaction domain (Verstappen et al., [2008](#page-12-9)) [\(Figure 3](#page-4-0)A). The NuRD complex promotes chromatin repression through the recruitment of HDAC1/2 and ATP-dependent nucleosome remodeling through CHD3/4 ([Ahringer, 2000\)](#page-11-13). Importantly, frameshift causing mutations in the ZEB2 N terminus have been reported in MWS patients [\(Ivanovski et al., 2018\)](#page-11-4). To gain insight into the requirement of the ZEB2 N terminus during hNC cell formation, we made use of CRISPR-Cas9 genome editing to generate an hESC line containing a homozygous N-terminal ZEB2 mutation (ZEB2 N-mutant) [\(Figure 3A](#page-4-0)). In this cell line, a frameshift causing mutation in exon 3 is predicted to result in the use of an alternative start codon in exon 4 with the resulting truncated ZEB2 protein lacking the first 112 amino acids [\(Figures 3](#page-4-0)A and [S2A](#page-10-0)). This ZEB2 N-mutant hESC line retains normal expression of pluripotency factors when cultured under non-differentiating conditions as assessed by immunofluorescence staining for POU5F1 and SOX2, and RNA-seq transcriptomic analysis [\(Figures S2B](#page-10-0) and S2C). Western blot analysis confirmed the expression of truncated ZEB2 N-mutant compared with wild-type (WT) ZEB2 in day 5 hNC cells, with the expression level of ZEB2 N-mutant equal to full-length ZEB2 in the isogenic WT cells [\(Figures 3B](#page-4-0) and [S2](#page-10-0)D). Furthermore, endogenous co-immunoprecipitation revealed the loss of HDAC1 interaction in the ZEB2 N-mutant compared with WT in day 5 hNC cells [\(Figure 3](#page-4-0)C). This finding suggests that the NuRD-interacting domain is required for ZEB2's association with HDAC1 during hNC cell formation.

We next used RNA-seq to assess the transcriptional changes during NC induction resulting from the loss of the N terminus [\(Figures 3D](#page-4-0) and [S3](#page-10-0)A; [Table S2](#page-10-0)). At day 3, we identified 552 differentially enriched genes in ZEB2 mutant NC compared with WT, including the up-regulation of genes encoding NPB markers, NC specifiers, and BMP ligands and regulators. Pathway enrichment analysis revealed the significant enrichment of terms associated with NC cell differentiation ([Figure S3B](#page-10-0)). At day 5, 865 genes exhibited significant expression changes, revealing the down-regulation of NC specifiers and Wnt signaling ligands, and the up-regulation of genes associated with extracellular matrix organization and the non-neural and pre-placodal ectoderm fates [\(Figure S3C](#page-10-0)). Finally, genes associated with NC terminal derivatives, including Schwann cell markers GAP43 and S100B, osteoblast marker BGLAP, and peripheral neuron markers POU4F1 and TAC1 were also differentially enriched ([Table S2\)](#page-10-0).

MWS patients exhibit craniofacial and neurological anomalies that appear associated with the NC lineage. Hence, we assessed the role of ZEB2 in the formation of NC derivatives including craniofacial bone and peripheral neurons and glia. Osteoblast differentiation was severely affected in ZEB2 N-mutant hNC cells compared with WT as observed through calcification after a 30-day differentiation [\(Figure 3](#page-4-0)E). We further identified an approximately 50% decrease in cell proliferation in the ZEB2 mutant osteoblasts using BrdU staining ([Figure S3](#page-10-0)D). Next, we assessed the effect of ZEB2 N-mutant on Schwann cell

Figure 3. N-terminal ZEB2 truncation inhibits neural crest cell formation and differentiation

differentiation. Through immunofluorescence and qRT-PCR, we observed a marked decrease in Schwann cell markers at the end of a 21-day differentiation of Schwann cells from ZEB2 N-mutant hNC cells [\(Figures 3](#page-4-0)F and 3H). We also observed the up-regulation of HEY2, a negative regulator of Schwann cell maturation and a putative target of ZEB2 ([Quintes et al., 2016](#page-12-10)) ([Figure 3H](#page-4-0)).

Finally, we examined peripheral neural differentiation in the ZEB2 N-mutant background at day 10 ([Figures 3G](#page-4-0) and 3I) and day 26 [\(Figures S3](#page-10-0)E and S3F). Peripheral neural markers were significantly misregulated at both time points. At day 10, markers including BRN3A, ISL1, NGN1, RUNX1, and NTRK1 were up-regulated and PRPH, SLC15A3, and SOX10 were down-regulated, with the continued up-regulation of BRN3A and NGN1 and down-regulation of PRPH, at day 26. Interestingly, at day 26, NTRK1 was down-regulated [\(Figure S3E](#page-10-0)). Immunofluorescence further validated the changes in PRPH and ISL1 protein expression as well as reduced proliferation and axonal projections in the ZEB2 mutant cells compared with WT ([Figure S3F](#page-10-0)). Together, these findings indicate that the ZEB2 N terminus is required for its proper function during hNC cell induction and suggest a misregulation in the NC gene regulatory network in MWS causing ZEB2 truncations.

ZEB2 N-mutant alters hNC chromatin accessibility

As mutant ZEB2 loses interaction with HDAC1 ([Figure 3](#page-4-0)C), we hypothesized that it is unable to facilitate repression of enhancers in the NC gene regulatory network. To explore changes in the epigenetic landscape, we performed an assay for transposase-accessible chromatin with sequencing (ATAC-seq) on WT and ZEB2 mutant day 3 and day 5 hNC. Correlation analysis of the ATAC-seq reads in each condition revealed that the data clusters on the basis of NC stage, not sample type ([Figure S4](#page-10-0)). We identified differentially enriched peaks at each stage, including 691 peaks that were shared between day 3 and day 5 [\(Fig](#page-6-0)[ure 4](#page-6-0)A; [Table S3\)](#page-10-0). Our finding that most differentially enriched peaks were derepressed supports the role of the NuRD complex and the canonical function of ZEB2 as a repressor.

We associated, within 500 kb, the differentially enriched regions at each day with 2,114 unique genes at day 3 and 8,206 unique genes at day 5 [\(Table S3](#page-10-0)), which include genes associated with NC, NC derivatives, non-neural ectoderm, and pre-placodal ectoderm. For example, at day 3, we observed increased regions of accessibility associated with BMP2 and BMP5 [\(Figure 4B](#page-6-0)), consistent with the day 3 upregulation of these transcripts. We also observed peaks at both day 3 and day 5 that were differentially enriched in a dynamic fashion, including peaks associated with PAX7 and the pre-placodal markers EYA1 and EYA2 [\(Figure 4](#page-6-0)B). Finally, we identified differentially enriched peaks associated with NC cell derivatives, including GAP43 (Schwann cells), MITF (melanocytes), COL2A1 (chondrocytes), ALPL (osteoblasts), and POU4F1 (peripheral neurons) [\(Figure S5\)](#page-10-0).

To explore the temporal dynamics of the differentially enriched peaks, we generated heatmaps representing the ATAC-seq signal over the day 3 and day 5 differentially enriched peaks, which were clustered using k-means [\(Fig](#page-6-0)[ure 4](#page-6-0)C; [Table S3\)](#page-10-0). At both time points, we identified clusters representing stage-specific derepression (e.g., day 3 clusters 1, 2, and 5 and day 5 clusters 3, 4, and 7) and repression (day 3 cluster 3 and day 5 clusters 5 and 8), as well as clusters containing prematurely derepressed peaks (day 3 clusters 1 and 4). This analysis suggests that ZEB2's regulation of chromatin accessibility is highly stage specific.

These observed temporal dynamics of enhancer accessibility suggest that perhaps ZEB2-regulated peaks are bound by different transcription factors at different times during NC formation. To examine the putative proteins that bind to the differentially enriched regions, we performed de novo motif analysis on the DNA sequences under the differentially enriched peaks ([Figure 4D](#page-6-0); [Table S4](#page-10-0)). Motif analysis was carried out on ZEB2 N-mutant increased peaks at day 3 and day 5 and day 5 ZEB2 N-mutant decreased peaks. At both time points, we identified the enrichment of ZEB2 and TFAP2 motifs underneath the ATAC-seq

increased peaks. At day 5, binding motifs for the nuclear hormone receptor superfamily and the SOX family were found within the increased accessibility peaks, while enriched motifs found under the ZEB2 N-mutant decreased accessibility peaks include those for homeobox containing transcription factors and RFX transcription factors. Our de novo motif analysis did not identify the ZEB2-binding motif as enriched under the peaks with decreased ATAC-seq accessibility, suggesting that the observed decrease in gene expression, including the down-regulation of NC

genes, in most cases is likely to be an indirect result of perturbations in the gene regulatory network.

ZEB2 N terminus is required to modulate levels of BMP signaling during hNC cell formation

Transcriptomic analysis of ZEB2 knockdown and ZEB2 N-mutant hNC both revealed the up-regulation of BMP ligands, regulators, and targets, particularly at the NPB-like state day 3 [\(Figure 5](#page-7-0)A). Studies in animal models suggest that attenuated levels of BMP signaling is required to

Figure 5. Inhibition of BMP signaling during neural crest induction rescues the ZEB2 truncation phenotype

properly induce NC at the NPB, which is subsequently followed by a reactivation of BMP signaling to promote the expression of NC specifiers [\(LaBonne and Bronner-Fraser,](#page-11-14) [1998;](#page-11-14) [Marchant et al., 1998;](#page-12-11) [Steventon et al., 2009](#page-12-12)). Interestingly, transcriptomic analysis over the time course of hNC induction revealed low expression of BMP ligands through day 3, increasing at day 5 ([Figure 5](#page-7-0)B). ZEB2 is a known Smad binding partner with the ability to inhibit BMP signaling ([Postigo, 2003](#page-12-3); [Verschueren et al., 1999\)](#page-12-2). Although the role of ZEB2 has been well documented to inhibit BMP signaling during neural development [\(Nitta](#page-12-13) [et al., 2004](#page-12-13)), its role in modulating BMP signaling during NC cell formation is unknown. To address this, we used the small molecule BMP inhibitor DMH1 to rescue the gene expression changes observed in ZEB2 N-mutant hNC [\(Figure 5](#page-7-0)C). Through careful titration, we found that concentrations of less than 100 nM were sufficient to rescue the gene expression changes observed in the ZEB2 N-mutant hNC at both day 3 and day 5 ([Figures 5](#page-7-0)D and 5E). Gene expression rescue was observed in a dose dependent manner. Although 12 nM DMH1 is significant to rescue the NPB/NC markers assayed, we noted that higher doses (50–100 nM) were needed to rescue the non-neural ectoderm markers DLX5 (day 3) and CDH1 (day 5). Together, these findings support the notion that the premature up-regulation of BMP signaling is a hallmark of ZEB2 loss of function and that the modulation of BMP signaling during early hNC is a critical function of ZEB2.

DISCUSSION

MWS is a rare disorder caused by heterozygous mutations in ZEB2 and marked by characteristic facial features, intellectual defects, and other anomalies. Our study interrogated the role of the ZEB2 repressor during hNC cell formation and suggests a role for ZEB2 in promoting the NC lineage and repressing the non-neural and pre-placodal ectoderm fates. Furthermore, our work using an N-terminal mutant of ZEB2 reveals the importance of the NuRD-interacting domain in ZEB2 regulation of NC cell development and suggests that ZEB2 functions in part to modulate the proper levels of BMP signaling during prospective NC stages.

We identified ZEB2 expression starting at 12 h post-induction of hNC from hESCs and significantly increasing at day 1 and day 2 prior to the expression of NPB genes at day 3. In agreement with this, we observed Zeb2 transcripts at stage HH3 of chick epiblast. Our findings indicate that Zeb2 is expressed broadly in the upper layer of the gastrulating chick embryo including the territory shown to correspond to specified NC [\(Basch et al., 2006](#page-11-12); [Prasad et al.,](#page-12-14) [2020b\)](#page-12-14) and precedes expression of Pax7 in the NPB. This is consistent with the early gastrula stage expression of zeb2 in Xenopus, with transcripts first detectable in NF at stage 10 of early gastrula [\(van Grunsven et al., 2000\)](#page-11-10). However, the regulatory network governing ZEB2 expression in the early chick gastrula and its later modulation and restriction to the prospective neural plate and NPB remain unknown and should be the focus of future studies.

We explored the function of ZEB2 in hNC cell induction through both siRNA-mediated knockdown of ZEB2 during hNC induction and the generation of a hESC line containing an N-terminal ZEB2 mutant which lacks the repressive NuRD-interacting domain. Consistent with the role of ZEB2 as a EMT regulator [\(Comijn et al., 2001;](#page-11-15) [Vandewalle,](#page-12-4) [2005](#page-12-4)) during development ([DaSilva-Arnold et al., 2018](#page-11-16); [Kerosuo and Bronner-Fraser, 2012;](#page-11-17) [Putte et al., 2003](#page-12-7); [2007](#page-12-15); [Rogers et al., 2013](#page-12-8); [van den Berghe et al., 2013\)](#page-12-16) and invasive cancer ([Rosivatz et al., 2002](#page-12-17); [Elloul et al., 2005](#page-11-18); [Im](#page-11-19)[amichi et al., 2007;](#page-11-19) [Xia et al., 2010](#page-13-1)), the loss of ZEB2 in hNC resulted in changes in the expression of genes associated with EMT, such as cadherins. In addition, ZEB2 has been implicated in lineage specification [\(Chng et al., 2010](#page-11-20); [Stry](#page-12-18)[jewska et al., 2016](#page-12-18)) and cell differentiation including corticogenesis ([Seuntjens et al., 2009\)](#page-12-19) and melanogenesis ([Denecker et al., 2014\)](#page-11-21), among others. We find that ZEB2 is required for the proper expression of NPB and NC-specifier genes, as well as WNT and BMP signaling pathway components. We further observed the up-regulation of pre-placodal and non-neural ectoderm genes at both day 3 and day 5 upon loss of ZEB2 expression. These findings suggest a model whereby ZEB2 is required early to promote

proper NC specification and inhibition of the pre-placodal and non-neural ectoderm fates. Consistent with this, a lack of boundary between the neural and non-neural ectoderm has been observed in ZEB2-null mice ([Putte et al., 2003\)](#page-12-7).

We observed a global increase in DNA accessibility in ZEB2 N-mutant hNC, including differentially enriched peaks within or nearby NPB, NC, and PPE genes. This suggests that the loss of functional ZEB2 relieves repression of nearby putative enhancers. Importantly, motif analysis on the DNA sequence under the differentially enriched peaks revealed the enrichment of the ZEB2-binding motif under the regions of increased accessibility, suggesting that many of these regions are likely to be directly bound and repressed by ZEB2 via the NuRD complex. The generation of ZEB2 occupancy maps during hNC induction will be important to confirm ZEB2 binding to putative enhancers. Our motif analysis also revealed the enrichment of additional motifs including the pioneer factor TFAP2, which functions during NPB and NC cell specification ([Rothstein and Simoes-Costa, 2019](#page-12-20)). This raises the intriguing possibility that TFAP2A pioneers ZEB2-modulated enhancers during hNC cell specification, and future analysis of TFAP2 occupancy of ZEB2-regulated regions will be necessary.

ZEB2 is known to modulate TGF- β signaling through interactions with receptor-activated Smads ([Nitta et al., 2004](#page-12-13); [Postigo, 2003](#page-12-3); [Verschueren et al., 1999](#page-12-2)), as well as regulate BMP4 through direct enhancer binding [\(van Grunsven](#page-11-22) [et al., 2007](#page-11-22)). Our finding that that suppression of BMP signaling using a small molecule inhibitor can rescue the ZEB2 mutant NC phenotype suggests that a major function of ZEB2 during early NC specification is to modulate the appropriate levels of BMP signaling. This finding, together with our transcriptomic and epigenetic analyses, leads us to speculate that ZEB2 regulates the expression of at least BMP2 and BMP5 during early hNC specification. Importantly, the misregulation of BMP signaling during the prospective NC stage would suggest a mechanism for our observation of increased PPE/NNE gene expression, as these factors respond to increased levels of BMP signaling ([Saint-Jeannet and Moody, 2014\)](#page-12-21). Although the SMAD binding motif was not identified as enriched in our de novo motif analysis, a targeted scan for the 5 bp GC motif ([Martin-Malpartida et al., 2017](#page-12-22)) revealed an approximately 70% co-occurrence between the ZEB2 and SMAD motifs at both day 3 and day 5. It remains to be seen how ZEB2 interacts with R-SMADs in the downstream regulation of BMP signaling. Importantly, the derepression of putative enhancers near NPB genes in ZEB2 mutant cells, coupled with the day 3 increase in gene expression, suggests that ZEB2 is involved in the direct repression of these genes. It will be crucial to investigate whether R-SMADs are also

involved in target gene regulation through these enhancers.

Most ZEB2 mutations in MWS patients identified to date are nonsense or frameshift mutations which are generally expected to result in the nonsense-mediated decay of transcripts or in non-functional protein products. As awareness of the syndrome has increased, however, genotypes including missense, in-frame deletions, and splice-site mutations have been identified [\(Ivanovski et al., 2018\)](#page-11-4), and the potential role of gain-of-function or dominant-negative mutations has been suggested [\(Heinritz et al., 2006\)](#page-11-23). Given the variable clinical manifestations of MWS, it is critical to assess the functional effects of ZEB2 mutations. Here, we examined the NC defects arising from the loss of the ZEB2 N terminus, which includes the NuRD-interacting domain. Mutations affecting the NuRD-interacting domain have been described in MWS patients [\(Ivanovski](#page-11-4) [et al., 2018](#page-11-4); [Zweier et al., 2006](#page-13-2)). Although these patients were reported to have a mild clinical phenotype, Zweier et al. noted the presence of the characteristic MWS facial features, suggesting that the N terminus might be important for the cranial NC cell lineage. Our analysis supports the requirement for the N terminus during hNC cell formation, as ZEB2 N-mutant NC cells displayed defects in osteoblast formation. This is in line with the NC-specific ablation of ZEB2 in mice, which demonstrated incomplete bone ossification ([Putte et al., 2007](#page-12-15)). Although bone ossification has not been thoroughly studied in MWS patients, delayed bone age has been reported in a subset of patients [\(Ivanovski et al., 2018](#page-11-4)). We note that our results might represent a stronger osteoblast phenotype because of the homozygous ZEB2 mutation in our hESC line, compared with the heterozygous mutations observed in MWS patients, and future interrogation of heterozygous ZEB2 mutant hNC cells will be important. Furthermore, craniofacial bone is also derived from the mesoderm. Although not a focus of this study, it is interesting to note that the mesoderm-specific loss of ZEB2 results in craniofacial and dental defects in mice [\(Teraishi et al., 2017](#page-12-23)). Detailed investigations into the role of ZEB2 in both NC and mesodermderived craniofacial bone is warranted.

MWS patients have been reported to experience an under-reaction to pain ([Evans et al., 2012](#page-11-24)), and ZEB2 has been shown to play a role in the formation of sensory dorsal root ganglia neurons in mice ([Pradier et al., 2013;](#page-12-24) [Ohayon et al., 2015](#page-12-25)). Our results indicate significant transcriptional changes in peripheral neurons derived from ZEB2 mutant hNC. ZEB2 has also been implicated in promoting Schwann cell differentiation, in particular by repressing inhibitors of differentiation ([Quintes et al., 2016;](#page-12-10) [Wu et al., 2016](#page-13-3)). Differentiation of our ZEB2 N-mutant NC cells into Schwann cells revealed a decrease in markers of Schwann cell precursors and myelination, and furthered revealed an increase in the expression of the Notch effector and Schwann cell differentiation inhibitor HEY2. The importance of ZEB2's NuRD-interacting domain has been reported in Schwann cell differentiation [\(Wu et al., 2016\)](#page-13-3). We also observed the misregulation of SOX2 expression in the Schwann cell lineage, which could be further attributed to the decreased expression of SOX2 in ZEB2 mutant NC cells.

Our findings suggest that ZEB2 plays an early role in hNC specification by modulating BMP signaling to repress preplacodal and non-neural ectodermal cell fates and promote the NC lineage. We find that truncated ZEB2 fails to repress putative enhancers during NC cell formation and leads to NC differentiation defects, providing a better understanding of the mechanisms underscoring the MWS phenotype.

EXPERIMENTAL PROCEDURES

Resource availability

Corresponding author

Requests should be directed to Rebekah Charney [\(rmcharney@](mailto:rmcharney@gmail.com) [gmail.com\)](mailto:rmcharney@gmail.com).

Materials availability

All unique reagents generated in this study are available with a completed Materials Transfer Agreement.

Data and code availability

All high-throughput sequencing data reported in this paper have been deposited in the database of Genotypes and Phenotypes (dbGaP: phs002701.v1.p1).

hESC culture

H1 hESCs (WA01; WiCell Institute) of passages 24–35 were maintained on plastic surfaces coated with Matrigel (Corning) in mTeSR1 (STEMCELL Technologies). Cultures were passaged every 4–5 days using Versene (Gibco) when approximately 80% confluency was reached. Cells were routinely tested for mycoplasma contamination using Lonza Bioscience's MycoAlert detection kit. The cell line was validated using STR analysis as per WiCell certificate of analysis.

NC cell induction and terminal differentiation

Cranial hNC induction was performed according to [Gomez et al.](#page-11-8) [\(2019\).](#page-11-8) Terminal differentiation of hNC cells was performed by treating day 5 hNC cells with Accutase and plating cells into respective differentiation media on Matrigel-coated surfaces. Additional details can be found in the [supplemental experimental](#page-10-0) [procedures.](#page-10-0)

siRNA knockdown of ZEB2

ZEB2 siRNA knockdown was performed according to [Prasad et al.,](#page-12-6) [2020a](#page-12-6) using SMART Pool siRNA (Dharmacon L-006914-02) and NTC siRNA (Thermo Fisher Scientific AM4611). Knockdown efficiency was assessed using qRT-PCR and western blot analysis at NC day 2.

Generation of H1 ZEB2 N-terminal mutant line

Guide RNA (gRNA) sequences targeting ZEB2 exon 3 were designed using Synthego CRISPR Design Tool and cloned into the AAVS-T2 gRNA backbone [\(Mali et al., 2013](#page-11-25)) upstream of the gRNA scaffold sequence. We used a dual gRNA approach with gRNA target regions separated by 190 bp. gRNA sequences were as follows: GGTGAACT ATGACAATGTAG and GAATCTCGTTGTTGTGCCAG. To generate the mutant hESC line, H1 hESCs of passage 23 were nucleofected with gRNA plasmids and plasmid expressing hCas9 ([Mali et al.,](#page-11-25) [2013](#page-11-25)) using a Lonza 4D-Nucleofector. Transfected cells were cultured as single cells in CloneR (STEMCELL Technologies) and resulting colonies were expanded and screened using PCR followed by gel electrophoresis to visualize putative positive clones with \sim 200 bp deletions. Genotypes of putative homozygous mutant clones were determined by TA cloning (pGEM-T Easy Vector System; Promega) followed by Sanger sequencing to resolve compound heterozygous clones from true homozygotes. The mutant line reported is homozygous for a 199 bp deletion.

Gene expression analysis

Total RNA was extracted at indicated time points during hNC cell formation and terminal differentiation using TRIzol reagent and purified using the Direct-zol RNA kit (Zymo Research). For qRT-PCR analysis, 0.5–1 µg RNA was reverse transcribed using the PrimeScript RT Reagent Kit (Takara). qPCR was performed using SYBR Premix Ex Taq II (Takara) with a primer concentration of 300 nM. Primer sequences are listed in [Table S5.](#page-10-0) Relative gene expression was calculated between the siRNA and NTC samples and normalized to the reference gene RPL13 using at least three biological replicates. For RNA-seq, RNA extracted from hNC cells was used with the NEBNext Poly(A) mRNA Magnetic Isolation Module (NEB) and the NEBNext Ultra II Directional RNA Library Prep Kit (NEB). RNA-seq experiments were performed in duplicate. Additional details can be found in the [supplemental experimental](#page-10-0) [procedures](#page-10-0).

Chromatin accessibility and de novo motif analysis

ATAC-seq was performed on day 3 and day 5 hNC cells induced from the H1 N-terminal ZEB2 mutant and the isogenic WT line using the ATAC-Seq Kit from Active Motif with an input of 100,000 cells per reaction. Library quality was assessed using Agilent Bioanalyzer and libraries were sequenced on a NovaSeq6000. Additional details can be found in the [supplemental experimental pro](#page-10-0)[cedures](#page-10-0). For de novo motif analysis, MEME was used with regions ±75 bp surrounding the peak center in differential enrichment mode. Peak sets representing up- and down-regulated peaks were analyzed independently with total peaks used as background. Putative binding proteins were identified using TOMTOM.

Chick in situ hybridization

Whole-mount chick in situ hybridization was performed as previously described ([Basch et al., 2006\)](#page-11-12). ZEB2 antisense RNA probe was generated using T7 reverse transcriptase from template amplified from total chicken cDNA. Images were acquired using a SPOT SE camera and software using a Nikon Eclipse 80i microscope. Expression at each stage was assessed in at least 3 embryos, and a representative image is shown.

Protein analysis

Co-immunoprecipitation of ZEB2 and HDAC1 was performed by lysing day 5 hNC at 4° C for 1 h with rotation in lysis buffer (10 mM Tris-HCl [pH 7.4], 137 mM NaCl, 0.5% NP-40, and 1 mM EDTA) supplemented with protease inhibitor and PMSF, followed by centrifugation. ZEB2 was immunoprecipitated using 1.5 mg ZEB2 antibody (Santa Cruz Biotechnology) with overnight incubation at 4° C, followed by incubation with Dynabeads Protein G (Invitrogen) for 4 h. Protein was eluted in Lammeli buffer with β-mercaptoethanol. Immunoprecipitated and input protein was separated using SDS-PAGE followed by western blot analysis for HDAC1. HDAC1 was detected using HRPconjugated secondary antibody, and the membrane subsequently stripped and probed for ZEB2. Western blotting to detect ZEB2 truncation was performed as previously described ([Prasad et al., 2020a\)](#page-12-6) using anti-ZEB2 and anti-GAPDH (Thermo Fisher Scientific).

Statistics

qRT-PCR graphs were generated and statistical analyses was performed using Prism. p values were determined using two-tailed unpaired t tests. RNA-seq and ATAC-seq were performed in duplicate, and 3 or more experiments were used for all others. RNA-seq differentially expressed genes were identified using DESeq2 (adjusted $p \le 0.05$ and fold change ≥ 1.5). Differentially enriched ATAC-seq peaks were determined using Homer (foldchange cutoff of 2 and replicate false discovery rate [FDR] cutoff of 0.05).
