Supporting Information

**ABSTRACT:** 2-((3-Cyano-4,6-dimethylpyridin-2-yl)oxy)-aceto-hydrazide **1** was used as the precursor for the synthesis of 5-thioxo-1,3,4-oxadiazol-2-yl)methoxy)nicotinonitrile **2**. The latter was alkylated with different alkylating agents to produce the S-alkylated products **3–6**. Galactosylation of 5-thioxo-1,3,4-oxadiazol-2-yl)methoxy)nicotinonitrile **2** produces a mixture of S- and N-galactosides **8** and **9**. The hydrazide **1** is converted to azide **10**, coupled with glycine methyl ester hydrochloride and a set of amines to produce the target coupled amides **11–15**. New compounds were assigned using NMR and elemental analysis. Compound **12** had potent cytotoxicity with  $IC_{50}$  values of 0.5 and 5.27  $\mu\text{M}$  against MCF-7 and HepG2 cell lines compared with doxorubicin, which displayed the following  $IC_{50}$ : 2.14 and 2.48  $\mu\text{M}$  for the mentioned cell lines, respectively. Regarding the molecular target, compound **12** exhibited potent PIM-1 inhibition activity with 97.5% with an  $IC_{50}$  value of 14.3 nM compared to Staurosporine (96.8%,  $IC_{50}$  = 16.7 nM). Moreover, compound **12** significantly activated apoptotic cell death in MCF-7 cells, increasing the cell population by total apoptosis by 33.43% (23.18% for early apoptosis and 10.25% for late apoptosis) compared to the untreated control group (0.64%), and arresting the cell cycle at S-phase by 36.02% compared to control 29.12%. Besides, compound **12** caused tumor inhibition by 42.1% in solid tumors in the SEC-bearing mice. Results disclosed that compound **12** significantly impeded cell migration and cell proliferation by interfering with PIM-1 enzymatic activity *via* considerable apoptosis-induction, which made it an attractive lead compound for the development of chemotherapeutics to treat breast cancer.

## INTRODUCTION

Due to its extensive and complex etiology, cancer poses a serious threat to human health.<sup>1</sup> Being the third most common cause of cancer death and the sixth most prevalent cancer type, liver cancer is a problem for the world's health. Furthermore, 14% of all cancer-related deaths among women are caused by breast cancer, which is the most prevalent cancer in the world.<sup>2,3</sup> Drug resistance continues to be one of the biggest obstacles in treating breast cancer, despite the recent identification of numerous potentially novel treatments that have shown significant therapeutic success.<sup>4</sup> In contrast, 75–85% of all instances of liver cancer are hepatocellular carcinoma (HCC). Despite the incidence of HCC, few drugs are available for clinical therapy, especially in the advanced stages; consequently, major efforts should be made.<sup>2,5</sup>

In addition to signaling pathways associated with malignancies, PIM kinases are crucial for many biological processes, such as cell differentiation, proliferation, and programmed cell death (apoptosis).<sup>6,7</sup> The original gene PIM-1, which serves as the proviral insertion site for the Moloney murine leukemia virus, is where the name PIM originates.<sup>8,9</sup> High levels of PIM

expression have been related in several studies to human epithelial and hematologic cancers, making them promising therapeutic targets.<sup>10,11</sup> Because PIM-1 kinase has a distinctive active site, it is simpler to develop small compounds that function as PIM-1 inhibitors.<sup>12,13</sup> PIM-1 elevations have been linked to the development and progression of cancer.<sup>14,15</sup> PIM-1 kinase was highly expressed in several tumor types, including breast, prostate, hepatic, colon, and pancreatic malignancies.<sup>16–18</sup> Consequently, it is a promising strategy to stop the spread of cancer by inhibiting PIM-1 using small-molecule drugs.<sup>19</sup>

Since many pharmaceutically and physiologically active substances, including etoricoxib, nifedipine, amlodipine, and clevidipine,<sup>20,21</sup> include the pyridine motif, some anticancer

**Figure 1.** Structures of selected FDA-approved drugs and bioactive lead compounds containing a pyridine moiety.

medications, including Veliparib, Niraparib, Olaparib, and Rucaparib, were revealed to have essential pharmacophoric groups due to the presence of an amide group, which functions as a hydrogen bond donor for the interaction with biological targets.<sup>22,23</sup> Compound 6-phenyl-*N*-(pyridin-3-yl)picolinamide (LGB321), the most powerful PIM inhibitor identified to date, has pyridine, amine, and amide groups in its structure that are required for hydrogen bond interactions with the residues of PIM-1's ATP-binding site.<sup>24,25</sup> While 2-(3-cyano-4,6-diphenylpyridin-2-yloxy)acetohydrazide **I** was said to have a potent effect that significantly inhibited HepG2 cell reproduction and

cell migration by interfering with PIM-1 enzymatic activity<sup>26</sup> (Figure 1). Moreover, by inhibiting PIM-1 enzymatic activity, 6-(4-(benzyloxy)phenyl)-4-(4-(dimethylamino)phenyl)-2-ethoxynicotinonitrile **II** demonstrated a strong action that drastically decreased PC3 cell reproduction and migration.<sup>27</sup> Compound **III** showed roughly equal activity against the HepG2 cell line as the reference drug in 2023 (IC<sub>50</sub> of 0.0486 M).<sup>28</sup> Compound **IV** showed the best antiproliferative activities with an IC<sub>50</sub> value of 1.18 μM against MCF-7, better than lapatinib as a reference standard (IC<sub>50</sub> = 4.69 μM).<sup>29</sup> Compounds **V** and **VI** were found to be the most active

Scheme 1. Alkylation of 5-Thioxo-1,3,4-oxadiazol-2-yl(methoxy)nicotinonitrile 2

Scheme 2. Galactosylation of 2 Produced S- and N-Galactosides

congeners against MCF-7 cells ( $\text{IC}_{50} = 0.22$  and  $1.88 \mu\text{M}$  after 48 h treatment;  $0.11$  and  $0.80 \mu\text{M}$  after 72 h treatment, respectively), with increased activity compared to the reference drug doxorubicin ( $\text{IC}_{50} = 1.93 \mu\text{M}$ ).<sup>30</sup>

Hybridization of the 1,3,4-oxadiazole moiety with other heterocyclic pharmacophores is a promising approach to overcome various disadvantages of current anticancer drugs, such as drug resistance, toxicity, and other side effects. Thus, the hybridization of 1,3,4-oxadiazole with pyridine may also lead to the development of new anticancer drugs with multiple action mechanisms. Zhang et al.<sup>31</sup> reported that the anticancer

activity of 1,3,4-oxadiazole-pyridine hybrid VII against four cancer cell lines (HepG2, MCF-7, SW1116, and BGC823) exhibited more potent activity ( $\text{IC}_{50} = 0.76$ – $12.21 \mu\text{M}$ ) than the positive control (5-Fluorouracil,  $\text{IC}_{50} = 5.26$ – $9.79 \mu\text{M}$ ).

As part of our continuous efforts to synthesize and discover novel anticancer drugs, we created stepwise biological work packages that involve cytotoxic screening and apoptosis induction.<sup>32–38</sup> In this work, novel pyridine compounds are designed and synthesized, and their antibreast and antiliver cancer properties are assessed.

Scheme 3. Azide Coupling of 10 with Glycine Methyl Ester Hydrochloride and Amines

## RESULTS AND DISCUSSION

The synthetic strategy was as follows: 2-((3-cyano-4,6-dimethylpyridin-2-yl)oxy)acetohydrazide **1** reacted with carbon disulfide and potassium hydroxide in ethanol under reflux conditions to afford 4,6-dimethyl-2-((5-thioxo-4,5-dihydro-1,3,4-oxadiazol-2-yl)methoxy)nicotinonitrile **2**. The 1,3,4-oxadiazole-thione moiety in **2** alkylated with a set of alkylating agents, including ethyl chloroacetate, benzyl chloride, allyl bromide, and amyl bromide, in the presence of potassium carbonate in acetone gave the S-alkylated products **3-4-6** respectively (Scheme 1).

The <sup>1</sup>H NMR of **2** showed the two methyl group proton signals at 2.42 and 2.44 ppm, the OCH<sub>2</sub> signal appeared at 5.55 ppm, the aromatic CH proton was found at 7.09 ppm, whereas the oxadiazole NH proton was detected at 14.69 ppm. The <sup>13</sup>C NMR displayed the two methyl group carbons at 20.11 ppm and 24.51 ppm, the OCH<sub>2</sub> carbon appeared at 58.05 ppm, while the thiocarbonyl carbon (C=S) was found at 178.38 ppm, which confirmed the thione form. S-alkylation was established based on the <sup>13</sup>C NMR signal of the methylene carbon attached to sulfur since the S-CH<sub>2</sub> signal values in ppm were 34.25 (**3**), 36.34 (**4**), 35.13 (**5**), and 32.44 (**6**).

Compound 5-thioxo-1,3,4-oxadiazol-2-yl)methoxy)-nicotinonitrile **2** was galactosylated with acetobromogalactose **7** under the same conditions to afford a mixture of S-galactoside **8** and N-galactoside **9**, which were separated using silica-column chromatography (Scheme 2).

In addition, 2-((3-cyano-4,6-dimethylpyridin-2-yl)oxy)acetohydrazide **1** is converted to azide **10** by the reaction with sodium nitrite and HCl under low temperature (-5 °C).

The azide **10** is coupled with glycine methyl ester hydrochloride via the azide coupling method in the presence of Et<sub>3</sub>N to give the glycinated compound **11**. Moreover, the azide **10** is coupled with a set of amines, including morpholine, piperidine, benzylamine, and allylamine, in the presence of Et<sub>3</sub>N to yield the amine-coupled products **12-15**, respectively (Scheme 3). The azide compound **10** missed any NH signal and showed the carbonyl carbon (C=O) signal at 176.17 ppm. The glycinated compound **11** showed the protons of the methoxy group proton at 3.64 ppm, the two-methylene groups detected at 3.88 and 4.92 ppm, and the NH appeared at 8.22 ppm. The carbonyl carbons were found at 168.38 and 170.51 ppm. The coupled amines showed new characteristic signals. Compounds **14** and **15** displayed NH at 8.45 and 8.21 ppm, respectively. The coupled amines **12-15** displayed the carbonyl carbons of the amide group at 165.97 ppm (**12**), 165.23 ppm (**13**), 167.83 ppm (**14**), and 167.42 ppm (**15**).

**Biology. Cytotoxicity Using the MTT Assay.** The synthesized compounds were tested for their cytotoxicity against breast MCF-7 and liver HepG2 cancer cells. Compounds demonstrated good cytotoxicity with a promising percentage of cell death at the maximum concentration [100 μM], as shown in Table 1. Compounds **11** and **12** revealed interesting IC<sub>50</sub> values against MCF-7 (0.73 and 0.5 μM, respectively), whereas compounds **6** and **12** showed the following IC<sub>50</sub> against HepG2 cell lines (5.27 and 6.6 μM, respectively), as shown in Table 2. The percentages of cell growth inhibition of MCF-7 and HepG2 cancer cells and MCF-10A normal cells against the concentration of tested compounds are summarized in Figure 2.

**Table 1. Percentage of Cell Growth Inhibition of the Tested Compounds against MCF-7 and HepG2 Lines Using the MTT Assay**

code	% of cell inhibition $\pm$ SD at [100 $\mu$ M]	
	MCF7	HepG2
2	41.92 $\pm$ 1.9	43.49 $\pm$ 1.8

14	48.76 $\pm$ 1.2	35.55 $\pm$ 1.1
doxorubicin	90.20 $\pm$ 2.1	79.13 $\pm$ 2.3

**Table 2. Cytotoxic IC<sub>50</sub> Values of the Promising Compounds against MCF7 and HepG2 Cell Lines Using the MTT Assay**

code	IC <sub>50</sub> $\pm$ SD [ $\mu$ M] <sup>a</sup>		
	MCF7	HepG2	MCF-10A
6	NT	6.64 $\pm$ 0.28	NT
11	0.73 $\pm$ 0.04	NT	NT
12	0.51 $\pm$ 0.02	5.27 $\pm$ 0.2	52.85 $\pm$ 2.1
doxorubicin	2.14 $\pm$ 0.1	2.48 $\pm$ 0.1	15.75 $\pm$ 0.63

<sup>a</sup>Values are expressed as the mean  $\pm$  SD of three independent triplets ( $n = 3$ ). Doxorubicin is a reference drug. NT: non-Tested. IC<sub>50</sub> values were calculated using the dose–response curve using EXCEL.

**PIM-1 Kinase Inhibitory Assay.** To highlight their effective molecular target, compounds **6**, **11**–**13**, with the highest cytotoxic activity against MCF-7 cells, were evaluated against PIM-1 inhibitory activities. As shown in Table 3, the investigated compounds displayed promising PIM-1 inhibitory capabilities with IC<sub>50</sub> values of 19.4, 42.3, 14.3, and 19.8 nM (percentage of enzyme inhibition by 90.1–97.5%) when compared to Staurosporine (IC<sub>50</sub> = 16.7 nM, 96.8%). As a result, compound **12** was studied further for apoptotic cell death in MCF-7 cells (Table 3).

**Apoptotic Investigation. Annexin V/PI Staining with Cell Cycle Analysis.** To investigate the apoptotic activity of compound **12** (IC<sub>50</sub> = 1.62  $\mu$ M, 48 h), flow cytometric evaluation of Annexin V/PI staining was utilized to examine apoptotic cell death in untreated and treated MCF-7 cells. Figure 3 shows that compound **12** dramatically increased apoptotic cell death in MCF-7 cells, increasing total apoptosis by 33.43% (23.18% for early apoptosis and 10.25% for late apoptosis) compared to the untreated control group (0.64%). As a result, **12**-treatment increased apoptosis by 52.2 fold.

Following that, DNA flow cytometry was utilized to determine the cell population in each cell phase after treatment with a cytotoxic agent. As shown in Figure 4, compound **12** administration raised the S-phase cell population by 36.02% compared to the control by 29.12%, while cells in other phases declined or increased insignificantly. As a result, chemical **12** caused apoptosis in MCF-7 cells, halting cell proliferation at the S-phase.

**Autophagy Assessment of 12-Treatment.** The investigated chemical **12** caused considerable autophagic cell death, activating autophagic cell death by  $87.6 \times 10^3$  cells compared

to  $32.8 \times 10^3$  for the control, demonstrating compound **12**'s autophagy activity and apoptosis-induction as a dual activity (Figure 5).

**Effect of 12 Treatment against Cell Migration Using Wound-Healing Activity.** As shown in Table 4 and Figure 6, the wounded area between cell layers following a scratch was partially filled by migrating MCF-7 control cells (95.6% wound closure), while only 71.8% of the wound was closed after 48 h of **12**-treatment.

**In Vivo (SEC-Bearing Mice).** A solid Ehrlich carcinoma cell was implanted, and compound **12** was injected intraperitoneally (IP) throughout the experiment to confirm its anticancer efficacy. Table 5 summarizes the outcomes of the tumor measurement experiments.

As a result, tumor proliferation revealed an increase in solid tumor mass of approximately 198.5 mg related to tumor potential. Following treatment with **12** and doxorubicin, the solid tumor mass decreased to 72.8 mg and 63.4 mg, respectively. As a result, treatments with **12** considerably reduced tumor volume from 274.8 mm<sup>3</sup> in the untreated control to 159.2 mm<sup>3</sup> and greatly decreased tumor proliferation by 42.1%. It reduced tumor volume to 112.3 mm<sup>3</sup> and suppressed tumor development by 59.1% compared to doxorubicin.

**Molecular Docking.** The molecular docking study validated the binding affinity of the promising active compound **12** toward the PIM-1 active site. Docking results highlighted its binding mode with a binding energy of  $-17.38$  Kcal/mol, and it formed a good binding interaction with Lys67 as an H-bond acceptor through the nitrile group. Besides the H-bond interactions, compound **12** made lipophilic interactions with the nonpolar amino acids, including Phe49, Ile104, Ile185, Leu174, Leu120, Ala65, and Val52. As seen in Figure 7, with the superimposition of compound **12** with the cocrystallized ligand, it exhibited the same binding mode with binding interactions.

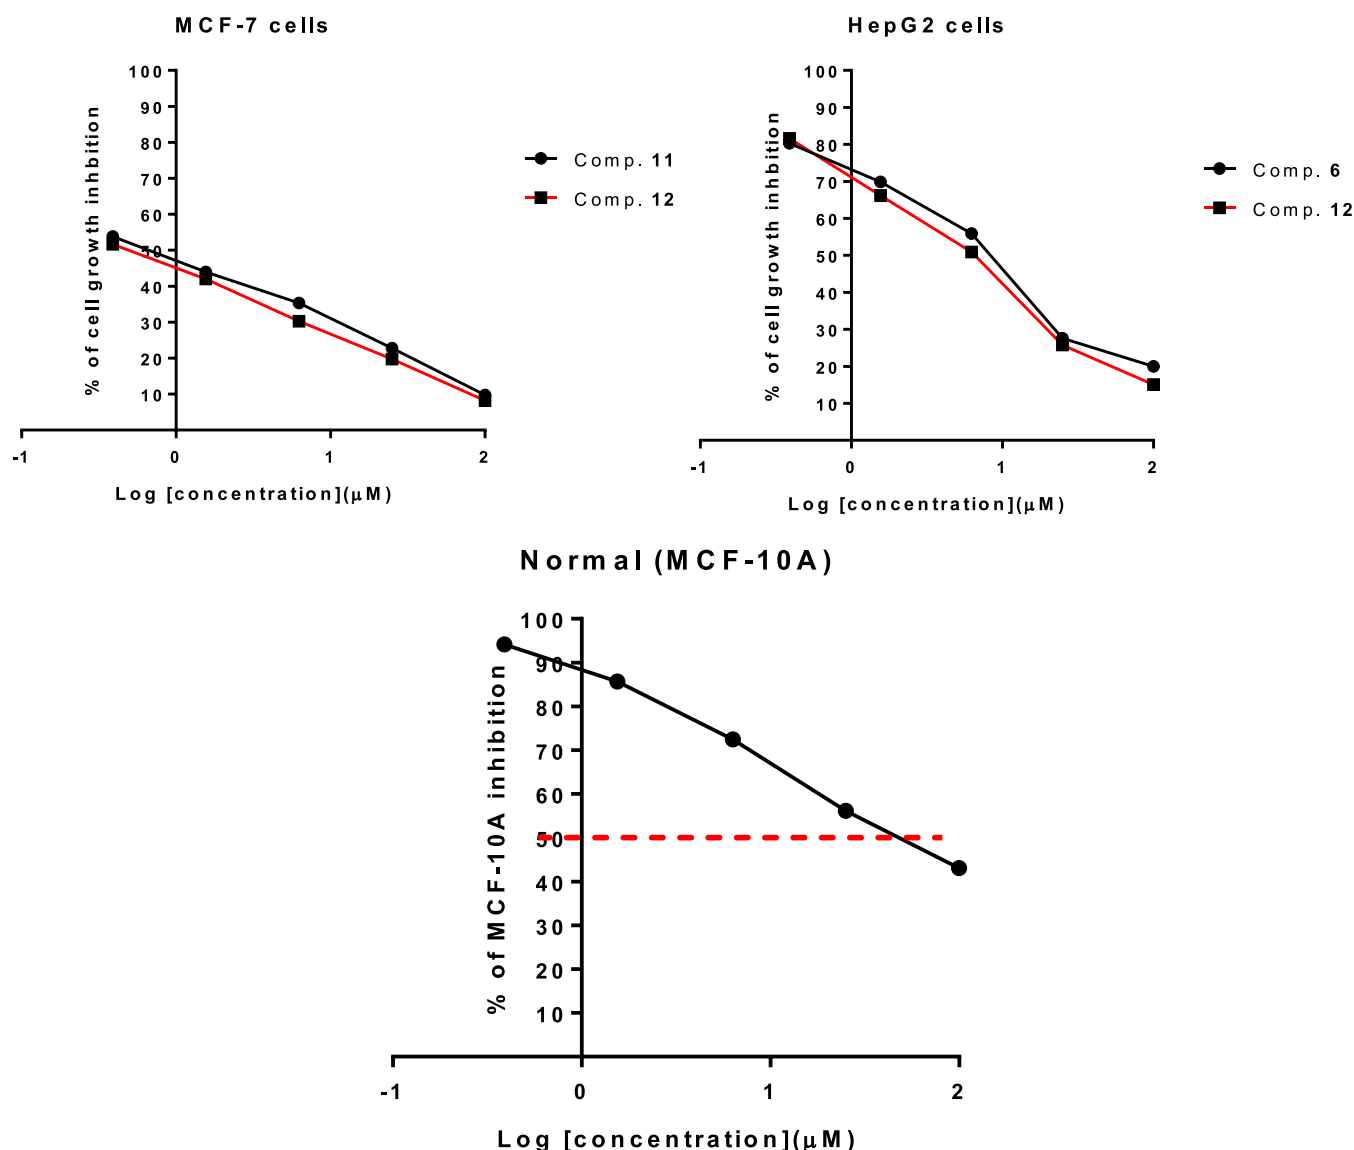

## EXPERIMENTAL PART

**Chemistry. General Procedures.** The values for the melting points are uncorrected and were determined in open capillaries using Temp-melt II melting point equipment. On silica gel 60 (230–400 mesh ASTM), flash chromatography was carried out. On silica gel 60 F254 aluminum plates (E. Merck, layer thickness 0.2 mm), thin layer chromatography was performed. The spots were found using a UV lamp. Using DMSO-*d*<sub>6</sub> and CDCl<sub>3</sub> as solvents, the <sup>1</sup>H and <sup>13</sup>C NMR spectra were captured on Bruker instruments at 400 MHz for <sup>1</sup>H NMR and 101 MHz for <sup>13</sup>C NMR, respectively. Using KBr and a Perkin Elmer 1430 ratio recording infrared spectrophotometer, Bruker's Fourier transform infrared spectrophotometry was used to record the IR spectra, and Flash EA-1112 equipment was used to do the CHNS-microanalysis.

**Synthesis of 2-((3-Cyano-4,6-dimethylpyridin-2-yl)oxy)acetohydrazide (1).** Procedures as mentioned in Keshk<sup>39</sup> Yield: 70%, mp 196 °C (Lit.<sup>39</sup> 198 °C); <sup>1</sup>H NMR (DMSO-*d*<sub>6</sub>, 400 MHz):  $\delta$  2.39 (s, 3H, CH<sub>3</sub>), 2.43 (s, 3H, CH<sub>3</sub>), 4.25 (s, 2H, NH<sub>2</sub>), 4.84 (s, 2H, OCH<sub>2</sub>), 6.99 (s, 1H, Hpy), 9.20 (s, 1H, NH); IR (KBr/cm<sup>-1</sup>): 3322, 3266 (NH, NH<sub>2</sub>), 2963 (C–H aliphatic), 2222 (CN), 1688 (C=O amide), 1605 (C=C); Elemental analysis Calcd for [C<sub>10</sub>H<sub>12</sub>N<sub>4</sub>O<sub>2</sub>]: C, 54.54; H, 5.49; N, 25.44 Found C, 54.44; H, 5.55; N, 25.3.

**General Procedure for Azide-Coupling of Amino Acid Methyl Ester and Amines.** A cold solution (0 °C) of sodium nitrite (0.14 g, 2.0 mmol) in water (6 mL) was added to a cold solution (–5 °C) of hydrazide **1** (1.6 mmol) in acetic acid (12 mL), hydrochloric acid (5 M, 6 mL), and water (50 mL). Following 30 min of stirring at the same temperature, the

**Figure 7.** Binding disposition as surface presentation (A) and ligand–receptor interaction (B) of the docked compound **12** toward the PIM-1 kinase active site. 3D images were generated using Chimera-UCSF software.

formed azide was removed using cold ethyl acetate and rinsed with a cold solution of  $\text{NaHCO}_3$  (5%) and water. In the following stage, azide **10** was employed without further purification after drying over anhydrous sodium sulfate.

For 20 min at 0 °C, glycine methyl ester hydrochloride or the corresponding amine (1.8 mmol) was agitated in 50 mL of ethyl acetate that also included 0.2 mL of triethyl amine. The produced triethyl amine hydrochloride was filtered out, and the filtrate was then added to the cold solution of azide **10** that had already been made. The mixture was then kept at ambient temperature for an additional 12 h after spending the first 12 h in the refrigerator. The reaction mixture was rinsed with a water and  $\text{NaHCO}_3$  (5%) solution before being dried on anhydrous sodium sulfate. The solvent was evaporated under a vacuum, and the leftover mixture of ethyl acetate and petroleum ether was recrystallized to produce the desired product.

## MATERIAL AND METHODS

**Biology. Cytotoxicity.** The breast cancer (MCF-7) and liver (HepG2) cells, which were obtained and grown in RPMI-1640 medium L-glutamine (Lonza Verviers SPRL, Belgium, cat#12-604F), were provided by the National Research Institute in Egypt. Both cell lines received 10% fetal bovine serum (FBS; Sigma-Aldrich, MO, USA) and 1% penicillin–streptomycin (Lonza, Belgium). On the second day, cells were exposed to the chemicals in concentrations of (0.01, 0.1, 1, 10, and 100 M). Cell viability was assessed using the MTT solution (Promega, USA) after 48 h.<sup>40</sup> The plate was incubated for 3 h after each well had been injected with 20 μL of MTT dye. The viability was calculated with respect to the control, and GraphPad Prism 7 was used to determine the IC<sub>50</sub> values.

**PIM-1 Kinase Inhibitory Assay.** The PIM-1 kinase test was done using an ELISA kit in accordance with manufacturer instructions (Kit #7573). To assess the inhibitory potency of drugs **6**, **11**, **12**, and **13** against the PIM-1 kinase activity, kinase inhibitory tests were carried out. The following calculation was used to compute the proportion in which chemicals inhibited autophosphorylation: 100-[(A treated)/(A control)-control] Using the GraphPad prism7 program, the IC<sub>50</sub> was calculated using the curves of the percentage inhibition of five concentrations of each chemical.<sup>41,42</sup>

**Investigation of Apoptosis. Annexin V/PI Staining and Cell Cycle Analysis.** 3–10<sup>5</sup> MCF-7 cells were added to 6-well culture plates, which were then placed in the incubator for the night. Following that, cells were treated for 48 h to compound **12** at its IC<sub>50</sub> levels. Following that, PBS was rinsed with ice-cold water before cells and media supernatants were gathered. The cells were then treated with "Annexin V-FITC solution (1:100) and propidium iodide (PI)" at a concentration of 10 g/mL for 30 min in the dark after being suspended in 100 L of annexin binding buffer solution, which is composed of 25 mM CaCl<sub>2</sub>, 1.4 M NaCl, and 0.1 M HEPES/NaOH, pH 7.4. Then, labeled cells were collected using the Cytotflex FACS system. The data were assessed using the cytExpert program.<sup>43</sup>

**Autophagy Evaluation Using Acridine Orange Quantitative Assessment.** Autophagic cell death is measured by flow cytometric analysis and an acridine orange lysosomal stain. After being exposed to the test substance for 48 h, MCF-7 cells (10<sup>5</sup> cells) were extracted by trypsinization and washed twice with ice-cold PBS (pH 7.4). The cells were stained with acridine orange (10 mM) and incubated at 37 °C in the dark for 30 min. After staining, cells were injected into the ACEA NovoCyt flow cytometer (ACEA Biosciences Inc., San Diego, CA, USA), and a FL1 signal detector (lex/em 488/530 nm) was used to assess the fluorescent signals from acridine orange. After 12,000 events were recorded for each sample, ACEA NovoExpress software (ACEA Biosciences Inc., San Diego, CA, USA) was used to calculate the net fluorescence intensities (NFI) for each sample.

**Wound-Healing Assay (Scratch Assay).** Research from the past has referenced the wound-healing test.<sup>44</sup> MCF-7 cells (4 × 10<sup>5</sup>/well) were added to 6-well plates containing starvation medium and then incubated at 37 °C for an overnight period. When it was determined that the cells had adhered to the well and that cell confluence had reached 90% the next day, a scratch of the cell monolayer was created using a sterile 1 mL pipet tip. To remove the cells from the plates, the cells were cleansed with starvation media. The medium was replaced with PBS right away after 48 h, the wound gap was inspected, and cells (both control and treated) were photographed using a digital camera mounted to an Olympus microscope. Measurements were made for the wound closure area.

**In Vivo.** The Suez Canal University Research Ethics Committee validated the experimental procedure (Approval number REC220/2023, Faculty of Science, Suez Canal University). Detailed methodology is provided in the supplementary file.

**Molecular Docking.** Maestro was used to construct, optimize, and energetically favor ligand structures. The X-ray crystallographic structure of PIM-1 kinase (PDB ID: 2OBJ)<sup>45</sup> was subjected to a molecular docking investigation using the AutoDock Vina software, followed by the Chimera-UCSF software after routine work.

## CONCLUSIONS

Compound **2** as 5-thioxo-1,3,4-oxadiazol-2-yl)methoxy)-nicotinonitrile was synthesized and coupled with alkyl halides to produce new compounds. The azide-coupling method used for coupling the azide **10** with glycine methyl ester and a set of amines. Compound **12** had potent cytotoxicity with IC<sub>50</sub> values of 0.5 and 5.27 μM against MCF-7 and HepG2, respectively. For molecular target, compound **12** exhibited potent PIM-1 inhibition activity with a 97.5% IC<sub>50</sub> value of 14.3 nM compared to Staurosporine (96.8%, IC<sub>50</sub> = 16.7 nM).

Compound **12** significantly activated apoptotic cell death in MCF-7 cells, increasing the cell population by total apoptosis by 33.43% (23.18% for early apoptosis and 10.25% for late apoptosis) compared to the untreated control group (0.64%), and arresting the cell cycle at S-phase by 36.02% compared to control 29.12%. Accordingly, compound **12** induced potent cytotoxicity against MCF-7 cells through PIM-1 inhibition with apoptosis-induction, and it can be developed as a chemotherapeutic antibreast cancer agent.
