Abstract

Objective: To examine the effect of digital health interventions (DHIs) compared to treatment as usual (TAU) on preventing and treating postpartum depression (PPD) and postpartum anxiety (PPA).

Data Sources: Searches in Ovid Medline, Embase, SCOPUS, Cochrane Database, and [ClinicalTrials.gov](#) for randomized controlled trials comparing DHIs to TAU for preventing or treating PPD and PPA. The primary outcome was the score on the first ascertainment of PPD or PPA symptoms after the intervention. Secondary outcomes included screening positive for PPD

or PPA—as defined in the primary study—and loss to follow-up, defined as the proportion of participants who completed the final study assessment compared to the number who were initially randomized.

Methods of Study Selection: Two authors independently screened all abstracts for eligibility and independently reviewed all potentially eligible full-text articles for inclusion. A third author screened abstracts and full-text articles as needed to determine eligibility in cases of discrepancy. For continuous outcomes, the Hedges method was used to obtain standardized mean differences (SMD) when the studies used different psychometric scales, and weighted mean differences (WMD) were calculated when studies used the same psychometric scales. For categorical outcomes, pooled relative risks (RR) were estimated.

Tabulation, Integration, and Results: Of 921 studies originally identified, 31 randomized controlled trials—corresponding to 5,532 participants randomized to DHI and 5,492 participants randomized to TAU—were included. Compared to TAU, DHIs significantly reduced mean scores ascertaining PPD symptoms (29 studies: SMD -0.64 (95% Confidence Interval (CI): -0.88 , -0.40), $I^2=94.4\%$) and PPA symptoms (17 studies: SMD -0.49 (95% CI: -0.72 , -0.25)), $I^2=84.6\%$). In the few studies that assessed screen-positive rates for PPD (n=4) or PPA (n=1), there was no significant differences between those randomized to DHI versus TAU. Overall, those randomized to DHI had 38% increased risk of not completing the final study assessment compared to those randomized to TAU (pooled RR 1.38 (95% CI 1.18 , 1.62), but those randomized to app-based DHI had similar loss-to-follow-up rates as those randomized to TAU (RR 1.04 (95% Confidence Interval: 0.91 , 1.19)).

Conclusion: DHIs modestly, but significantly, reduced scores assessing PPD and PPA symptoms. More research is needed to identify DHIs that effectively prevent or treat PPD and PPA but encourage ongoing engagement throughout the study period.

Tweetable statement:

In a meta-analysis of RCTs, digital interventions modestly but significantly reduced symptoms of postpartum depression and anxiety but had higher risk of loss-to-follow up compared to routine care.

Keywords

digital health intervention; postpartum depression; postpartum anxiety; perinatal mental health; smartphone application; internet; text message

Introduction

In the year after childbirth, approximately 15% of women experience postpartum depression (PPD)¹ and 20% experience postpartum anxiety (PPA).² Prior studies have demonstrated that interventions utilizing psychoeducation³ or psychotherapy (cognitive behavioral therapy (CBT),⁴ interpersonal therapy (IPT),⁵ or mindfulness⁶) effectively prevent and treat PPD and PPA. Unfortunately, less than 20% of women with PPD or PPA have access to these interventions.⁷ The inadequate dissemination of programs shown to improve

perinatal mental health has been attributed to the limited number of skilled mental health professionals who can provide psychoeducation or psychotherapy in the perinatal period.⁸

Digital health interventions (DHIs) may help expand access to evidence-based psychoeducation or psychotherapy-based perinatal mental health programs. Though the World Health Organization defines DHIs broadly as “a discrete functionality of digital technology that is applied to achieve health objectives,”⁹ DHIs may be defined pragmatically as interventions delivered directly to a patient via the internet, a smartphone application (app), or a text message or short-message system (SMS) program. DHIs have notable advantages when compared to in-person interventions. First, they are accessible to nearly all who reside in the United States: smartphone ownership rates are nearly universal among reproductive-aged patients (95% of individuals aged 18–49 years own a smartphone),¹⁰ and most households (77%)—even low-income (57%)¹¹ or rural households (72%)¹²—have broadband internet at home.^{11, 12} Second, DHIs bypass barriers such as lack of childcare or unreliable transportation that have been associated with reduced adherence to in-person postpartum care.^{13, 14} Lastly, DHIs are inherently scalable: once proven effective, DHIs can be widely disseminated without reducing intervention fidelity.

Prior meta-analyses have suggested that DHIs effectively improve PPD or PPA when compared to treatment as usual in randomized controlled trials.^{15–18} However, these meta-analyses have limitations: most only included internet-based DHIs,^{16–18} and the only meta-analysis that included multiple DHI modalities focused exclusively on the effect of DHIs on PPD¹⁵ despite the significant burden of PPA on perinatal populations. In addition, nine randomized controlled trials comparing DHIs to treatment as usual (TAU) have been published since 2021.^{19–27} Thus, an updated meta-analysis is warranted. The primary aim of this study is to assess the effect of DHIs compared to TAU on preventing or treating PPD and PPA. Secondary aims included assessing the effect of DHIs compared to TAU on treating PPD and PPA overall and the effect of specific DHI modalities on PPD and PPA prevention or treatment.

Methods

Sources

All written methodologies, including search strategies, used in this systematic review and meta-analysis were created according to standards and guidelines for conducting and reporting systematic reviews set forth by the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA),²⁸ the Peer Review Systematic Search Strategies (PRESS),²⁹ the Institute for Medicine Standards for Systematic Reviews,³⁰ and the Cochrane Handbook of Systematic Reviews.³¹ This study was registered on PROSPERO (#CRD42022321649) prior to data abstraction and exempt from institutional board review as only deidentified data derived from prior publications were included.

A medical librarian (A.H.) searched published literature for records discussing postpartum depression, anxiety, or distress and digital or mobile health interventions in pregnant or postpartum people. The librarian created search strategies using a combination of controlled vocabulary and keywords in Ovid Medline 1946-, Embase 1947-, Scopus 1823-, Cochrane

Database of Systematic Reviews (CDSR), Cochrane Central Register of Controlled Trials (CENTRAL), and [Clinicaltrials.gov](#) 1997-. The search was initially completed in October 2021 and was re-executed in December 2022. Appendix 1 describes reproducible search strategies for each database.

Study selection

Two co-authors (A.K.L and A.R.W) independently screened all titles and abstracts before jointly reviewing their individual selection of potentially eligible abstracts. Disagreements on potential eligibility were resolved with discussion with a third author (N.K.A.). A.K.L and A.R.W then independently reviewed all full-text articles for inclusion, with N.K.A determining final eligibility in cases of discrepancy. Review articles, case reports or series, abstracts, articles published in languages other than English, and studies without a comparison group or without outcomes of interest were excluded. Randomized trials comparing any perinatal digital health intervention to TAU, defined as routine care, were included. We also reviewed the bibliographies of included studies to identify additional eligible studies not identified in our search of the literature.

Data abstraction

Two authors (A.K.L and A.R.W.) independently reviewed eligible articles for data abstraction using a data abstraction tool (Appendix 2). The primary outcome was the score obtained on the first postpartum ascertainment after intervention delivery or randomization of depressive or anxiety symptoms using any psychometric scales that screen for PPD or PPA. For the secondary psychological outcomes, only studies that assessed PPD or PPA via the most commonly utilized psychometric scale for PPD (Edinburgh Postnatal Depression Scale (EPDS)³²) and for PPA (Generalized Anxiety Disorder-7 (GAD-7)³³) were included. Other secondary outcomes included screening positive at any postpartum assessment for depression or anxiety—as defined in the primary study—and loss to follow-up, defined as the proportion of participants who completed the final study assessment compared to the number who were initially randomized.

The same two reviewers also assessed the quality of each study using a prespecified criteria adapted from the Cochrane Handbook³¹ in a system of classification previously utilized.^{34–36} High-quality studies were defined as trials with appropriate randomization methods, clear definitions of primary outcomes, and intention-to-treat analyses. Lower-quality studies were those missing at least one of these attributes.^{34–36} In instances that a study did not include sufficient data to judge an attribute, that attribute was categorized as missing. Disagreement on study quality classification were resolved by discussion with a third author (N.K.A.).

Data synthesis and assessment of risk of bias

All statistical analyses were performed with the METAN package in STATA 16.0 (StataCorp LP, College Station, TX). Heterogeneity between studies was assessed using the Cochrane's Q and Higgins \hat{I}^2 tests.³¹ Heterogeneity was deemed to be significant based on conservative thresholds of $Q > df$ for the Q tests or $\hat{I}^2 > 30\%$.³¹ Raw data from each study were pooled. For continuous outcomes, the Hedges method was used to obtain standardized mean differences (SMD) when the studies used different psychometric scales, weighted mean

differences (WMD) were calculated when studies used the same psychometric scales. For categorical outcomes, pooled relative risks (RR) and 95% confidence intervals (CI) were calculated using raw data from each study. To account for clinical heterogeneity between studies and to produce a more conservative estimate of effect size,³⁷ data were pooled using the DerSimonian-Laird random-effects models regardless of evidence of statistical heterogeneity. For the primary outcomes (PPD and PPA), we also calculated 95% prediction intervals (PI) to determine the potential effect size of a new study if this study were selected at random from the same population of studies currently included in our meta-analysis.³⁸

We conducted pre-specified stratified analyses to assess whether the effect of the digital health intervention was altered by study quality, developed versus developing country setting, or type of digital health intervention. These analyses were based on study quality (higher- versus lower-quality), location of study completion (developed versus developing country, as categorized by the United Nations 2022 World Economic Situation and Prospects document³⁹), or route of digital health intervention delivery (online/internet versus TAU; app versus TAU; and text message/SMS versus TAU). In addition, we conducted stratified analyses based on: (1) whether the study population was restricted to those who screened positive for PPD or PPA per study criteria (i.e., either via a prespecified score on a PPD or PPA psychometric scale or self-reported depression or anxiety symptoms) or who were diagnosed with depression via formal psychological interview prior to randomization; and (2) the type of intervention delivered digitally (psychotherapy—defined as CBT, IPT, or mindfulness—or psychoeducation, with or without peer support; the study that provided peer support alone⁴⁰ was analyzed individually).

Publication bias was assessed visually using a funnel plot, while the Egger's test statistically assessed symmetry.⁴¹

Pooled Results

Study Selection

The literature search including [ClinicalTrials.gov](#) yielded a total of 921 citations. 453 duplicate citations were removed using the automatic duplicate finder in Endnote, and an additional 40 duplicates identified in both the original and updated search were removed (Figure 1). The titles and abstracts for each of the remaining 428 citation were reviewed for relevance and screened against inclusion and exclusion criteria. Most studies were excluded because they were not a randomized controlled trial (116 studies) or were a published study protocol (162 studies). Ultimately, 51 full texts were reviewed. Of these, 20 were excluded, most commonly because data were un-abstractable due to being presented as the change between psychometric scores at baseline and at first post-randomization assessment but without the actual scores (5 studies) or the study was described as a randomized trial but employed a different study design (4 studies) or lacked outcomes of interest (3 studies). Thus, 31 studies were included in the meta-analysis.

Study Characteristics

Baseline characteristics of included studies are described in Table 1. All 31 studies were randomized trials published as full-text manuscripts. One study dichotomized analyzes by parity (nulliparous and multiparous)²¹; data from this study were abstracted independently and presented in the forest plots as “Dol: nulliparous” and “Dol: multiparous” and was therefore counted as two studies in our analyses. Two studies were three-group randomized trials (in Jiao et al’s study,⁴² the three groups were: web-based psychoeducation, home-based psychoeducation, and TAU; for Milgrom et al’s study⁴³, the three groups were: web-based CBT, in-person CBT, and TAU). Per methodological strategies described in prior meta-analyses,^{34, 35} data from the DHI group and the TAU group were abstracted for these two studies and compared. Among the 31 studies, 20 were deemed to be of higher-quality,^{21, 22, 25, 27, 42–57} and 11 were lower-quality.^{19, 20, 23, 24, 26, 40, 58–62} The reason that a study was designated as lower quality is described in Table 1. 24 studies were conducted in developed countries^{19–22, 25–27, 42, 43, 45–53, 55, 56, 58–60, 62}; only seven were conducted in developing countries.^{23, 24, 40, 44, 54, 57, 61} The route of delivery for the DHI varied between studies: 19 studies utilized an online or internet-based intervention,^{20, 22, 24, 27, 40, 42, 43, 45–52, 55, 56, 58, 59} 11 studies employed a smartphone application,^{19, 23, 25, 26, 44, 53, 54, 57, 60–62} and one study used a text-message/SMS-based intervention.²¹ In terms of study population, 14 studies utilized DHIs to try to prevent PPD or PPA: of these, 10 studies did not include psychometric screening for or self-reported symptoms of depression and anxiety as part of their study’s eligibility criteria,^{19, 21, 23, 24, 40, 42, 44, 46, 50, 60} while four studies screened potentially eligible participants for depression or anxiety in order to exclude those who screened positive.^{22, 25, 27, 62} The remaining 17 studies utilized DHIs to try to treat PPD or PPA among those who screened positive or were diagnosed with PPD or PPA. Specifically, 12 studies included only those who screened positive for depression or anxiety prior to randomization,^{20, 26, 45, 52–59, 61} three studies included participants who underwent interview-based clinical assessments to diagnose major depressive disorder,^{43, 49, 51} and two studies included those who self-reported symptoms of depression or anxiety prior to randomization.^{47, 48} The type of intervention delivered digitally also varied: one provided digital peer support,⁴⁰ two delivered psychoeducation with peer support,^{51, 60} and nine provided psychoeducation.^{21, 23, 42, 44, 46, 47, 53, 62} Of the 20 studies that provided psychotherapy, 14 delivered CBT,^{20, 25–27, 43, 45, 48–52, 55, 59, 61} six provided mindfulness,^{19, 22, 24, 54, 57, 60} one delivered IPT,⁵⁶ and one included a program combining mindfulness and CBT.⁵⁸

Synthesis of results and risk of bias of included studies

In total, 5532 participants received a digital health intervention and 5492 participants received TAU across the 31 individual studies (which were analyzed as 32 studies due to Dol et al’s dichotomous study population²¹), with sample sizes ranging from 18 to 2509 participants and follow up lasting from 2 days until one year after randomization. Inclusion and exclusion criteria differed significantly across studies; for example, most studies recruited participants exclusively in person during prenatal care clinics or birth hospitalization while 7 studies recruited participants partly or exclusively through social media or printed advertisements in community space. The time frame of the first screen for PPD or PPA was heterogeneous: though 28 studies first assessed for PPD or PPA from four

Author Manuscript
Author Manuscript
Author Manuscript
Author Manuscript

to 12 weeks postpartum, the range extended from less than one week after delivery to 32 weeks postpartum.

Psychometric scales utilized to screen for PPD or PPA varied across studies (Table 1). Of the 29 studies that screened for PPD, 22 studies used the EPDS, three used the Patient Health Questionnaire-9,⁶³ two used the Depression subscale of the Depression, Anxiety, and Stress Scale-21 (DASS-21),⁶⁴ and two used the Beck's Depression Inventory.⁶⁵ Four studies presented data on screen-positive rates for PPD (though the definition of screening positive differed across studies: one study screen-positive PPD as having a mild score or higher on the DASS-21,¹⁹ and the three other studies used the EPDS, with a score of 9²⁴ or 10^{46,56} defined as screen positive). For PPA, six of the 17 studies that screened for PPA utilized the GAD-7, six used the anxiety subscale of the DASS-21,⁶⁴ two used the State Trait Anxiety Inventory,⁶⁶ Dol et al used the Postpartum Specific Anxiety Scale for the nulliparous and multiparous cohorts,⁶⁷ and one use the Hospital Anxiety and Depression Scale.⁶⁸ Only one study provided data on screen-positive rates for PPA, defined as a mildscore or more on the DASS-21 anxiety subscale.¹⁹

Compared to TAU, digital health interventions significantly, though modestly, reduced both PPD symptoms (29 studies: SMD -0.64 (95% CI: -0.88, -0.40); 95% prediction interval: -1.93, 0.65) and PPA symptoms (17 studies: SMD -0.49 (95% CI: -0.72, -0.25); 95% prediction interval: -1.96, 0.49) (Figure 2). A high amount of interstudy heterogeneity was identified for both PPD and PPA (I^2 was 94.4% and I^2 83.4%, respectively). For both primary outcomes, the funnel plots did not show asymmetry, and the Egger's test confirmed an absence of publication bias for PPD ($p=0.12$) and PPA ($p=0.85$) (Figure 3).

Secondary outcomes shown in Figure 4 include scores on the EPDS for PPD and on the GAD-7 for PPA as well as screen positive rates and overall loss-to-follow-up rates. When analyses were limited to studies that conducted PPD or PPA screening with these scales, DHIs significantly reduced both EPDS scores (22 studies: WMD -0.64 (95% CI -0.92, -0.35)) and GAD-7 scores (6 studies: WMD -0.52 (95% CI -0.78, -0.25)), though interstudy heterogeneity persisted (I^2 95.6% for PPD and I^2 59.5% for PPA). There were no differences in rates of screening positive for PPD (n=4) or PPA (n=1) among those randomized to DHI versus TAU. In terms of LTFU, 57.1% (n=3158) of those randomized to the DHI completed the final study assessment, compared to 66.2% (n=3635) of those randomized to TAU; thus, those randomized to the DHI had 38% higher risk of not completing the study comparatively (pooled RR 1.38 (95% CI 1.18, 1.62)).

Forest plots for stratified analyses or primary outcomes and for all secondary outcomes are included in Appendix 3. In general, the effect of DHIs on primary and secondary psychological outcomes was similar among the primary analyses and analyses stratified by study quality, country setting, type of DHI (web/online, app, or text message), and whether the participants did or did not screen positive (or was diagnosed with or self-reported symptoms of) depression or anxiety (Table 2). Nearly all stratified analyses showed high amount of inter-study heterogeneity (Table 2). For the primary PPD outcome, interventions that provided psychotherapy had a larger effect on PPD and PPA compared to those that delivered psychoeducation with or without peer support (psychotherapy: PPD (19 studies):

SMD -0.87 (95% CI: $-1.26, -0.48$) and PPA (11 studies): SMD -0.60 (95% CI: $0.91, -0.30$) versus psychoeducation: PPD (9 studies): SMD -0.15 (95% CI: $-0.22, -0.06$) and PPA (6 studies): SMD -0.29 (95% CI $-0.57, 0.00$). The risk of not completing the final study assessment was higher among those randomized to DHI that were web/online-based (19 studies: RR 1.77 (95% CI $1.46, 2.15$)) or that delivered psychotherapy (20 studies: RR 1.52 (95% CI $1.22, 1.90$) compared to the overall (RR 1.38 (95% CI $1.18, 1.62$)). Of note, there was no difference in loss to follow-up rates among those randomized to apps versus to TAU (RR 1.04 (95% CI: $0.91, 1.19$)).

Discussion

Principal Results

In this meta-analysis of randomized trials analyzing the effect of DHIs on PPD and PPA, a modest but statistically significant reduction in scores on psychometric scales assessing PPD and PPA were identified among those randomized to DHIs overall and when PPD and PPA were assessed via EPDS or GAD-7, respectively. This effect was more pronounced when the DHI delivered psychotherapy (CBT, IPT, or mindfulness) compared to psychoeducation with or without peer support. DHIs had similarly modest effect on preventing PPD or PPA from those who screened negative (or were not screened) for these conditions upon randomization and on treating PPD and PPA for those who screened positive or were diagnosed with depression or anxiety at randomization. Though LTFU rates were higher among those randomized to DHIs than those randomized to TAU, this difference was driven by a high rate of drop out identified in studies utilizing web/online interventions: there was no difference in LTFU rates among those randomized to apps compared to TAU. These findings suggest that, while all DHIs appear to improve postpartum mental health, those that provide psychotherapy and are delivered via smartphone application may be the most effective at improving psychological outcomes and retaining participant engagement, respectively.

Comparisons with Prior Work

Our findings are consistent with those reported from prior meta-analyses,^{15–18} which also noted a small but statistically significant improvement in psychometric scales measuring PPD or PPA but no difference in screen-positive rates for PPD among those randomized to DHIs compared to TAU. However, unlike the prior meta-analyses,^{15–18} which reported mostly pooled psychometric outcomes, we conducted stratified analyses based on factors that could plausibly impact the effectiveness of DHI, such as study quality, country of origin, type of intervention delivered (psychoeducation or psychotherapy), and type of DHI utilized (online, app, or SMS). In addition, unlike prior meta-analyses—which presented study populations as homogeneous^{15–18}—one of our analyses stratified the primary studies into those in which potential participants were required to screen positive for or self-reported depressive or anxiety symptoms in order to be randomized. Interestingly, this stratified analysis concluded that DHI had a similar effect on postpartum psychometric scales regardless of whether the participant did or did not screen positive for depression or anxiety. Altogether, our findings not only support those from prior meta-analysis^{15–18} but add depth to the relationship between DHI and postpartum depression and anxiety.

Clinical Implications

PPD and PPA are among the most common conditions in the postpartum period.^{1, 2} Despite the fact that psychoeducation³ and psychotherapy^{4–6} have been shown to effectively prevent and treat PPD and PPA, few people who have PPD or PPA are able to access these interventions,⁷ potentially due to a lack of skilled mental health professionals.⁸ DHIs are accessible to nearly all who reside in the United States,^{10–12} bypass barriers associated with reduced adherence to in-person postpartum care,^{13, 14} and are inherently scalable without relying on skilled mental health professionals for dissemination. The fact that DHIs are more effective than TAU in terms of reducing scores on psychometric scales assessing for PPD and PPA is promising for PPD/PPA prevention and treatment. More specifically, widespread incorporation of DHIs that provide evidence-based psychoeducation or psychotherapy could provide modest population-wide reductions in PPD and PPA symptoms, as measured by psychometric scales. Furthermore, the benefits to DHI noted in the subgroup of studies conducted in developing countries offers scalable promise to the global burden of untreated perinatal mental health conditions.

Strengths and Limitations

Our study offers several strengths. First, we used a predesigned protocol in which an expert research librarian conducted a comprehensive search strategy, and two researchers independently screened all abstracts and potentially eligible full manuscripts for inclusion before independently abstracting data, which reduced bias. We also updated our search during the review process due to the publication of multiple potentially eligible randomized trials after the initial search was complete, which allowed us to base our conclusions on the most up-to-date data available. In addition, we conducted multiple stratified analyses, which allowed us to assess the impact of study quality, study setting, type of intervention delivered, and type of DHI on the effectiveness of DHIs on PPD and PPA. Lastly, we pooled data from studies using random-effects models, which is a more conservative strategy that helps reduce the potential effect of heterogeneity between studies.

Nevertheless, limitations should be considered. First, the findings of our meta-analysis carry forward the limitations of primary studies, including lower quality studies. However, the persistence of our findings within the subgroup of studies considered high quality provides reassurance against biased findings. Second, there was excessive clinical and statistical heterogeneity in our analysis, with multiple different psychometric scales employed, varying eligibility criteria for entry into each included study, and the study interventions, even within similar categories of DHIs. We attempted to reduce the effect of this heterogeneity by conducting multiple secondary analysis and subgroup analysis in which the analyses were limited to studies that contained the same psychometric scale, or that required participants to screen positive for PPD, or used the same individual type of DHI. Though these additional analyzes may have reduced the effect of heterogeneity on our outcomes, it would be impossible to eliminate the heterogeneity, particularly for study intervention. Indeed, a trial analyzing the effect of self-guided online videos on CBT⁴⁵ and another trial analyzing the effect of a live, interactive, remote CBT workshop⁵⁵ were both categorized as a DHI offering online CBT, though these interventions clearly differed. Reframing the heterogeneity of DHIs included in this meta-analysis as mirroring differences between in-person CBT, IPT,

Author Manuscript
Author Manuscript
Author Manuscript
Author Manuscript

or mindfulness programs also reduces the potential effect of heterogeneity on our outcomes. Specifically, each psychotherapeutic intervention abides by defined principles within CBT, IPT, or mindfulness but is not identical to other programs offering the same psychotherapy. Third, the varying definitions of screening positive for PPD or PPA entailed—and the paucity of studies that included data on screening positive for either condition—limits our ability to examine the effect of DHIs on screen-positive PPD or PPA. Lastly, there was also marked heterogeneity in psychometric scales used in the primary PPD and PPA outcomes. Given the fact that our secondary outcomes were scores on one PPD or PPA scale and these analyses had similar results as from our primary analysis, it is unlikely that this heterogeneity affected our results.

Need for additional research

The fact that participants were more likely to not complete final study assessments if randomized to the DHI group than to the TAU group demonstrates that more research is needed to optimize acceptability and use of DHI in clinical settings. Incorporating end-user feedback into the intervention development process has been described as an effective strategy to encourage sustained participant engagement with DHIs.^{69–71} In addition, the notable difference in LTFU rates among online DHIs versus app-based DHIs—and in particular the lack of difference in loss-to-follow up rates among app-based DHIs and TAU—should be a research priority. Implementation research or hybrid implementation-effectiveness trials may offer another avenue to understand and optimize DHI use.⁷² Lastly, most studies included assessed PPD, but fewer assessed PPA. Future research on DHI should include assessments for both PPD and PPA.

Conclusions

The results from this meta-analysis of randomized trials suggest that DHIs significantly—though modestly—reduce PPD and PPA symptoms and that this effect is more pronounced if the DHI delivers psychotherapy such as CBT, IPT, or mindfulness. Though LTFU rates were higher overall among those randomized to DHIs than those randomized to TAU, there was no difference in LTFU rates among those randomized to apps compared to TAU. These findings suggest that DHIs that provide psychotherapy and are delivered via smartphone application may be the most effective at improving perinatal psychological outcomes and retaining participant engagement. However, because few studies include app-based psychotherapy, additional high-quality randomized trials are needed to further examine the potential of DHIs delivering psychotherapy via a smartphone application specifically on reducing PPD and PPA.

Appendix 1: Systematic Review Search Methodology

Search Strategies created by Angela Hardi, MLIS, Original search: October 2021; Updated Search: December 2022

Methods:

The published literature was searched using strategies designed by a medical librarian for the concepts of postpartum depression, anxiety, or distress, and mobile health applications. The strategies were created using a combination of controlled vocabulary terms and keywords, and were executed from database inception in Medline (Ovid), Embase.com, Scopus, CINAHL Plus, PsycInfo, Cochrane Library (including CENTRAL), and [Clinicaltrials.gov](#). Results were limited to randomized controlled trials by using RCT filters recommended by the Cochrane Group for Ovid-Medline¹, Embase,² and CINAHL,³ and a librarian-created filter for Scopus.⁴ Results were limited to English and Spanish using database-supplied limits. The initial searches were completed on October 7, 2021, with an updated literature search completed on December 6, 2022. A 2021–2022/2023 date limit was used on the updated literature search. Complete search strategies are provided.

Results:

The initial literature search completed in 2021 retrieved 614 search results. The citations were imported to Endnote where 304 duplicate citations were identified and removed leaving 310 unique citations for analysis. The updated literature search completed in 2022 retrieved 307 search results, with 189 duplicate citations, leaving 118 unique citations for analysis. Between the initial and updated literature searches there were 428 unique citations remaining for further review.

Mobile health interventions more effective than routine care in preventing or treating postpartum depression or anxiety: meta-analysis of randomized controlled trials

Study Title:			
Lead Author:			
Study period:	Publication Year:		
Abstract	Manuscript		
Lead Author Affiliation:	Physician	Nurse	Psychologist
Inclusion criteria:			
Exclusion criteria:			
Intervention: Psychoeducation	Psychotherapy:	Peer support	Other (define):
Intervention Delivery: Internet	Smartphone application	Short messaging system/Text	Conversational agent
When was intervention given to women (select all):	During pregnancy After delivery		
Study Setting (include country, and whether developed or developing):			
Single center:			
Multicenter:			
Primary outcome: Perinatal mental health outcomes	Feasibility/acceptability		
If primary outcome perinatal mental health, define:			
QUALITY METRIC (if all three present, HIGH quality. If 2 or fewer present, LOW quality)			
1) Randomization (describe):			
2) Intention-to-treat Analysis: Yes No			
3) Primary outcomes clearly defined?			

Overall loss to follow up (%):

GROUPS	Intervention (digital health), N=	Routine Care, N=
EXPOSURE (type of intervention & delivery)		
Frequency of intervention		
STUDY QUALITY		
Loss to follow up (%)		
OUTCOMES		
Depression & depression symptoms		
1. EPDS <u>Mean (SD)</u> <u>Median (IQR), total ranae</u>		
2. PHQ-9 <u>Mean (SD)</u> <u>Median (IQR), total ranae</u>		
3. Other scale (NAME) <u>Mean (SD)</u> <u>Median (IQR), total range</u>		
4. Psychologist/Psvch evaluation <u>metric used</u> # screen positive (%)		
5. Screen positive (i.e. dichotomous yes/ no scale) <u>scale used</u> # screen positive (%)		
Anxiety & anxiety symptoms		
1. EPDS <u>Mean (SD)</u> <u>Median (IQR), total ranae</u>		
2. State-Trait Anxiety Inventory <u>Mean (SD)</u> <u>Median (IQR), total ranae</u>		
3. Other scale (NAME) <u>Mean (SD)</u> <u>Median (IQR), total range</u>		
4. Psychologist/Psvch evaluation <u>metric used</u> # screen positive (%)		
5. Screen positive(i.e. dichotomous yes/ no scale) <u>scale used</u> # screen positive (%)		
Other psychometric symptoms assessed:		
1. Define condition and scale <u>Mean (SD)</u> <u>Median (IQR), total range</u> OR N (%)		
2. Psychologist/Psvch evaluation <u>metric used</u> # screen positive (%)		
Secondary Outcomes Feasibility		
1. Define scale <u>Mean (SD) vs Median (IQR), total range</u> OR N (%)		
Acceptability		
1. Define measure/scale <u>Mean (SD) vs Median (IQR), total</u>		

GROUPS	Intervention (digital health), N=	Routine Care, N=
EXPOSURE (type of intervention & delivery)		
range OR N (%)		

Data Abstractor: Adam Anna Nina

Appendix 3: Forest plots detailing stratified analyses of the effect of digital health interventions (DHIs) versus treatment as usual (TAU) on postpartum depression or postpartum anxiety

Table of Contents:

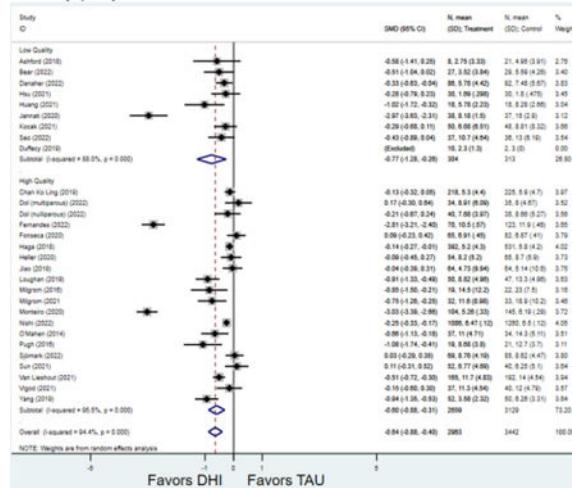

- 3A: Scores on postpartum depression scale; 3B: Scores on postpartum anxiety scale;
- 3C: scores on Edinburgh Postnatal Depression Scale; 3D: Scores on Generalized Anxiety Disorder-7 Scale; 3E: Loss-to-follow-up rates

Key for all forest plots:

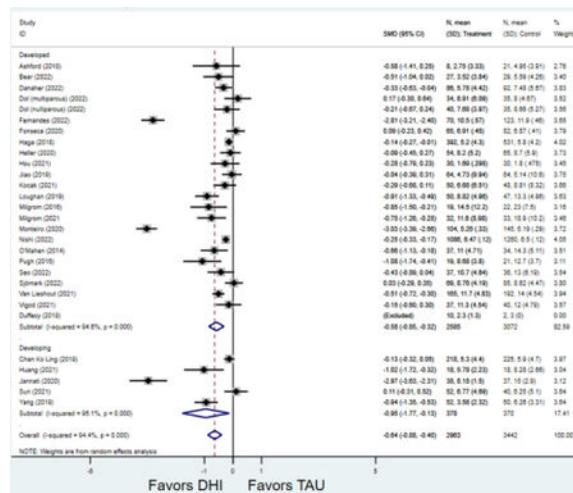

SMD = standardized mean difference. DHI = digital health intervention. TAU = treatment as usual. SD = standard deviation. LTFU = lost to follow-up. RR = relative risk. CI = confidence interval

3A: Scores on postpartum depression scale

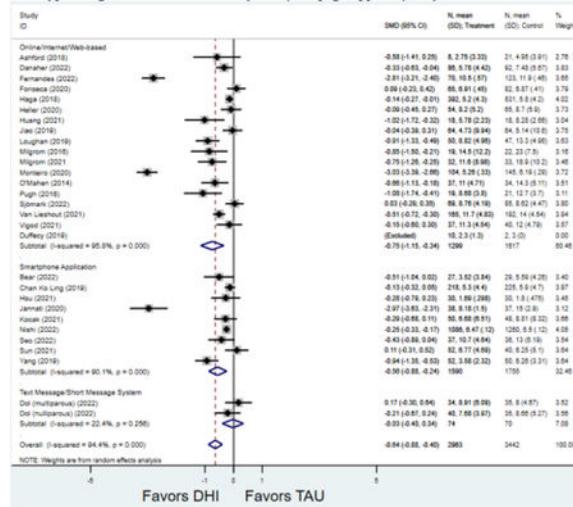

3A1: Study Quality

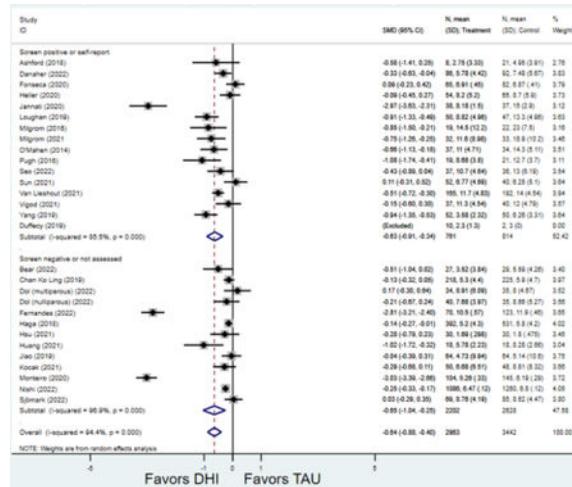

3A2: Country setting

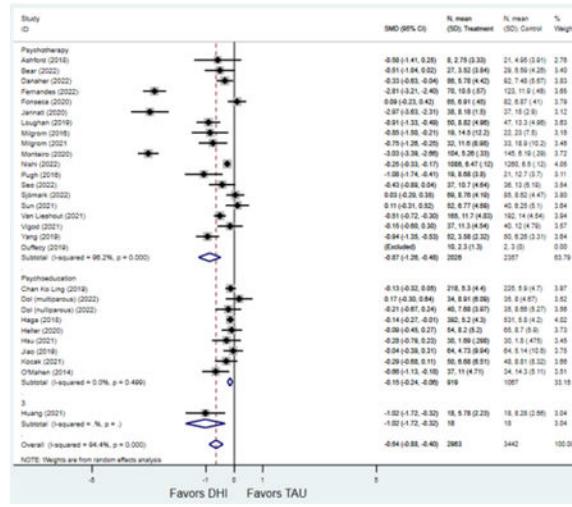

3A3: Type of digital health intervention (online/webpage, app, text/SMS)

3A4: Screen positive or self-reported symptoms versus screen negative or not assessed

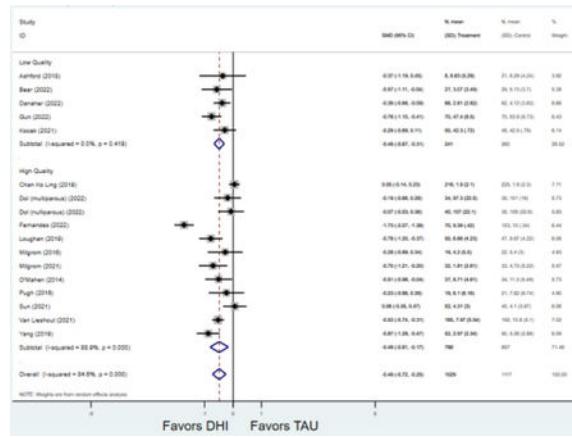

3A5: Type of intervention delivered (psychotherapy, psychoeducation with or without peer support)

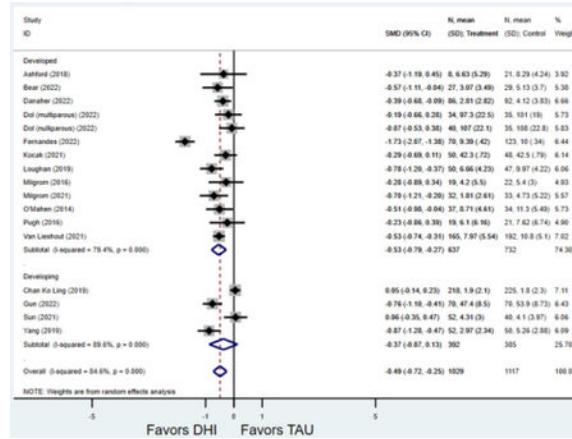

3B: Scores on postpartum anxiety scale

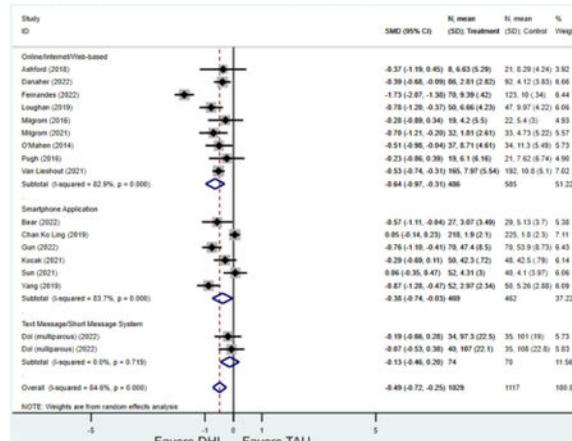

3B1: Study Quality

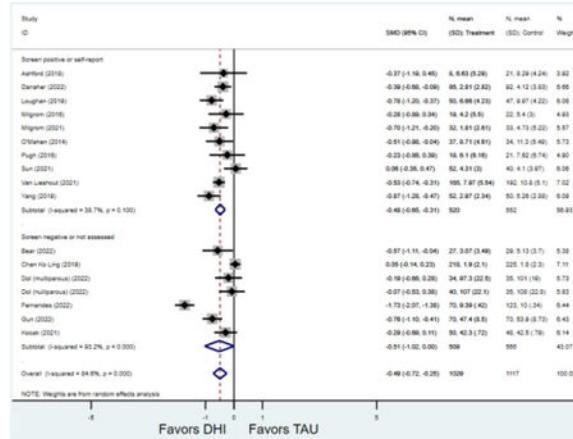

3B2: Country setting

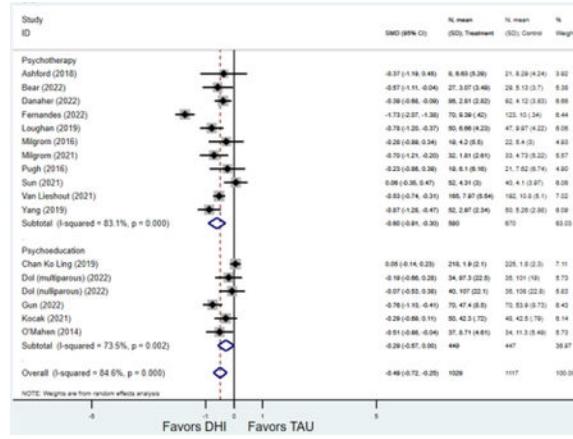

3B3: Type of digital health intervention (online/webpage, app, text/SMS)

3B4: Screen positive or self-reported symptoms versus screen negative or not assessed

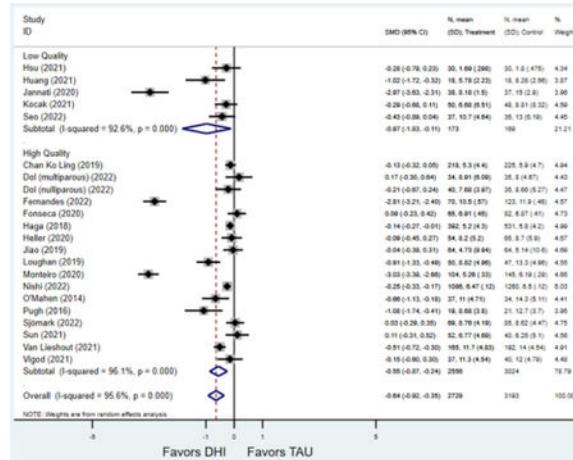

3B5: Type of intervention delivered (psychotherapy, psychoeducation with or without peer support)

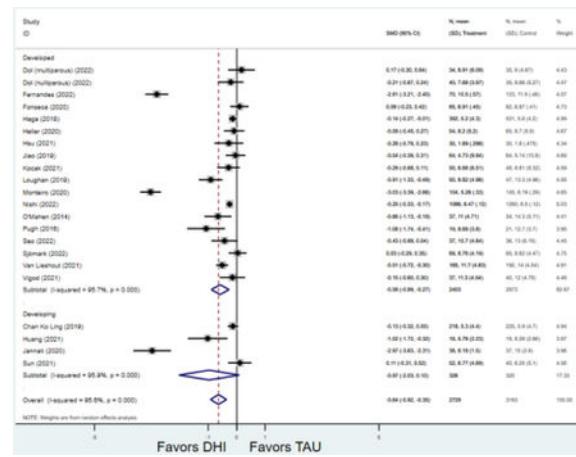

3C: Scores on Edinburgh Postnatal Depression Scale

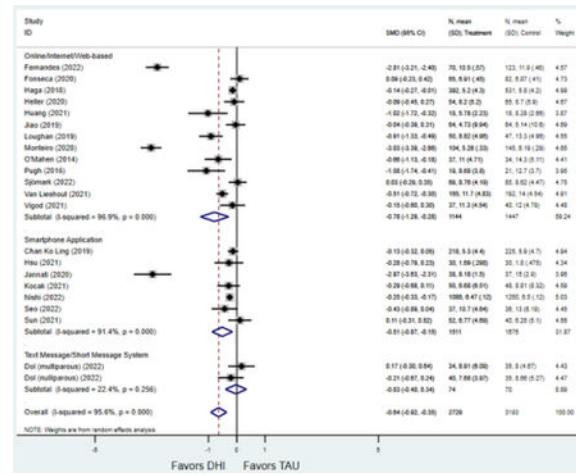

3C1: Study Quality

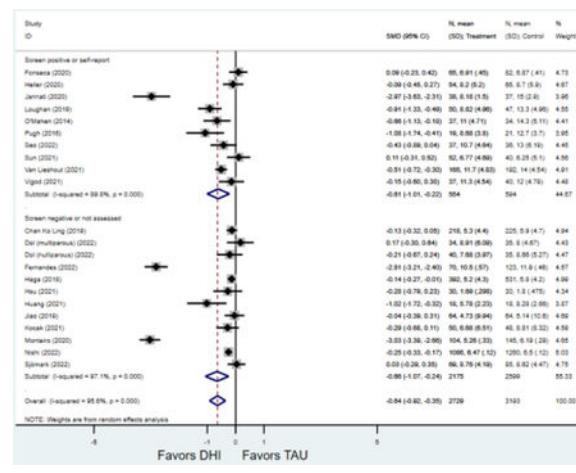

3C2: Country setting

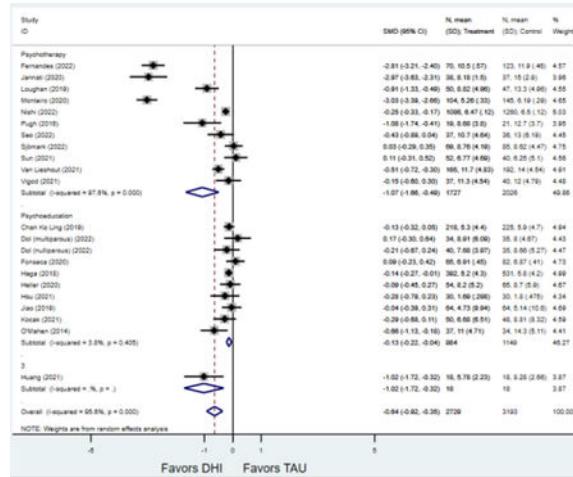

3C3: Type of digital health intervention (online/webpage, app, text/SMS)

3C4: Screen positive or self-reported symptoms versus screen negative or not assessed

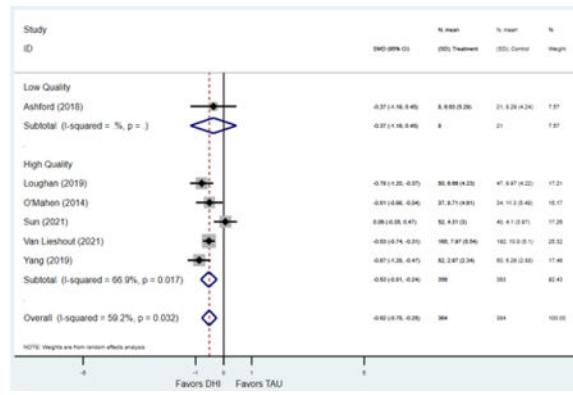

3C5: Type of intervention delivered (psychotherapy, psychoeducation with or without peer support)

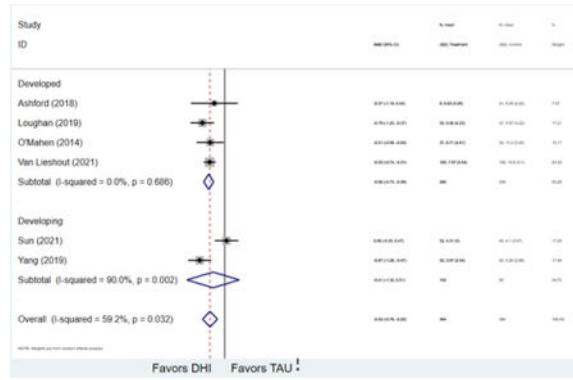

3D: Scores on Generalized Anxiety Disorder-7

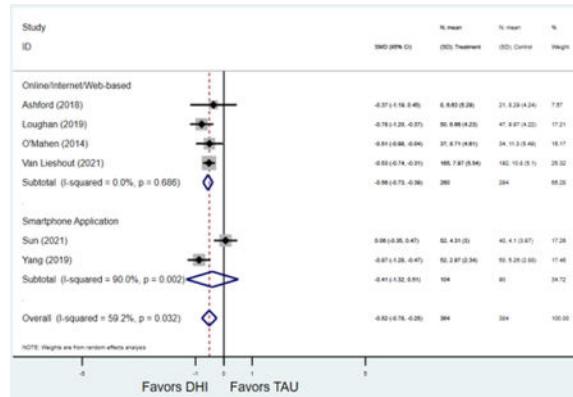

3D1: Study Quality

3D2: Country setting

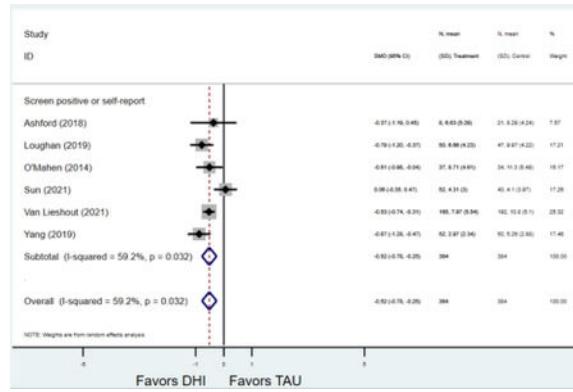

3D3: Type of digital health intervention (online/webpage, app, text/SMS)

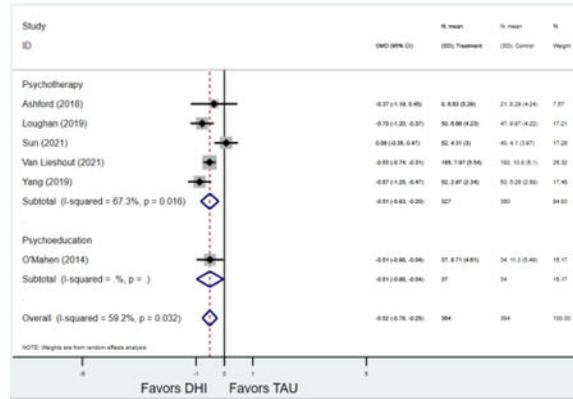

N.B. No observations for text-based DHI

3D4: Screen positive or self-reported symptoms versus screen negative or not assessed

3D5: Type of intervention delivered (psychotherapy, psychoeducation with or without peer support)

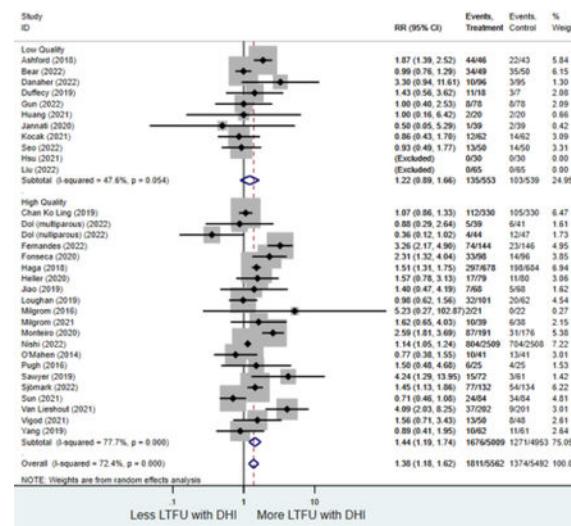

3E: Loss-to-follow up rates

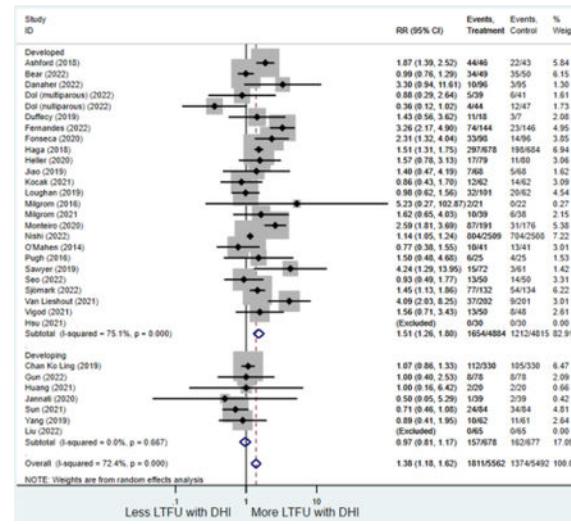

(those randomized who did versus did not complete final study assessment)

N.B.: Relative risks >1 suggest those randomized to DHI are more likely to NOT complete final study assessments.

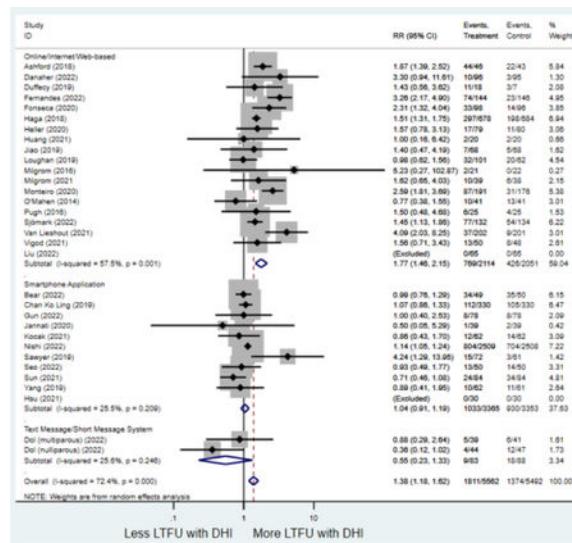

3E1: Study quality

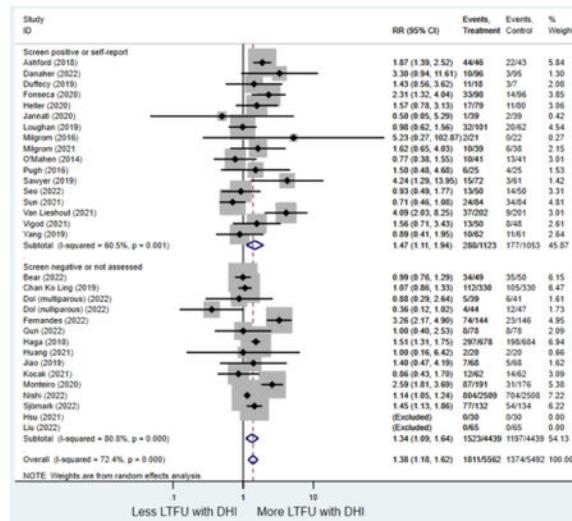

3E2: Country setting

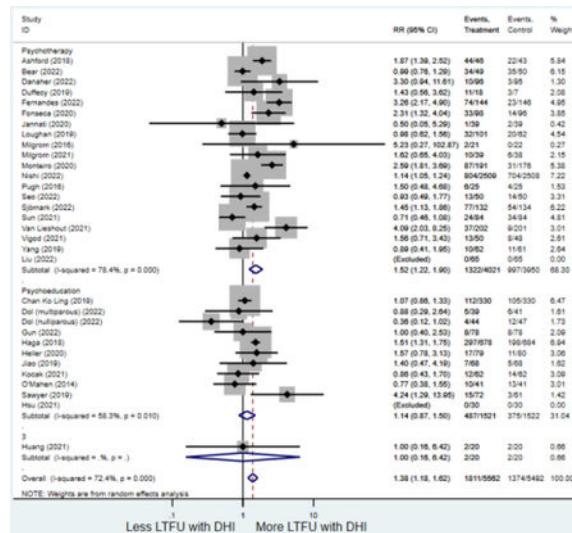

3E3: Type of digital health intervention (online/webpage, app, text/SMS)

3E4: Screen positive or self-reported symptoms versus screen negative or not assessed

3E5: Type of intervention delivered (psychotherapy, psychoeducation with or without peer support)

AJOG at a Glance

1. A. Why was this study conducted?
 - a. a. Digital health interventions (DHI) are increasingly utilized in postpartum depression (PPD) and postpartum anxiety (PPA) prevention and treatment.
 - b. b. Eight randomized controlled trials (RCTs) comparing DHI to treatment as usual for PPD and PPA have been published since the most recent meta-analysis
2. B. What are the key findings?
 - a. a. DHIs effectively but modestly reduce symptoms of PPD and postpartum anxiety overall, particularly when the DHI provides psychotherapy.
 - b. b. Those randomized to DHI had higher risk of loss-to-follow-up (LTFU) versus those randomized to TAU overall, but the rate of LTFU was similar among smartphone applications.
3. C. What does this study add to what is known?
 - a. a. App-based DHIs providing psychotherapy may be the most effective at improving perinatal psychological outcomes and retaining participant engagement.

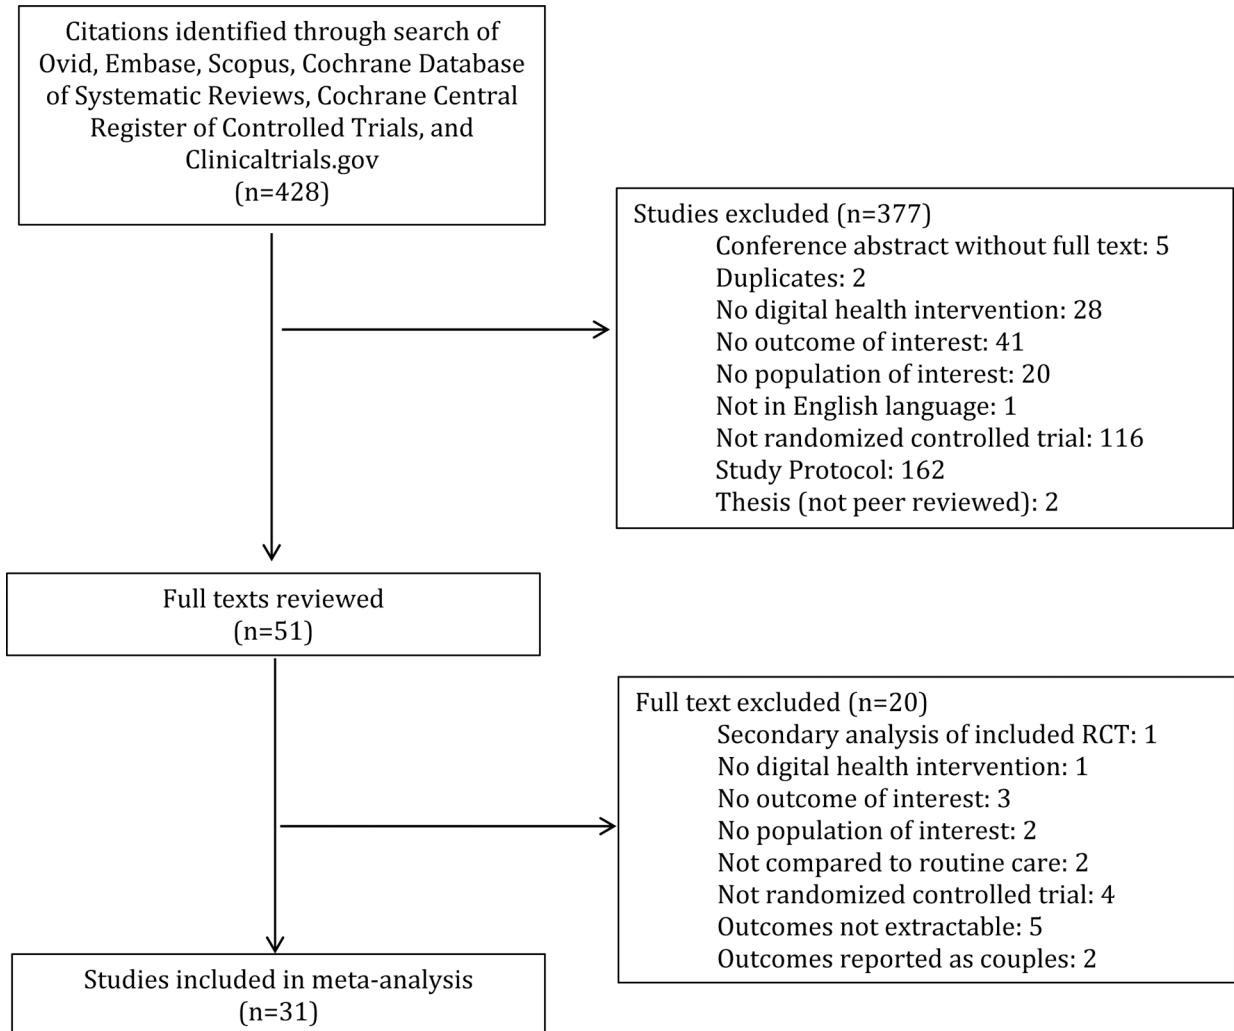

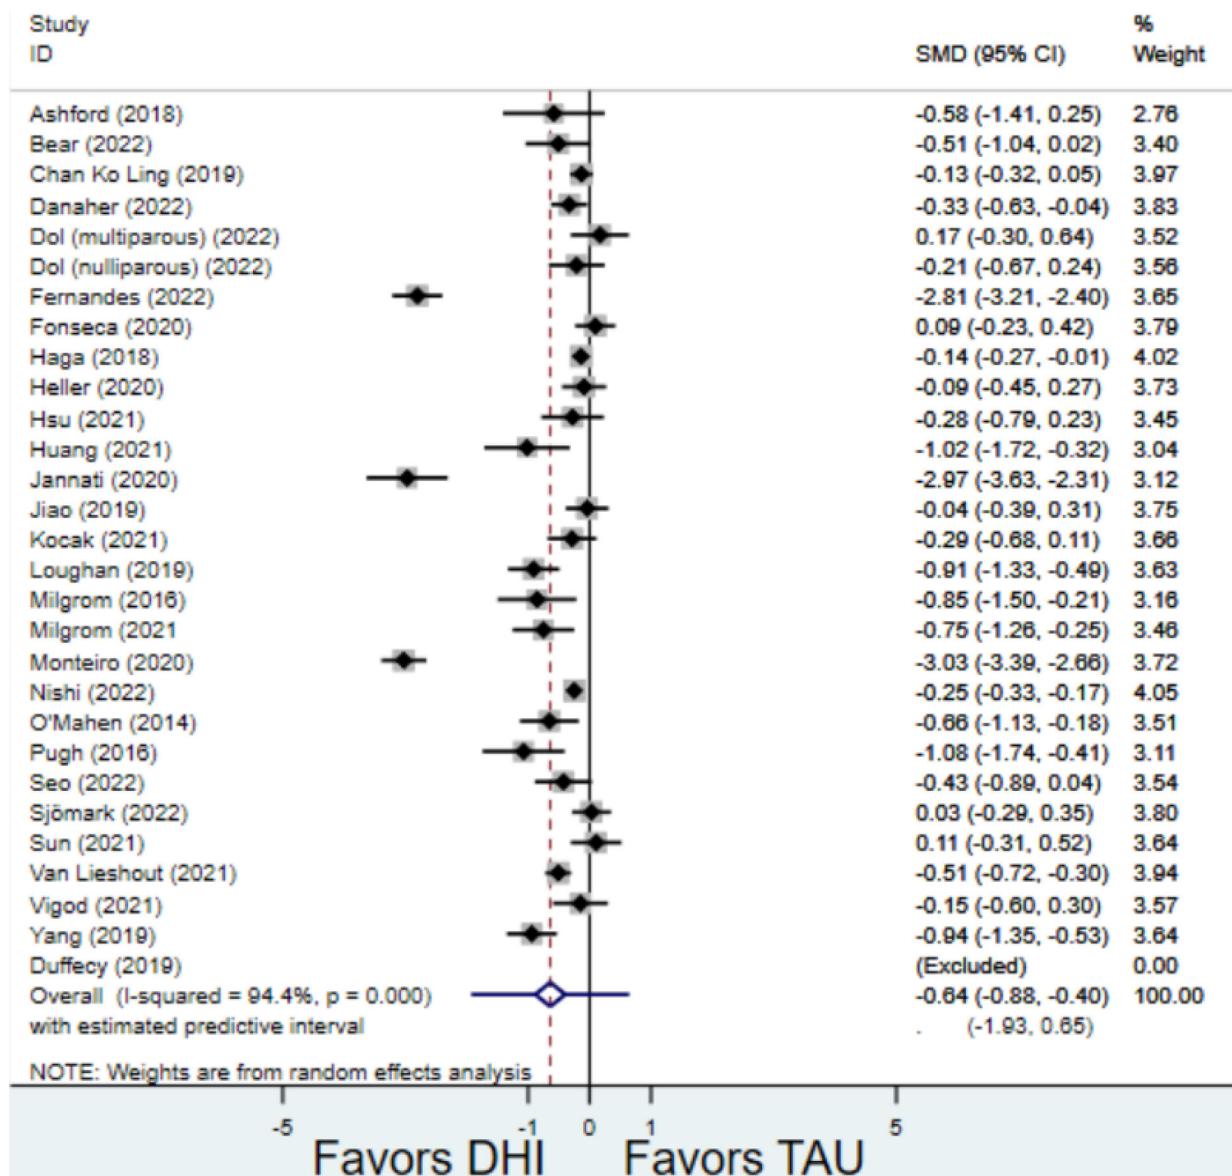

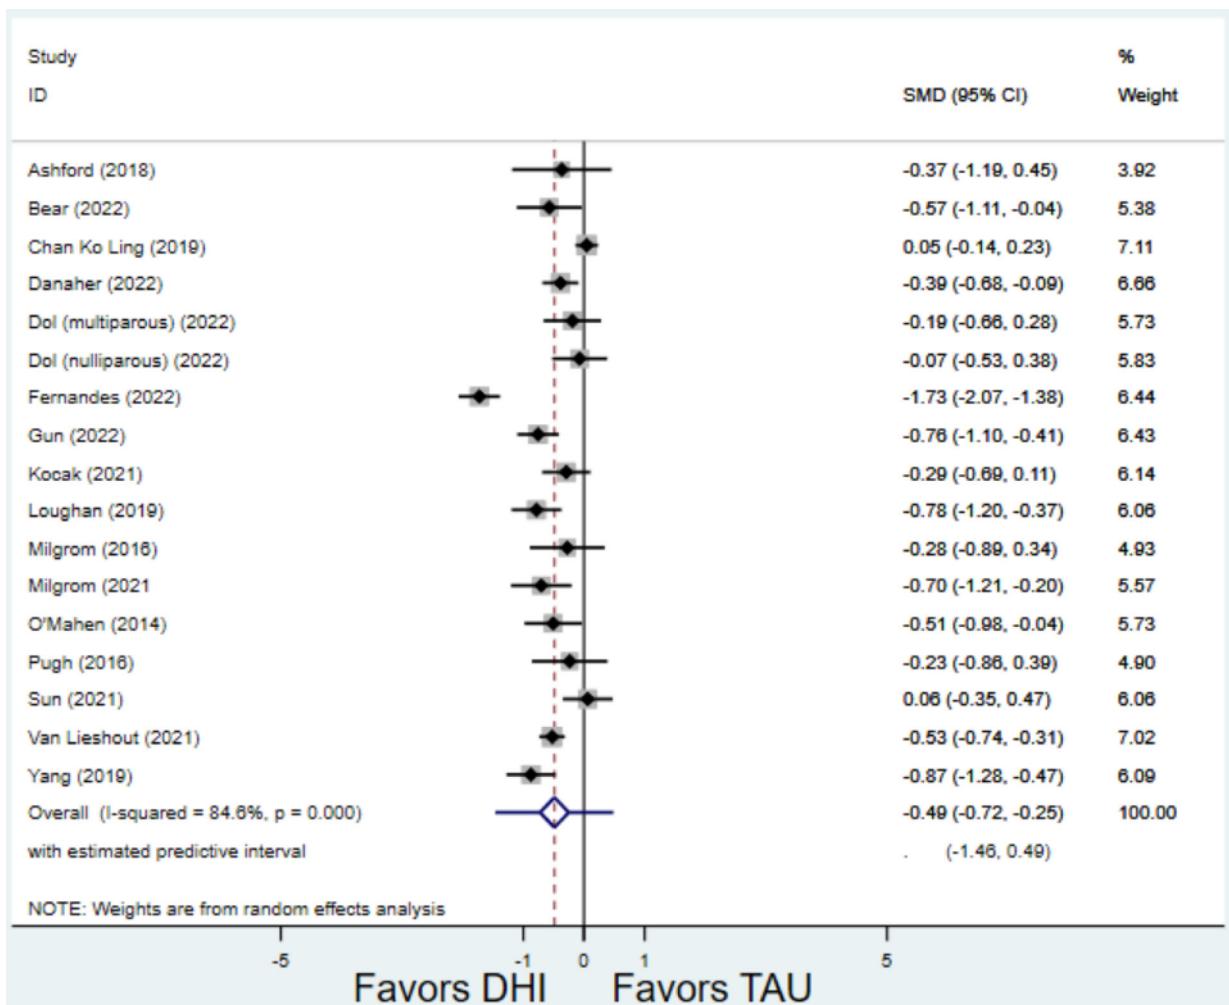

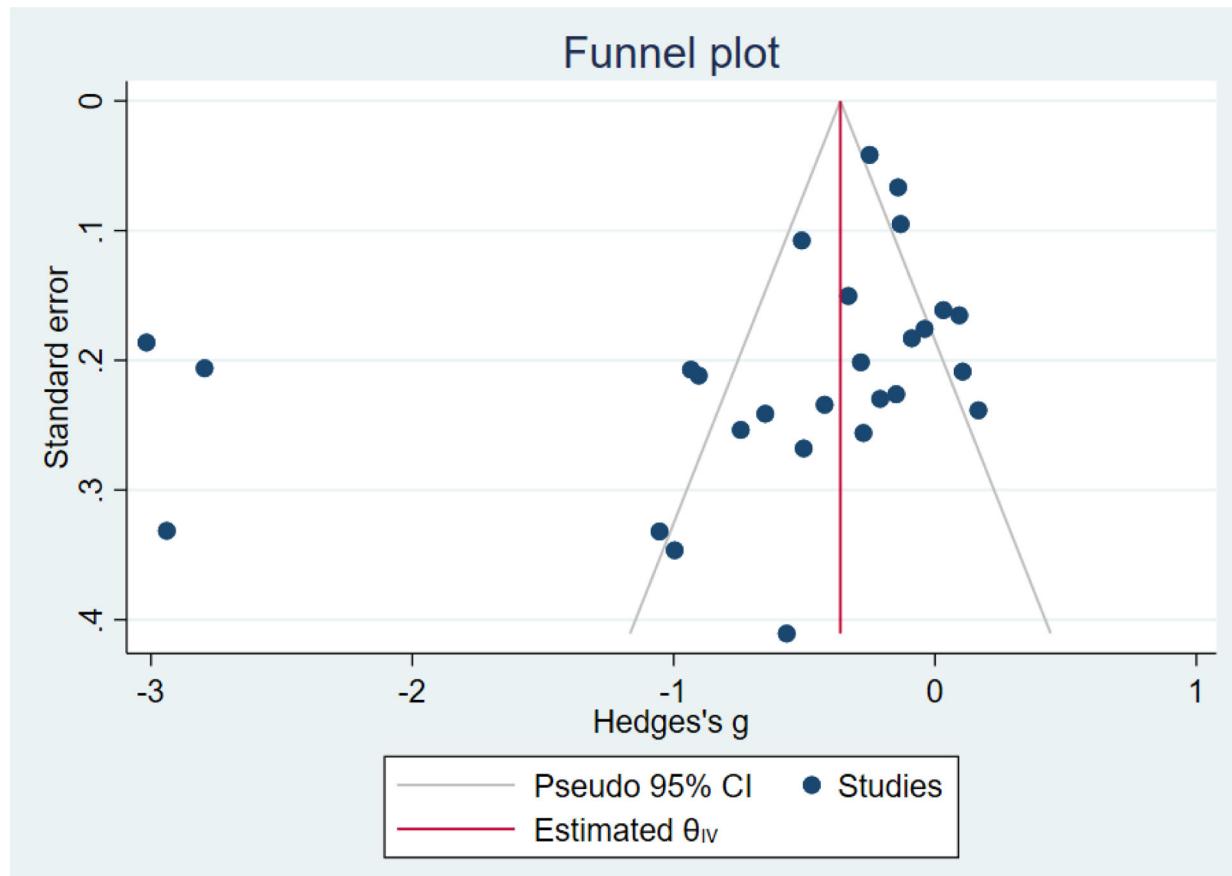

Figure 1:
Flow Diagram for Study Selection

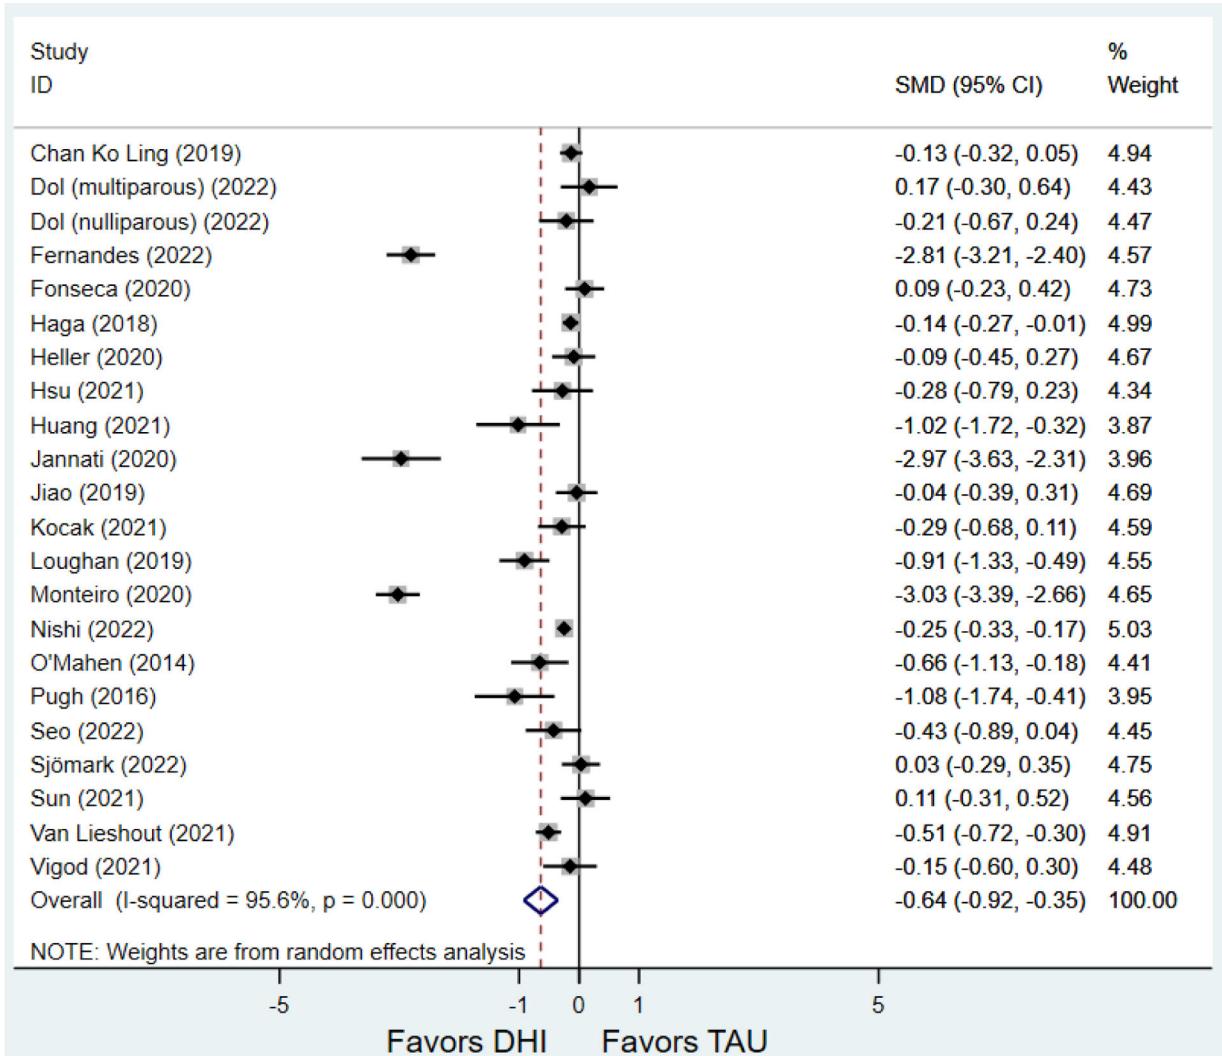

**Figure 2:**

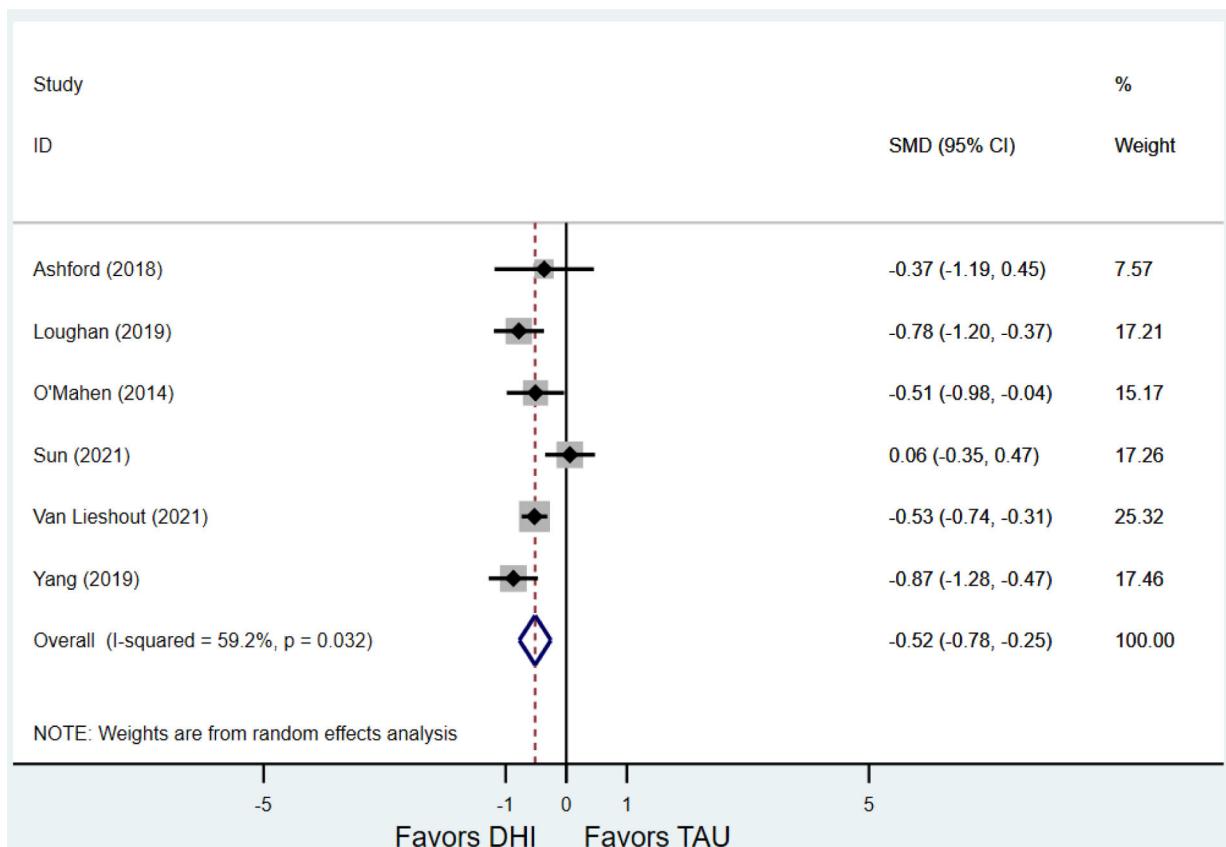

Weighted mean difference of scores of first postnatal screen for (a) postpartum depression and (b) postpartum anxiety after digital health intervention versus treatment as usual for postpartum depression or anxiety Key: DHI = digital health intervention; TAU = treatment as usual. SMD = standardized mean difference. PPD= postpartum depression. PPA = postpartum anxiety.

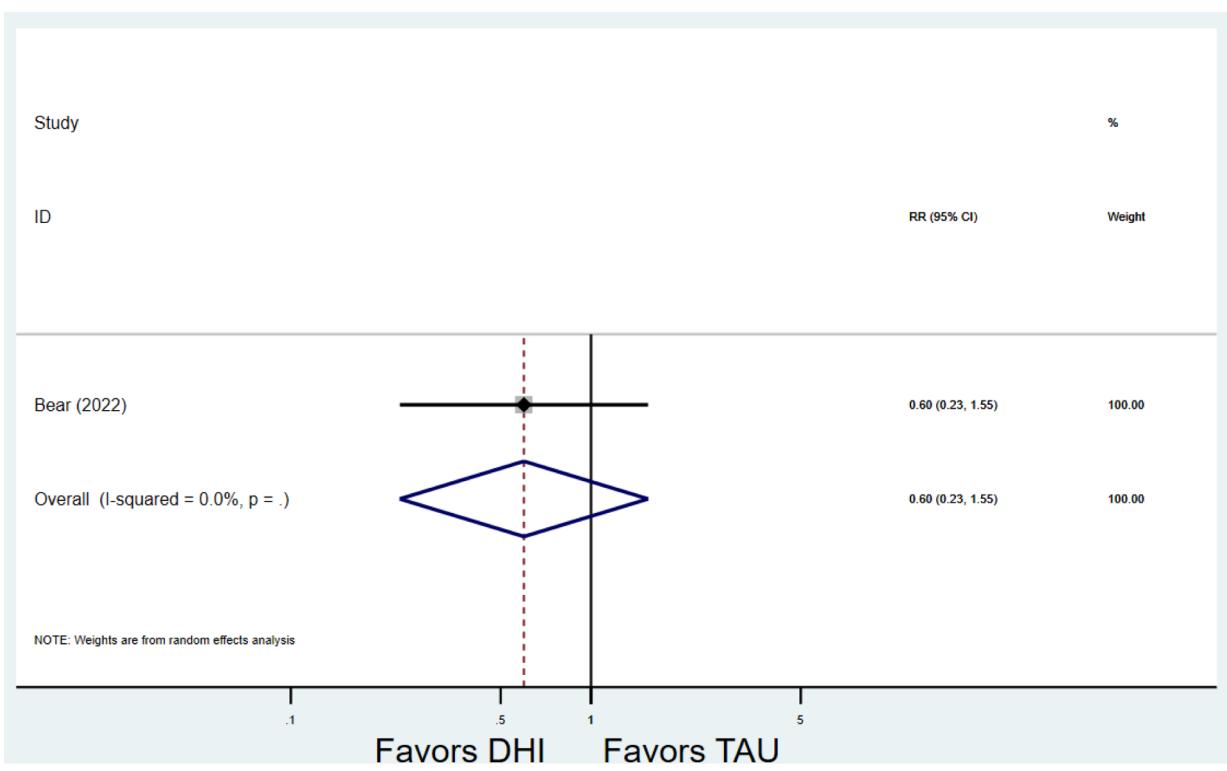

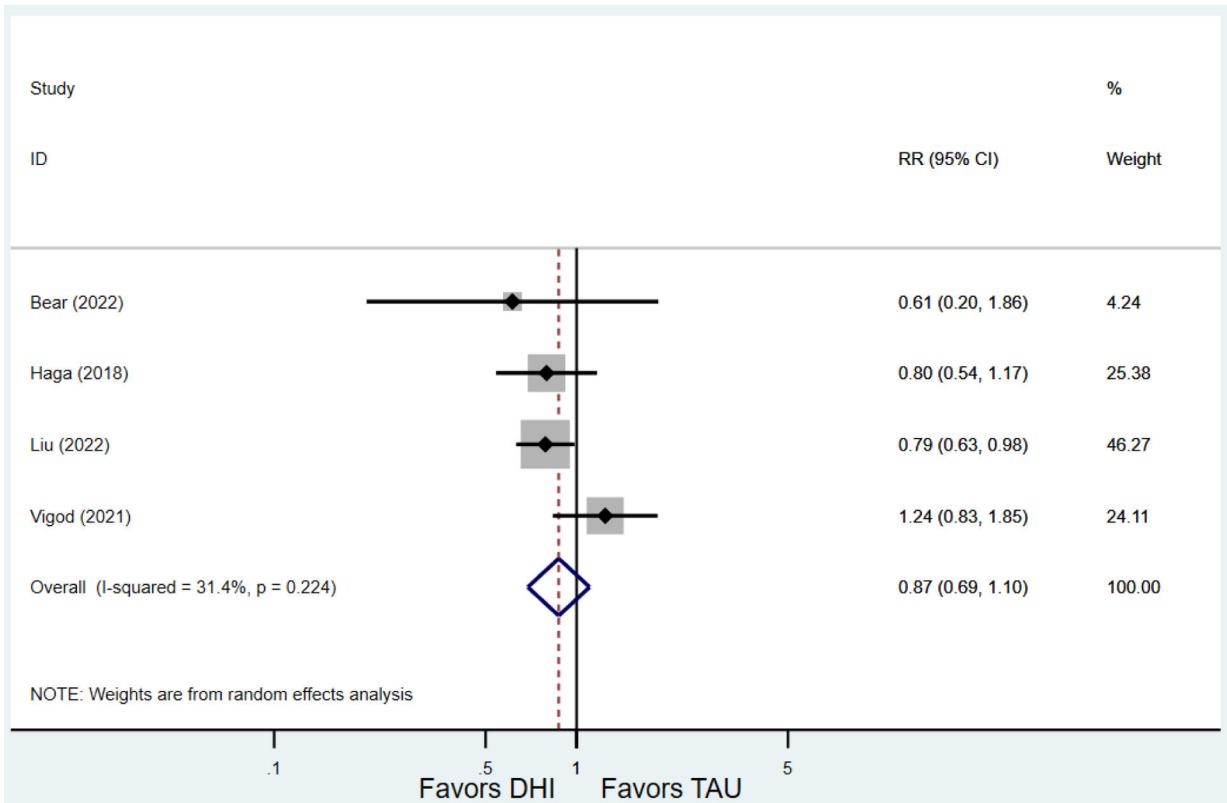

- a) Scores on first screening for PPD after delivery
- b) Scores on first screening for PPA after delivery

**Figure 3:**

Funnel plot with pseudo 95% confidence intervals for all studies included for postpartum depression screening

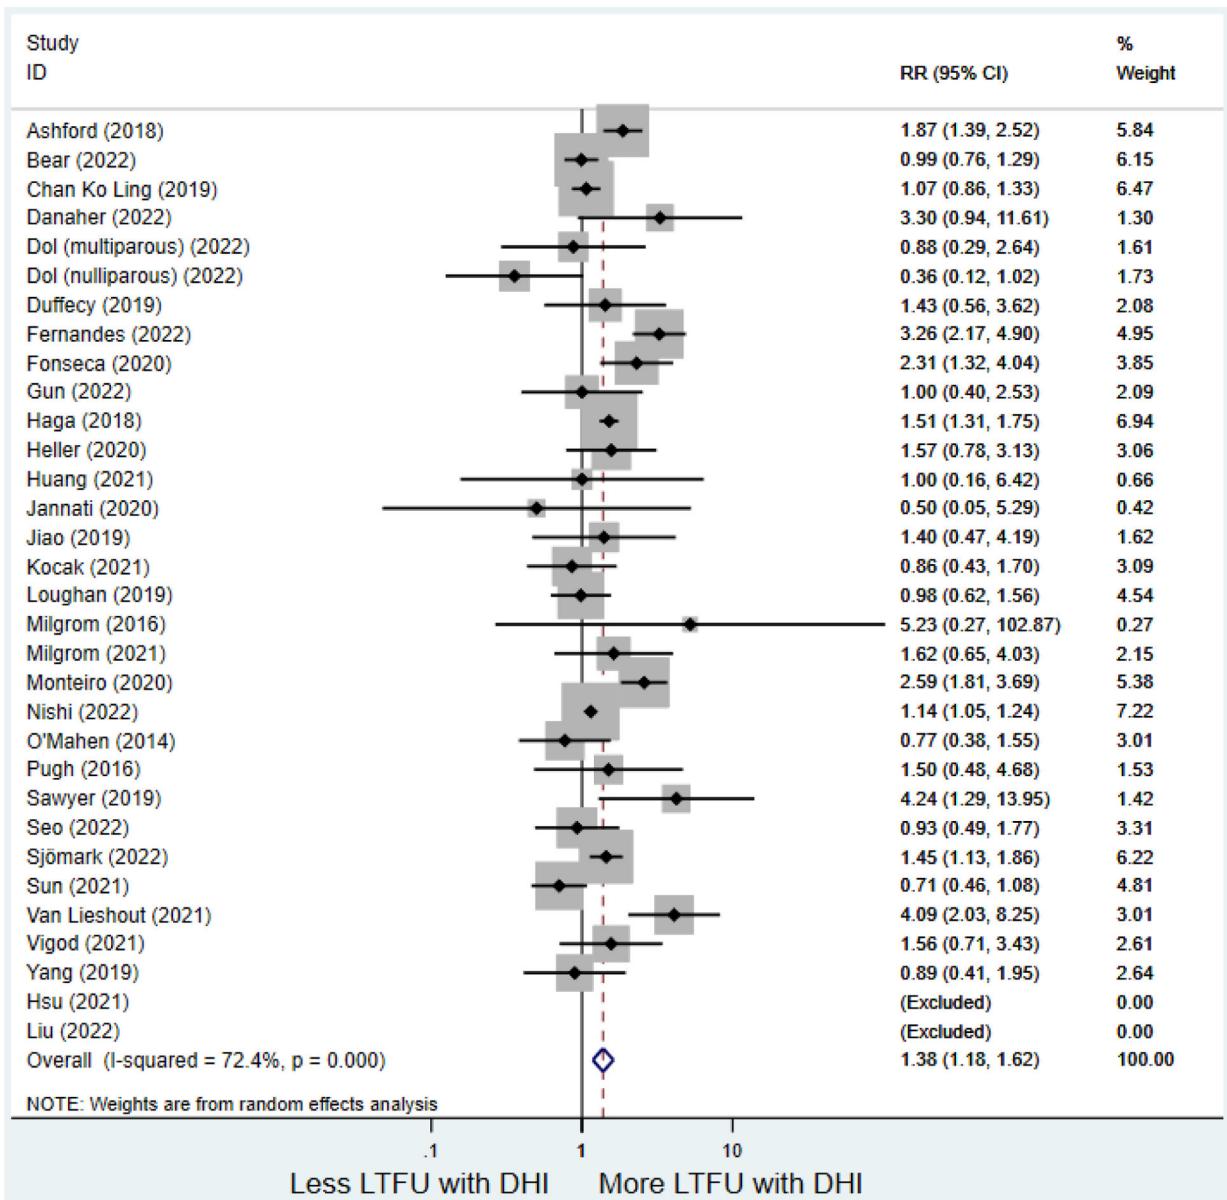

Figure 4:
Secondary outcomes after digital health intervention versus treatment as usual for postpartum depression or anxiety Key for all forest plots: DHI = digital health intervention. TAU = treatment as usual. SMD = standardized mean difference. CI = confidence interval. PPD = postpartum depression. PPA = postpartum anxiety. EPDS: Edinburgh Postnatal Depression Scale. GAD-7: Generalized Anxiety Disorder-7. LTFU: loss to follow-up.

- Scores on first EPDS screening for PPD after delivery
- Scores on first GAD-7 screening for PPA after delivery
- Screen positive for PPD
- Screen positive for PPA

e) Loss to follow-up rates
