Background: Glucagon-like peptide-1 receptor agonist (GLP-1RA), which is a therapeutic agent for the treatment of type 2 diabetes mellitus, has a beneficial effect on the cardiovascular system.

Methods: To examine the protective effects of GLP-1RAs on proliferation and migration of vascular smooth muscle cells (VSMCs), A-10 cells exposed to angiotensin II (Ang II) were treated with either exendin-4, liraglutide, or dulaglutide. To examine the effects of GLP-1RAs on vascular calcification, cells exposed to high concentration of inorganic phosphate (Pi) were treated with exendin-4, liraglutide, or dulaglutide.

Results: Ang II increased proliferation and migration of VSMCs, gene expression levels of Ang II receptors *AT1* and *AT2*, proliferation marker of proliferation Ki-67 (*Mki-67*), proliferating cell nuclear antigen (*Pcna*), and cyclin D1 (*Ccnd1*), and the protein expression levels of phospho-extracellular signal-regulated kinase (p-Erk), phospho-c-JUN N-terminal kinase (p-JNK), and phospho-phosphatidylinositol 3-kinase (p-Pi3k). Exendin-4, liraglutide, and dulaglutide significantly decreased the proliferation and migration of VSMCs, the gene expression levels of *Pcna*, and the protein expression levels of p-Erk and p-JNK in the Ang IItreated VSMCs. Erk inhibitor PD98059 and JNK inhibitor SP600125 decreased the protein expression levels of Pcna and Ccnd1 and proliferation of VSMCs. Inhibition of GLP-1R by siRNA reversed the reduction of the protein expression levels of p-Erk and p-JNK by exendin-4, liraglutide, and dulaglutide in the Ang II-treated VSMCs. Moreover, GLP-1 (9-36) amide also decreased the proliferation and migration of the Ang II-treated VSMCs. In addition, these GLP-1RAs decreased calcium deposition by inhibiting activating transcription factor 4 (Atf4) in Pi-treated VSMCs.

Conclusion: These data show that GLP-1RAs ameliorate aberrant proliferation and migration in VSMCs through both GLP-1Rdependent and independent pathways and inhibit Pi-induced vascular calcification.

INTRODUCTION

Cardiovascular disease (CVD) includes all disorders of the heart and blood vessels, such as coronary heart disease, ischemic heart disease, hypertension, stroke, and atherosclerosis, and is a major cause of mortality and morbidity among patients with diabetes [1,2]. The risk for CVD morbidity and mortality is 2 to 4-fold higher in patients with type 2 diabetes mellitus (T2DM) than in those without diabetes, and the prevalence of T2DM is steadily increasing worldwide [3].

Atherosclerosis is a chronic disease associated with the interaction between lipid metabolism and inflammation [4,5]. The atherosclerotic process is initiated by the accumulation of lowdensity lipoprotein (LDL) cholesterol, which causes vascular smooth muscle cell (VSMC) injury. In atherosclerosis, lipid accumulation induces transdifferentiation of VSMCs into alternative phenotypes such as macrophage-like, foam cell-like, and osteochondrogenic-like, which contribute to plaque progression [6,7]. In addition, VSMCs are involved in all developmental and progression stages of atherosclerosis, through migration, proliferation, and apoptosis. Aberrant proliferation and migration of VSMCs following phenotypic switching are hallmarks of atherosclerosis [4,8].

Angiotensin II (Ang II) is the effector peptide of the reninangiotensin system and is implicated in endothelial dysfunction, atherosclerosis, hypertension, and related vascular diseases [9]. The effects of Ang II are mediated through two receptor subtypes: the angiotensin II receptor type 1 (AT1), which is involved in inflammation, proliferation hypertrophy, and vasoconstriction; and the angiotensin II receptor type 2 (AT2), which is involved in apoptosis, hypotension, and vasodilation [10,11]. The AT2 receptor inhibits the AT1 receptor [12,13], and the ratio of AT1 to AT2 is closely related to the cardiovascular complications associated with diabetes [14]. In addition, AT1 antagonists inhibit VSMC proliferation and migration via the adenosine monophosphate-activated protein kinase (AMPK)/mammalian target of rapamycin (mTOR) signaling pathway [15].

Vascular calcification is the deposition of minerals in the artery walls, and it is closely related to CVDs [16,17]. Previous studies reported that intimal calcification is associated with atherosclerosis, while medial calcification is associated with diabetes, chronic kidney disease, and aging [18,19]. VSMCs are the most abundant component of the middle layer of the artery wall, and the transdifferentiation of VSMCs by a high concentration of inorganic phosphate (Pi) is one of the major pathways leading to medial calcification [20].

Glucagon-like peptide-1 receptor agonists (GLP-1RAs) are glucose-lowering medications used in the treatment of T2DM. GLP-1 receptor (GLP-1R) expression is detected in various cardiovascular tissues [21]. A few GLP-1RAs, such as liraglutide and semaglutide, have been shown to effectively improve cardiovascular outcomes in patients with T2DM in the Liraglutide Effect and Action in Diabetes: Evaluation of Cardiovascular Outcome Results (LEADER) trial and the Trial to Evaluate Cardiovascular and Other Long-term Outcomes with Semaglutide in Subjects with Type 2 Diabetes (SUSTAIN-6) trial, respectively [22,23]. Previous studies reported that dipeptidyl peptidase-4 (DPP-4) rapidly metabolizes GLP-1 into GLP-1 (9-36) amide, resulting in the loss of its insulinotropic activity [24,25]. However, recent studies reported that GLP-1 (9-36) amide has a GLP-1R-independent cardioprotective action [26,27].

In the present study, we investigated the protective effects and regulatory mechanism of GLP-1RAs on Ang II-induced VSMC proliferation and migration and Pi-induced VSMC calcification.

METHODS

Cell culture

The rat aortic A-10 VSMC line was purchased from the American Type Culture Collection (ATCC, Manassas, VA, USA) and was cultured in Dulbecco's modified Eagle's medium (DMEM) high glucose (25 mmol/L, Gibco, Grand Island, NY, USA) supplemented with 10% fetal bovine serum (FBS, Hyclone, Logan, UT, USA) and 1% penicillin/streptomycin (Gibco) in an incubator at 37 \degree C with a humidified atmosphere of 5% $CO₂$ in the air. To examine the protective effects of GLP-1RAs on proliferation and migration of VSMCs induced by Ang II (Sigma-Aldrich, St. Louis, MO, USA), the cells were pretreated with either 100 nM exendin-4 (Sigma-Aldrich), liraglutide, or dulaglutide (MedChemExpress, Monmouth Junction, NJ, USA) 1 hour before Ang II treatment. During treatment with Ang II and GLP-1RAs, the cells were incubated in DMEM supplemented with 0.5% FBS (Hyclone). To examine the effects of GLP-1RAs on vascular calcification, cells exposed to 4 mM Pi (Sigma-Aldrich) were treated with 100 nM exendin-4, liraglutide, or dulaglutide for 7 days. The media was changed every 2 to 3 days. Lipopolysaccaharide (Merck Millipore, Burlington,

MA, USA) and thapsigargin (Sigma-Aldrich) were treated to activate the mitogen-activated protein kinase (MAPK) pathway and endoplasmic reticulum (ER) stress, respectively.

Cell proliferation assay

For analysis of VSMC proliferation, cell viability was determined using an MTT cell proliferation assay kit (Invitrogen, Carlsbad, CA, USA). Cells were seeded in 96 well plates and incubated until 80% confluent. After serum starvation for 6 hours, cells were treated with various concentrations of chemicals for 24 hours. The cell culture medium was removed and replaced with 100 µL fresh culture medium, and 10 µL of the 12 mM MTT stock solution was added. The plate was incubated at 37°C for 4 hours, following which 100 µL of sodium dodecyl sulfate in 0.01 N HCl was added, and the absorbance was read at 450 nm using a microplate reader (TECAN, Grödig, Austria).

Transwell migration assay

VSMC migration was determined using the transwell migration assay as previously described [28]. Briefly, the confluent monolayers of VSMCs in 6-well plates were treated with of 1 µM Ang II in the absence or presence of GLP-1RAs at 37°C for 16 hours. The cells were then trypsinized with 0.25% (v/v) trypsin, resuspended in serum-free DMEM, and seeded in the upper chamber of each transwell. In the lower chamber of each transwell, DMEM supplemented with 10% FBS was added as a chemoattractant. After incubation for 24 hours, the upper chamber was fixed with 4% (w/v) formaldehyde for 20 minutes at room temperature, washed with phosphate-buffered saline (PBS), and stained with crystal violet (Sigma-Aldrich) for 15 minutes. After washing with distilled water, the non-migrated cells from the upper surface of the transwell membrane were removed using a cotton swab, and images were captured by microscopy at ×100 magnification (Olympus IX71, Olympus, Tokyo, Japan).

Scratch wound healing assay

In addition to the transwell migration assay, VSMC migration was also determined using the scratch wound healing assay. VSMCs were seeded in 6-well plates and when the cells reached 80% to 90% confluence, they were scratched using 200 µL yellow tips in the center of each well. After washing with PBS, the cells were incubated with the chemicals indicated in each experiment. Images were captured at 0 hour and at the

time point indicated in the figures $(\times 100$ magnification). VSMC migration was quantified by measuring the distance of the scratch wound at both time points using ImageJ and expressed as follows: % gap distance=[(distance at 0 hour time points–distance at the indicated time points)/distance at 0 hour time points \times 100.

Immunofluorescence staining

VSMCs were cultured on coverslips, fixed with 4% formaldehyde for 5 minutes, permeabilized with pre-chilled 0.5% Triton X-100 for 5 minutes at –20°C, and incubated with a normal goat serum blocking solution for 1 hour at room temperature. The cells were incubated overnight with the primary anti-proliferating cell nuclear antigen (*Pcna*) antibody at 4°C and were then labeled with a tetramethylrhodamine isothiocyanateconjugated secondary antibody for 1 hour at room temperature. Next, the cells were mounted using a mounting medium with 4´,6-diamidino-2-phenylindole (DAPI; ab104139, Abcam, Cambridge, UK), and images were obtained using a fluorescence microscope (BX51, Olympus).

Quantitative real-time polymerase chain reaction

The total RNA was extracted from VSMCs using the TRIzol reagent (Invitrogen) and cDNA was synthesized via reverse-transcription using the High-Capacity RNA-to-cDNA Kit (Applied Biosystems, Foster City, CA, USA), according to the manufacturer's instructions. Quantitative real-time polymerase chain reaction (PCR) for target gene expression was performed with LightCycler 480 SYBR Green (Roche, Lewis, UK). The primer pairs used for PCR were purchased from Bioneer (Daejeon, Korea). The primer sequences are presented in Supplementary Table 1. The expression levels of the target genes were normalized to the internal control gene (glyceraldehyde-3-phosphate dehydrogenase [*Gapdh*]) and calculated using the 2−ΔΔCt method.

Calcium deposition assay

To determine the calcium content, cells were incubated with 0.5 N HCl for 24 hours at 4°C. The decalcified solution was measured using the QuantiChrom Calcium Assay Kit (BioAssay Systems, Hayward, CA, USA) and the calcium content was normalized to the total protein concentration. To determine the calcium deposition in the extracellular matrix, the cells were washed with PBS, fixed with 10% formalin for 10 minutes at room temperature, and stained with 0.5% alizarin red S so-

lution for 30 minutes at 37°C. The cells were then washed twice with PBS and photographed using a microscope (Olympus).

Western blotting

The cells were lysed with radioimmunoprecipitation assay (RIPA) buffer (Cell Signaling Technology, Danvers, MA, USA) containing the Halt Protease and Phosphatase Inhibitor Cocktail (100×) (Thermo Fisher Scientific, Rockford, IL, USA), and the concentration of protein was calculated using Bradford protein analysis (Bio-Rad, Hercules, CA, USA). For Western blotting, protein samples (20 µg) were dissolved in 4× lithium dodecyl sulfate sample buffer and $10\times$ reducing sample agent (Invitrogen), heated at 95°C for 10 minutes, and loaded on a 4% to 12% Bis-Tris NuPAGE gel (Thermo Fisher Scientific). The separated proteins were transferred to a polyvinylidene difluoride (PVDF) membrane using the iBlot2 PVDF stack (Invitrogen), and the membranes were blocked with 5% bovine serum albumin in tris-buffered saline with Tween-20 (TBST) for 1 hour at room temperature, following which they were incubated at 4°C overnight with the following specific primary antibodies (Supplementary Table 2). After washing with TBST, the membranes were incubated with horseradish peroxidase-conjugated secondary antibodies for 1 hour at room temperature. Protein bands were visualized by enhanced chemiluminescence reagent (DAWINBio, Hanam, Korea).

Transient siRNA transfection

The A-10 cells were transfected with GLP-1R or activating transcription factor 4 (Atf4) siRNA (Bioneer) using Lipofectamine RNAi MAX transfection reagent (Invitrogen), according to the manufacturer's instructions. Scrambled siRNA was used as a negative control for transfection. After 24 hours of GLP-1R transfection, the cells were treated with 1 μM Ang II in the presence or absence of various concentration of GLP-1 (9-36) amide (MedChemExpress) or either 100 nM exendin-4, liraglutide, or dulaglutide for 24 hours and harvested for further analysis. After 24 hours of Atf4 siRNA transfection, the cells were treated with 4 mM Pi in the presence or absence of 100 nM exendin-4, liraglutide, or dulaglutide and harvested for further analysis.

Statistical analysis

All data were collected in triplicate and are expressed as mean ± standard error values. The statistical analysis was performed using SPSS version 12.0 software (SPSS Inc., Chicago, IL,

USA). The data were analyzed using one-way analysis of variance, followed by *post hoc* Bonferroni multiple range tests to calculate significant differences between the mean values obtained from the different experimental groups. A *P* value of <0.05 was considered statistically significant.

RESULTS

Ang II induces migration and proliferation in VSMCs

Excessive increase in VSMC proliferation and migration are important hallmarks of atherosclerosis, and Ang II, as well as some types of cytokines and growth factors, stimulate proliferation and migration in VSMCs [9]. Exposure of the A-10 cells to different concentrations of Ang II produced an increase in migration and proliferation of VSMCs, which were observed using the scratch wound healing assay and MTT, respectively (Supplementary Fig. 1A and B). In addition, the expression of Ang II receptors, AT1 and AT2, was increased by Ang II in a dose-dependent manner (Supplementary Fig. 1C). Thus, these results indicate that Ang II induces VSMC proliferation and migration via AT1 and AT2, and 1 µM Ang II should be used as an appropriate concentration to induce VSMC proliferation and migration in further studies.

GLP-1RAs inhibit Ang II-induced migration and proliferation of VSMCs

To examine the effects of GLP-1RAs on Ang II-induced VSMC migration and proliferation, A-10 cells treated with Ang II were exposed to exendin-4, liraglutide, and dulaglutide. GLP-1RAs significantly decreased Ang II-induced VSMC migration, which was demonstrated by the scratch wound healing and transwell migration assays (Fig. 1A and B). In addition, GLP-1RAs inhibited the proliferation of Ang II-treated cells (Fig. 1C). These results indicate that GLP-1RAs reverse the Ang IIinduced increase in migration and proliferation of VSMCs.

GLP-1RAs decrease Erk and JNK activation and proliferation marker expression in Ang II-treated VSMCs

We examined whether exendin-4, liraglutide, and dulaglutide regulate the expression of extracellular signal-regulated kinase (Erk), c-JUN N-terminal kinase (JNK), and phosphatidylinositol 3-kinase (Pi3k)/protein kinase B (Akt) signaling pathways in Ang II-treated cells. Ang II increased the protein expression of phospho-Erk (p-Erk), p-JNK, and p-Pi3k in a dose-dependent manner (Fig. 2A). Compared with controls, gene expres-

Fig. 1. Exendin-4, liraglutide, and dulaglutide inhibit the migration and proliferation of vascular smooth muscle cells (VSMCs) treated with angiotensin II (Ang II). A-10 cells are treated with 1 μM Ang II, followed by treatment with or without 100 nM exendin-4 (Ex-4), liraglutide (Lira), and dulaglutide (Dula) for 48 hours. (A, B) VSMC migration is determined using scratch wound healing assay and transwell migration assay, and (C) VSMC proliferation is determined using MTT assay. ^aP<0.05 and ^bP<0.01 when compared with the control cells, *P*<0.05 and ^dP<0.01 when compared with the Ang II-treated cells.

sion of marker of proliferation Ki-67 (*Mki-67*), *Pcna*, and cyclin D1 (*Ccnd1*) was increased the most in cells treated with 0.1 µM Ang II (Fig. 2B). Treatment with exendin-4, liraglutide, and dulaglutide decreased the expression of p-Ekr and p-JNK proteins (Fig. 2C) and *Pcna* gene (Fig. 2D) relative to control cells treated with Ang II alone. Also, GLP-1RAs decreased the expression of nuclear factor-κB (NF-κB), which is a downstream factor of Erk and JNK signaling pathways (Supplementary Fig. 2). *Mki-67* expression was significantly decreased only in the cells treated with liraglutide, and *Ccnd1* expression was decreased in the cells treated with exendin-4 and liraglutide compared with *Ccnd1* expression in cells treated with Ang II alone. No significant difference was observed in the expression of p-Pi3k protein between cells treated with Ang II alone and those treated with exendin-4, liraglutide, or dulaglutide. Furthermore, immunofluorescence staining of Pcna revealed that the number of positive cells was lower among cells treated with exendin-4, liraglutide, or dulaglutide than among cells treated with Ang II alone (Supplementary Fig. 3).

GLP-1RAs decrease proliferation marker expression by inhibiting Erk and JNK in Ang II-treated VSMCs, and their effects are mediated by GLP-1R

To determine whether the GLP-1RAs inhibits VSMC prolifera-

Fig. 2. Exendin-4, liraglutide, and dulaglutide inhibit extracellular signal-regulated kinase (Erk) and c-JUN N-terminal kinase (JNK) signaling pathways and the expression of proliferation marker genes in vascular smooth muscle cells (VSMCs) treated with angiotensin II (Ang II). (A, B) A-10 cells are treated with various concentrations of Ang II for 24 hours. (C, D) A-10 cells are treated with 1 μM Ang II, followed by treatment with or without 100 nM exendin-4 (Ex-4), liraglutide (Lira), and dulaglutide (Dula) for 24 hours. p-Erk, p-JNK, and phospho-phosphatidylinositol 3-kinase (p-Pi3k) levels are analyzed using Western blotting. The mRNA expression levels of the genes encoding marker of proliferation Ki-67 (*Mki-67*), proliferating cell nuclear antigen (*Pcna*), and cyclin D1 (*Ccnd1*) are analyzed with quantitative real-time polymerase chain reaction and normalized to that of the glyceraldehyde-3-phosphate dehydrogenase (*Gapdh*) gene. ^aP<0.05 and ^bP<0.01 when compared with the control (CON) cells, ^cP<0.05 and ^dP<0.01 when compared with the Ang U-treated cells. ^dP<0.01 when compared with the Ang II-treated cells.

Fig. 3. Inhibitory effects of exendin-4 (Ex-4), liraglutide (Lira), and dulaglutide (Dula) on the expression of extracellular signal-regulated kinase (Erk) and c-JUN N-terminal kinase (JNK) are mediated by glucagon-like peptide-1 receptor (GLP-1R). A-10 cells pre-exposed to (A) 50 μM Erk inhibitor (PD98059) or (B) 50 μM JNK inhibitor (SP600125) for 1 hour are treated with 1 μM angiotensin II (Ang II), followed by treatment with or without Ex-4 (100 nM), Lira (100 nM), and Dula (100 nM) for 24 hours. (C) A-10 cells, transfected with 50 nM GLP-1R siRNA or scrambled (Scr) siRNA for 24 hours, are treated with Ang II, followed by treatment with or without Ex-4, Lira, and Dula for 24 hours. Expression levels of phosphor-Erk (p-Erk), p-JNK, proliferating cell nuclear antigen (Pcna), and cyclin D1 are analyzed using Western blotting, and glyceraldehyde-3-phosphate dehydrogenase (Gapdh) is used as the loading control. ^aP<0.05 and ^bP<0.01 when compared with the control cells, ^cP<0.05 and ^dP<0.01 when compared with the Ang II-treated cells.

tion via Erk and JNK signaling pathways, cells were treated with PD98059 (Erk inhibitor) or SP600125 (JNK inhibitor). Inhibition of Ekr by PD98059 treatment decreased the expression of p-Erk, Pcna, and Ccnd1 proteins (Fig. 3A), while inhibition of JNK by SP600125 treatment decreased the expression of p-JNK, Pcna, and Ccnd1 proteins (Fig. 3B). Consistently, inhibition of Erk and JNK by inhibitor treatment significantly reduced cell proliferation compared with inhibitor-untreated groups (Supplementary Fig. 4). While lipopolysaccharide-induced Erk and JNK activation reversed the reduction by GLP-1RAs in VSMC migration (Supplementary Fig. 5). Next, we examined whether the inhibition of Erk and JNK signaling pathway by exendin-4, liraglutide, and dulaglutide treatment in Ang II-treated VSMCs was mediated through a GLP-1R-dependent pathway. Cells were transfected with GLP-1R siRNA, and we observed that GLP-1R inhibition by siRNA reversed the reduction of p-Erk and p-JNK expression by GLP-1RAs. (Fig. 3C). These data show that inhibitory effects by exendin-4, liraglutide, and dulaglutide in proliferation and migration of VSMCs are mediated through a GLP-1R-dependent pathway.

GLP-1 (9-36) amide decreases proliferation and migration in

Ang II-treated VSMCs and increases the expression of Cd36 To demonstrate the involvement of the GLP-1R-independent pathway in the cardioprotective effect of GLP-1, Ang II-treated VSMCs were exposed to various concentrations of GLP-1 (9- 36) amide, which is a metabolite of intact GLP-1 (7-36). GLP-1 (9-36) amide increased the protein expression of Cd36, a multifunctional membrane signaling receptor, and decreased the protein expression of p-Erk, p-JNK, Pcna, and Ccnd1 (Fig. 4A). In addition, GLP-1 (9-36) amide inhibited the migration of Ang II-induced VSMCs (Fig. 4B and C). Interestingly, the anti-proliferative effect in cells treated with 100 nM GLP-1(9- 36) was also observed in cells transfected with GLP-1R siRNA (Fig. 4D). These findings indicate that GLP-1 (9-36) amide inhibits the aberrant migration and proliferation of VSMCs through a GLP-1R independent pathway.

GLP-1RAs decrease Pi-induced calcium deposition by inhibiting Atf4 in VSMCs

We examined the effect of exendin-4, liraglutide, and dulaglutide on Pi-induced vascular calcification in VSMCs. GLP-1RAs diminished calcium deposition compared with that in the cells treated by Pi alone (Fig. 5A and B). The gene expressions of ER stress markers 78 kDa glucose-regulated protein (*Grp78*), protein kinase RNA-like endoplasmic reticulum kinase (*Perk*), inositol-requiring protein 1 (*Ire1*), activating transcription factor 6 (*Atf6*), Atf4, and C/EBP homologous protein (*CHOP*) and the protein expression of Atf4 transcription factor and CHOP, which are downstream factors of Perk, were increased in the Pi-treated cells compared with that in the control group, while it was reversed in cells treated with GLP-1RAs (Fig. 5C and D). In addition, the inhibition of Atf4 by siRNA dramatically decreased the expression of bone morphogenic protein 2 (Bmp2) and runt-related transcription factor-2 (Runx2) proteins, which are markers of osteoblastic differentiation in VSMCs (Fig. 5E), and diminished calcium deposition in cells treated Pi alone and Pi+exendin-4 (Fig. 5F). While ER stress inducer thapsigargin-induced Atf4 activation reversed the reduced calcium deposition by GLP-1RAs (Supplementary Fig. 6). These data indicate that GLP-1RAs have anti-calcification effects in Pi-treated VSMCs, and beneficial effects of GLP-1RAs are mediated through inhibition of osteoblastic differentiation of VSMCs via Atf4 inhibition.

DISCUSSION

In this study, we determined that GLP-1RAs have protective effects against the progression of coronary atherosclerosis via both GLP-1R-dependent and GLP-1R-independent pathways. GLP-1RA also has an anti-calcification effect by inhibition of Atf4. The GLP-1RAs exendin-4, liraglutide, and dulaglutide inhibited the aberrant increase in migration and proliferation of Ang II-treated VSMCs and decreased the expression of proliferation markers Pcna and Ccnd1 by inhibiting the Erk and JNK signaling pathways, which are involved in processes of cell growth and survival. However, GLP-1R inhibition by siRNA reversed the reduction of p-Erk and p-JNK expression caused by GLP-1RAs. Moreover, GLP-1 (9-36) amide showed similar improvement effects as GLP-1RAs on the proliferation and migration of VSMCs and the anti-proliferative effect of GLP-1 (9-36) amide is mediated by a GLP-1R-independent pathway. Furthermore, in rat VSMCs treated with a high concentration of Pi, exendin-4, liraglutide, and dulaglutide inhibited calcium deposition and decreased the expression of osteoblastic differentiation markers Bmp2 and Runx2 by inhibiting Atf4 (Fig. 6).

The extraglycemic effect of the anti-diabetic medication is becoming increasingly important for the prevention of diabetes complications. Recently, a number of studies reported the results of CVD trials investigating the effect of GLP-1RAs in-

Fig. 4. Glucagon-like peptide-1 (GLP-1) (9-36) amide decreases the proliferation and migration of vascular smooth muscle cells (VSMCs) treated with angiotensin II (Ang II) by increasing Cd36 expression. A-10 cells are treated with 1 μM Ang II, followed by treatment with various concentrations of GLP-1 (9-36) amide (1 to 100 nM) for 24 or 48 hours. (A) Expression levels of phosphoextracellular signal-regulated kinase (p-Erk), phospho-c-JUN N-terminal kinase (p-JNK), Cd36, proliferating cell nuclear antigen (Pcna), and cyclin D1 are analyzed using Western blotting, and glyceraldehyde-3-phosphate dehydrogenase (Gapdh) is used as the loading control (CON). (B, C) VSMC migration is determined using scratch wound healing assay and quantified. (D) A-10 cells transfected with 50 nM GLP-1 receptor (GLP-1R) siRNA or scramble (Scr) siRNA are treated with 1 μM Ang II, followed by treatment with various concentrations of GLP-1 (9-36) amide (1 to 100 nM) for 24 hours. VSMC proliferation is determined using MTT assay. ^aP<0.05 and ^bP<0.01 when compared with the CON cells, ^cP<0.05 and ^dP<0.01 when compared with the Ang II-treated cells.

Fig. 6. Schematic diagram illustrating a possible mechanism of the protective effect of glucagon-like peptide-1 receptor agonists (GLP-1RAs) on cardiovascular disease. Ang II, angiotensin II; Pi, inorganic phosphate; AT1, angiotensin II receptor type 1; AT2, angiotensin II receptor type 2; Erk, extracellular signal-regulated kinase; JNK, c-JUN N-terminal kinase; VSMC, vascular smooth muscle cell; ER, endoplasmic reticulum; Atf4, activating transcription factor 4; Bmp2, bone morphogenic protein 2; Runx2, runtrelated transcription factor-2.

cluding lixisenatide, liraglutide, semaglutide, exenatide, albiglutide, dulaglutide, and oral semaglutide in patients with T2DM, and established CVD risk factors [29,30]. A metaanalysis pooling the results of these randomized controlled trials showed that GLP-1RA treatment significantly reduced the risk of major adverse cardiac events by 12%, death due to CVD by 11%, stroke by 16%, myocardial infarction by 9%, and allcause death by 12% compared with a placebo group [31].

GLP-1 is a gut hormone that has a beneficial effect on nonalcoholic fatty liver disease and CVD in patients with T2DM, through GLP-1R [32]. GLP-1 (9-36) amide, which is a metabolite of GLP-1 produced by DPP-4 cleavage, is metabolically in-

active [33]. However, some previous studies reported that protective functions of GLP-1, exendin-4, and GLP-1 (9-36) amide against ischemia-reperfusion injury in hearts isolated from mice and rats [27,34]. The insulinomimetic effects of GLP-1 derived peptides, including GLP-1 (9-36) amide and GLP-1 (28-36) amide, modulated hepatic glucose production, antioxidant cardioprotective action, oxidative stress in vasculature tissue [35], and improved β-cell injury in the streptozotocindiabetic mice [36]. In this study, we observed that exendin-4, liraglutide, and dulaglutide inhibited the proliferation and migration of Ang II-treated VSMCs and reduced the expression of proliferation markers, *Pcna* and *Ccnd1* by inhibiting Erk

and JNK signaling via the GLP-1R-dependent pathway. In addition, GLP-1 (9-36) amide caused a dose-dependent decrease in VSMC migration and proliferation. Tomas and Habener [35] reported that GLP-1 (9-36) amide is transported in the cell through binding to CD36/fatty acid translocase, which is a receptor involved in the transport of peptides and oxidized LDLs. Our results show that GLP-1 (9-36) amide increased the expression of Cd36 in Ang II-treated VSMCs in a dose-dependent manner. These results indicate that GLP-1RAs have direct protective effects against vascular disease through GLP-1R-dependent and GLP-1R-independent pathways.

Vascular calcification is a marker of CVD. In particular, calcification in the medial layer of the artery wall, which is composed of VSMCs, is closely related to diabetes [37]. VSMCs treated with a high concentration of Pi results in vascular calcification through various mechanisms including transdifferentiation of VSMCs into osteoblast-like cells, apoptosis, mineral vesicle release, ER stress, and oxidative stress [38,39]. We observed that exendin-4, liraglutide, and dulaglutide inhibited calcium deposition and reduced the gene expression of ER stress markers in Pi-treated VSMCs. Furthermore, we observed that Atf4 inhibition reduced the expression of osteoblastic differentiation markers Bmp2 and Runx2 and calcium deposition in Pi-treated VSMCs. These results indicate that GLP-1RAs have protective effects against vascular calcification in Pi-treated VSMCs, and these effects could be mediated by inhibition of VSMCs transdifferentiation into osteoblast-like cells via amelioration of ER stress.

In conclusion, the present study showed that GLP-1RAs have a direct protective effect against vascular disease, and their anti-atherosclerotic effects might be mediated by both GLP-1R-dependent and GLP-1R-independent pathways. The GLP-1RAs treatment in Ang II-treated VSMCs inhibited migration and proliferation of VSMCs by inhibiting the Erk and JNK signaling pathways. Moreover, GLP-1 (9-36) amide also showed an inhibitory effect on VSMC migration and proliferation. We also found that GLP-1RAs had anti-calcification effects via inhibition of osteoblastic differentiation in Pi-treated VSMCs, which was mediated by Atf4 inhibition. Thus, treatment with GLP-1RAs may be a useful approach in the treatment of atherosclerosis and vascular calcification, which are the causes and risk factors for CVD. Further studies are required to clarify the role and underlying regulatory mechanism of Cd36 on the migration and proliferation of VSMCs by GLP-1 (9-36) amide. In addition, further studies are required to elucidate which major receptors mediate the beneficial effects of GLP-1 (9-36) amide in the coronary arteries, and *in vivo* experiments are needed to solidify our findings.

Supplementary Table 1. List of rat primer for quantitative real-time polymerase chain reaction

AT1, angiotensin II receptor type 1; *AT2*, angiotensin II receptor type 2; *Mki-67*, marker of proliferation Ki-67; *Pcna*, proliferating cell nuclear antigen; *Ccnd1*, cyclin D1; *Nfkb1*, nuclear factor kappa B subunit 1; *Grp78*, 78 kDa glucose-regulated protein; *Perk*, protein kinase RNA-like endoplasmic reticulum kinase; *Ire1*, inositol-requiring protein 1; *Atf6*, activating transcription factor 6; *Atf4*, activating transcription factor 4; *CHOP*, C/EBP homologous protein; *Gapdh*, gluceradehyde-3-phosphate dehydrogenase.

dmj

Supplementary Table 2. List of primary antibodies used for Western blotting

Erk, extracellular signal-regulated kinase; JNK, c-JUN N-terminal kinase; Pi3k, phosphatidylinositol 3-kinase; Nf-κB, nuclear factor-κB; Pcna, proliferating cell nuclear antigen; Atf4, activating transcription factor 4; CHOP, C/EBP homologous protein; Bmp2, bone morphogenic protein 2; Runx2, runt-related transcription factor-2; Gapdh, gluceradehyde-3-phosphate dehydrogenase.

Supplementary Fig. 1. Angiotensin II (Ang II) induces migration and proliferation of vascular smooth muscle cells (VSMCs) via angiotensin II receptor type 1 (AT1) and AT2 receptors. A-10 cells are treated with various concentrations of Ang II for 24 hours. VSMC migration and proliferation are determined using (A) scratch wound healing assay and (B) MTT assay, respectively. (C) mRNA expression levels of the genes encoding *AT1* and *AT2* are analyzed with quantitative real-time polymerase chain reaction and normalized to that of the gluceradehyde-3-phosphate dehydrogenase (*Gapdh*) gene. ^aP<0.05 and ^bP<0.01 when compared with the control cells.

Supplementary Fig. 2. Exendin-4 (Ex-4), liraglutide (Lira), and dulaglutide (Dula) decrease nuclear factor-κB (Nf-κB) expression in vascular smooth muscle cells treated with angiotensin II (Ang II). A-10 cells are treated with 1 μM Ang II, followed by treatment with or without 100 nM Ex-4, Lira, and Dula for 24 hours. The protein and gene expression of Nf-κB are analyzed using Western blotting and quantitative real-time polymerase chain reaction, respectively. Gapdh, gluceradehyde-3-phosphate dehydrogenase; CON, control. ^aP<0.05 and ^bP<0.01 when compared with the control cells, ^cP<0.05 and ^dP<0.01 when compared with the Ang II-treated cells.

Supplementary Fig. 3. Detection of proliferating cell nuclear antigen (Pcna) by immunofluorescence. Cells are counterstained and quantified with Pcna (red) and 4´,6-diamidino-2-phenylindole (DAPI; nuclear, blue). Scale bar 100 μm (×100 magnification). CON, control; Ex-4, exendin-4; Lira, liraglutide; Dula, dulaglutide. ^aP<0.01 when compared with the control cells, ^bP<0.05 and ^cP<0.01 when compared with the angiotensin II (Ang II)-treated cells.

Supplementary Fig. 4. Extracellular signal-regulated kinase (Erk) and c-JUN N-terminal kinase (JNK) inhibitors inhibit the proliferation of vascular smooth muscle cells (VSMCs). A-10 cells pre-exposed to 50 μM Erk inhibitor (PD98059) or 50 μM JNK inhibitor (SP600125) for 1 hour are treated with 1 μM angiotensin II (Ang II), followed by treatment with or without exendin-4 (Ex-4; 100 nM), liraglutide (Lira; 100 nM), and dulaglutide (Dula; 100 nM) for 24 hours. VSMC proliferation is determined using MTT assay. CON, control. ^aP<0.01 when compared with the control cells, ^bP<0.01 when compared with the Ang II-treated cells, ^cP<0.01 when compared with each inhibitor-untreated groups.

Supplementary Fig. 5. Lipopolysaccharide (LPS)-induced extracellular signal-regulated kinase (Erk) and c-JUN N-terminal kinase (JNK) activation reverse glucagon-like peptide-1 receptor agonists-induced inhibition in vascular smooth muscle cell (VSMC) migration. A-10 cells pre-exposed to 0.1 μg/mL lipopolysaccharide for 1 hour are treated with 1 μM angiotensin II (Ang II), followed by treatment with or without 100 nM exendin-4 (Ex-4), liraglutide (Lira), and dulaglutide (Dula) for 24 hours. (A) The protein expression of p-Erk and p-JNK are analyzed using Western blotting and (B, C) VSMC migration is determined using scratch wound healing assay. CON, control. ^aP<0.01 when compared with the control cells, ^bP<0.01 when compared with the Ang II-treated cells, <P<0.05 when compared with each LPS-untreated groups.

Supplementary Fig. 6. Thapsigargin-induced activating transcription factor 4 (ATF4) activation reverses the anti-calcification effect by glucagon-like peptide-1 receptor agonists. A-10 cells pre-exposed to 0.1 μM thapsigargin for 24 hours are treated with 4 mM inorganic phosphate (Pi), followed by treatment with or without 100 nM exendin-4 (Ex-4), liraglutide (Lira), and dulagutide (Dula) for 7 days. (A) The protein expression of Atf4, bone morphogenic protein 2 (Bmp2), and runt-related transcription factor-2 (Runx2) are analyzed using Western blotting and (B) levels of calcium deposition are assessed by calcium levels. ^aP<0.01 when compared with the control cells, ^bP<0.05 and ^cP<0.01 when compared with the Pi-treated cells, ^dP<0.05 when compared with each thapsigargin-untreated groups.
