Abstract

Background The availability of robust biomarkers of endothelial activation might enhance the identification of subclinical atherosclerosis in rheumatoid arthritis (RA). We investigated this issue by conducting a systematic review and meta-analysis of cell adhesion molecules in RA patients.

Methods We searched electronic databases from inception to 31 July 2023 for case–control studies assessing the circulating concentrations of immunoglobulin-like adhesion molecules (vascular cell, VCAM-1, intercellular, ICAM-1, and platelet endothelial cell, PECAM-1, adhesion molecule-1) and selectins (E, L, and P selectin) in RA patients and healthy controls. Risk of bias and certainty of evidence were assessed using the JBI checklist and GRADE, respectively.

Results In 39 studies, compared to controls, RA patients had significantly higher concentrations of ICAM-1 (standard mean difference, SMD = 0.81, 95% CI 0.62–1.00, $p < 0.001$; $I^2 = 83.0%$, $p < 0.001$), VCAM-1 (SMD = 1.17, 95% CI 0.73–1.61, $p < 0.001$; $I^2 = 95.8%$, $p < 0.001$), PECAM-1 (SMD = 0.82, 95% CI 0.57–1.08, $p < 0.001$; $I^2 = 0.0%$, $p = 0.90$), E-selectin (SMD = 0.64, 95% CI 0.42–0.86, $p < 0.001$; $I^2 = 75.0%$, $p < 0.001$), and P-selectin (SMD = 1.06, 95% CI 0.50–1.60, $p < 0.001$; $I^2 = 84.8%$, $p < 0.001$), but not L-selectin. In meta-regression and subgroup analysis, significant associations were observed between the effect size and use of glucocorticoids (ICAM-1), erythrocyte sedimentation rate (VCAM-1), study continent (VCAM-1, E-selectin, and P-selectin), and matrix assessed (P-selectin).

Conclusions The results of our study support a significant role of cell adhesion molecules in mediating the interplay between RA and atherosclerosis. Further studies are warranted to determine whether the routine use of these biomarkers can facilitate the detection and management of early atherosclerosis in this patient group.

Introduction

Despite significant advances, particularly over the last two decades, in diagnosis, treatment, and follow-up, patients with rheumatoid arthritis (RA) continue to experience poor quality of life and inadequate social engagement [1–5]. There is also increasing evidence that the coexistence of RA and specific comorbidities exerts an additional public health and financial burden on patients and the healthcare workforce [6–8]. In particular, the link between RA and atherosclerosis is well established given the high prevalence of cardiovascular risk factors [9–14], the high incidence of myocardial infarction and stroke [15–19], and the recognition that cardiovascular disease represents the leading cause of mortality in RA patients [20, 21]. To

further corroborate the link between RA and atherosclerosis, a considerable body of research has demonstrated significant alterations in the endothelial synthesis of the critical endogenous messenger, nitric oxide [22, 23], impaired endothelial and flow-mediated vasodilatation [24–27], intima–media thickening [28], arterial stiffening [29], and increased risk of hypertension in RA patients [30]. These abnormalities are often observed in the early phases of atherosclerosis, reflecting a state of endothelial activation and early damage of the tunica intima of the arterial wall [31, 32], and therefore their detection might instigate timely prevention strategies [33–35].

At a cellular and molecular level, the early stages of atherosclerosis are characterized by the adhesion of leukocytes and lymphocytes to the endothelium. This, in turn, facilitates the migration of these cells to the tunica intima [36, 37]. The process of cellular adhesion to the endothelium is mediated by a number of molecules, including the immunoglobulin-like vascular cell adhesion molecule-1 (VCAM-1), the intercellular vascular adhesion molecule-1 (ICAM-1), and the platelet endothelial cell adhesion molecule-1 (PECAM-1) [38–41]. VCAM-1 is primarily expressed in endothelial cells and macrophages and its binding to integrin $\alpha_4\beta_1$ mediates its biological effects [42, 43]. ICAM-1 is upregulated in the presence of excess inflammation and binds to the leukocyte specific β_2 integrins [44, 45]. PECAM-1 is expressed in leukocytes, platelets, and endothelial cells, and favors the migration of leukocytes through the translocation of the integrin $\alpha_6\beta_1$ [46]. The immunoglobulin-like vascular cell adhesion molecules can be measured in plasma or serum [41, 47, 48], and their concentrations have been shown to be positively associated with cardiovascular risk [49–53]. Another group of molecules facilitating cell adhesion to the endothelium includes the selectins, specifically P-selectin, expressed in platelets and endothelial cells, L-selectin, expressed in leukocytes, and E-selectin, expressed in endothelial cells [54–56]. Selectins mediate the rolling of monocytes, neutrophils, and lymphocytes [57, 58], can also be measured in plasma or serum, and have been shown to play an important pathophysiological role in RA, angiogenesis, and atherosclerosis [59–68].

Therefore, given the robust association between RA and atherosclerosis and the potential utility of cell adhesion molecules in the identification of early, subclinical atherosclerosis, we conducted a systematic review and meta-analysis of the circulating concentrations of VCAM-1, ICAM-1, PECAM-1, P-selectin, L-selectin, and E-selectin in RA patients and healthy controls. We hypothesized that RA is associated with a significant upregulation of cell adhesion molecules, suggesting endothelial activation and dysfunction in this patient group.

Methods

Search strategy and study selection

We searched PubMed, Scopus, and Web of Science from inception to 31 July 2023 for relevant articles using the following terms and their combinations: “rheumatoid arthritis” AND “soluble cell adhesion molecules” OR “intercellular adhesion molecule-1” OR “ICAM-1” OR “sICAM-1” OR “ICAM” OR “vascular cell adhesion molecule-1” OR “VCAM-1” OR “sVCAM-1” OR “VCAM” OR “platelet endothelial cell adhesion molecule-1” OR “PECAM-1” OR “sPECAM-1” OR “PECAM” OR “selectin” or “P-selectin” OR “sP-selectin” OR “L-selectin” OR “sL-selectin” OR “E-selectin” OR “sE-selectin”. Two investigators independently screened the abstracts and, if relevant, the full articles, including their references, according to the following criteria: (a) assessment of soluble ICAM-1, VCAM-1, PECAM-1, E-selectin, L-selectin, and P-selectin in plasma or serum, (b) comparison of RA patients and healthy controls in a case–control study, (c) age of participants ≥ 18 years, (d) publications in English language, and (e) full-text article available.

The following information was independently extracted from selected manuscripts: year of publication, first author, study country and continent, number of RA patients and controls, age, sex distribution, C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), RA duration, disease activity score-28 (DAS-28), matrix used for assessment (serum or plasma), method used to measure adhesion molecules, and use of methotrexate, glucocorticoids, and disease-modifying antirheumatic drugs (DMARDs).

The risk of bias was assessed using the Joanna Briggs Institute Critical Appraisal Checklist for analytical studies and the certainty of evidence using the Grades of Recommendation, Assessment, Development, and Evaluation (GRADE) Working Group system [69, 70]. We complied with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) 2020 statement (Supplementary Tables S1 and S2) [71]. The protocol was registered in the International Prospective Register of Systematic Reviews (PROSPERO Registration No. CRD42023466662).

Statistical analysis

We calculated standardized mean differences (SMDs) and 95% confidence intervals (CIs) to generate forest plots of continuous data and investigate differences in the concentrations of cell adhesion molecules between RA patients and healthy controls (a p value < 0.05 was considered statistically significant) [72–74]. The heterogeneity of

SMD across studies was evaluated using the Q-statistic (a p value $p < 0.10$ was considered statistically significant). Heterogeneity was considered low when $I^2 \leq 25\%$, moderate when $25\% < I^2 < 75\%$, and high when $I^2 \geq 75\%$. A random-effects model based on the inverse-variance method was used in case of high heterogeneity [75, 76]. The stability of the results was assessed using sensitivity analysis [77]. The Begg's and Egger's tests (a p -value < 0.05 was considered statistically significant) and the "trim-and-fill" method were used to assess publication bias [78–80]. Univariate meta-regression and subgroup analyses were performed to investigate associations between the effect size and the following parameters: year of publication, geographical area where the study was conducted, sample size, age, sex distribution, CRP, ESR, RA duration, DAS-28, sample matrix (serum or plasma), analytical method, and the use of methotrexate, glucocorticoids, and

DMARDs. All statistical analyses were performed using Stata 14 (Stata Corp., College Station, TX, USA).

Results

Study selection

Our search identified 2055 articles. Of them, 2004 were excluded following the initial screening as they were either duplicates or not relevant. A full-text review of the remaining 51 articles led to the further exclusion of 5 studies because of duplicate data, 4 because they were not case-control, 2 because they had missing data, and 1 because it was not written in English. Therefore, 39 studies were selected for analysis (Fig. 1 and Table 1) [72, 81–118]. The initial

NR, not reported; M/F, male to female ratio; VCAM-1, vascular cell adhesion molecule-1; ICAM-1, intercellular adhesion molecule-1; PECAM-1, platelet endothelial cell adhesion molecule-1

level of certainty was rated as low (rating 2) given the cross-sectional design of all studies.

ICAM-1

Twenty-four studies investigated ICAM-1 in a total of 1857 RA patients (mean age 52 years, 84% females) and 1476 healthy controls (mean age 48 years, 81% females) [81–86, 88, 89, 91, 92, 94, 97, 100, 101, 103–105, 107, 109, 111, 114–116, 118]. Eighteen studies were conducted in Europe [82–86, 88, 89, 91, 94, 100, 103, 104, 109, 111, 114–116, 118], 4 in America [81, 101, 105, 107], 1 in Asia [92], and 1 in Africa [97]. ICAM-1 was measured using an enzyme-linked immunosorbent assay (ELISA) in all but one study, which did not provide relevant details regarding the analytical method used [100]. Eighteen studies measured ICAM-1 in serum [81–86, 88, 89, 91, 92, 94, 105, 107, 109, 111, 114, 116, 118], 2 in plasma [104, 115], while the remaining 4 did not provide relevant information [97, 101, 103, 113]. RA duration was reported in 18 studies and ranged between 0.25 and 23 years [81, 82, 84, 85, 88, 89, 92, 94, 97, 100, 101, 103, 105, 109, 111, 114, 115, 118], whereas DAS-28, reported in six studies, ranged between 2.8 and 6.23 [103, 105, 109, 114, 116, 118]. Eleven studies reported data on methotrexate treatment [85, 86, 88, 91, 92, 94, 104, 111, 114, 116, 118], 18 on glucocorticoid treatment [81, 84, 86, 88, 91, 92, 94, 97, 100, 101, 103–105, 109, 114, 116, 118], and 14 on DMARDs treatment [81, 84, 86, 88, 89, 91, 94, 97, 100, 103, 105, 109, 116, 118]. The risk of bias was low in 11 studies [89, 97, 100, 101, 104, 105, 107, 109, 111, 114, 116], moderate in 12 [81–86, 88, 91, 92, 94, 115, 118], and high in the remaining 1 [103] (Table 2).

The forest plot showed that RA patients had significantly higher ICAM-1 concentrations when compared to healthy controls (SMD=0.81, 95% CI 0.62–1.00, $p < 0.001$; $I^2 = 83.0%$, $p < 0.001$; Fig. 2). The results were stable in sensitivity analysis, with pooled SMD values ranging between 0.68 and 0.84 (Supplementary Fig. S1). There was significant publication bias according to the Begg's test ($p = 0.003$) and the Egger's test ($p = 0.007$). The "trim-and-fill" method identified six missing studies to be added to the left side of the funnel plot to ensure symmetry (Supplementary Fig. S2). The resulting effect size remained significant (SMD=0.60, 95% CI 0.38–0.81, $p < 0.001$).

In meta-regression, there were non-significant associations between the effect size and age ($t = 0.50$, $p = 0.62$), sex distribution ($t = -0.81$, $p = 0.43$), publication year ($t = -0.81$, $p = 0.43$), number of participants ($t = -1.29$, $p = 0.21$), CRP ($t = 1.41$, $p = 0.19$), ESR ($t = 1.08$, $p = 0.31$), RA duration ($t = -1.20$, $p = 0.25$), or use of methotrexate ($t = -0.96$, $p = 0.36$), and DMARDs ($t = -0.49$, $p = 0.63$). By contrast, there was a significant inverse association between the effect size and the use of glucocorticoids

($t = -2.44$, $p = 0.027$) (Fig. 3a, b). In subgroup analysis, there were non-significant differences ($p = 0.70$) in pooled SMD between European (SMD=0.72, 95% CI 0.56–0.88, $p < 0.001$; $I^2 = 67.6%$, $p < 0.001$) and American studies (SMD=0.62, 95% CI 0.46–0.79, $p < 0.001$; $I^2 = 0.0%$, $p = 0.69$; Supplementary Fig. S3) with a virtually absent heterogeneity in the American subgroup. Similarly, there were non-significant differences ($p = 0.83$) in pooled SMD between studies measuring serum (SMD=0.93, 95% CI 0.67–1.18, $p < 0.001$; $I^2 = 86.4%$, $p < 0.001$) and plasma (SMD=0.86, 95% CI 0.62–1.11, $p < 0.001$; $I^2 = 0.0%$, $p = 0.58$; Supplementary Fig. S4), with a virtually absent heterogeneity in the plasma subgroup.

The overall level of certainty was upgraded to moderate (rating 3) after considering the low-moderate risk of bias in most studies (no change), the high but partly explainable heterogeneity (no change), the lack of indirectness (no change), the relatively large effect size (SMD=0.81, upgrade one level) [119], and the presence of publication bias which was addressed with the "trim-and-fill" method (no change).

VCAM-1

Twenty studies (21 comparator groups) investigated VCAM-1 in a total of 1446 RA patients (mean age 50 years, 81% females) and 1044 healthy controls (mean age 48 years, 79% females) [72, 83, 86, 88, 93, 97, 98, 100, 103–107, 109–112, 116–118]. Fourteen studies were conducted in Europe [83, 86, 88, 98, 100, 103, 104, 106, 109–112, 116, 118], 3 in Africa [93, 97, 117], 2 in America [105, 107], and 1 in Asia [72]. VCAM-1 was measured using an ELISA assay in all but one study for all studies except for one in which authors did not declare the method employed [100]. Fourteen studies investigated ICAM-1 in serum [72, 83, 86, 88, 93, 98, 105, 107, 109–111, 116–118] and 2 in plasma [104, 112]. No relevant information regarding the matrix analysed was provided in the remaining four studies [97, 100, 103, 106]. RA duration was reported in 12 studies and ranged between 0.25 and 23 years [88, 93, 97, 98, 100, 103, 105, 109–112, 118], whereas the DAS-28 was reported in 11 study comparators and ranged between 2.3 and 6.23 [98, 103, 105, 106, 109, 110, 112, 116–118]. The use of methotrexate was reported in 10 studies [72, 86, 88, 98, 104, 110, 111, 116–118], glucocorticoids in 14 [72, 86, 88, 97, 100, 103–106, 109, 112, 116–118], and DMARDs in 13 [72, 86, 88, 93, 97, 100, 103, 105, 106, 109, 110, 116, 117]. The risk of bias was low in 13 studies [93, 97, 98, 100, 104, 105, 107, 109–112, 116, 117], moderate in 4 [83, 86, 88, 118], and high in the remaining 3 [72, 103, 106] (Table 2).

The forest plot showed that VCAM-1 concentrations were significantly higher in RA patients when compared to controls (SMD=1.17, 95% CI 0.73–1.61, $p < 0.001$; $I^2 = 95.8%$, $p < 0.001$; Fig. 4). The pooled SMD values were stable in

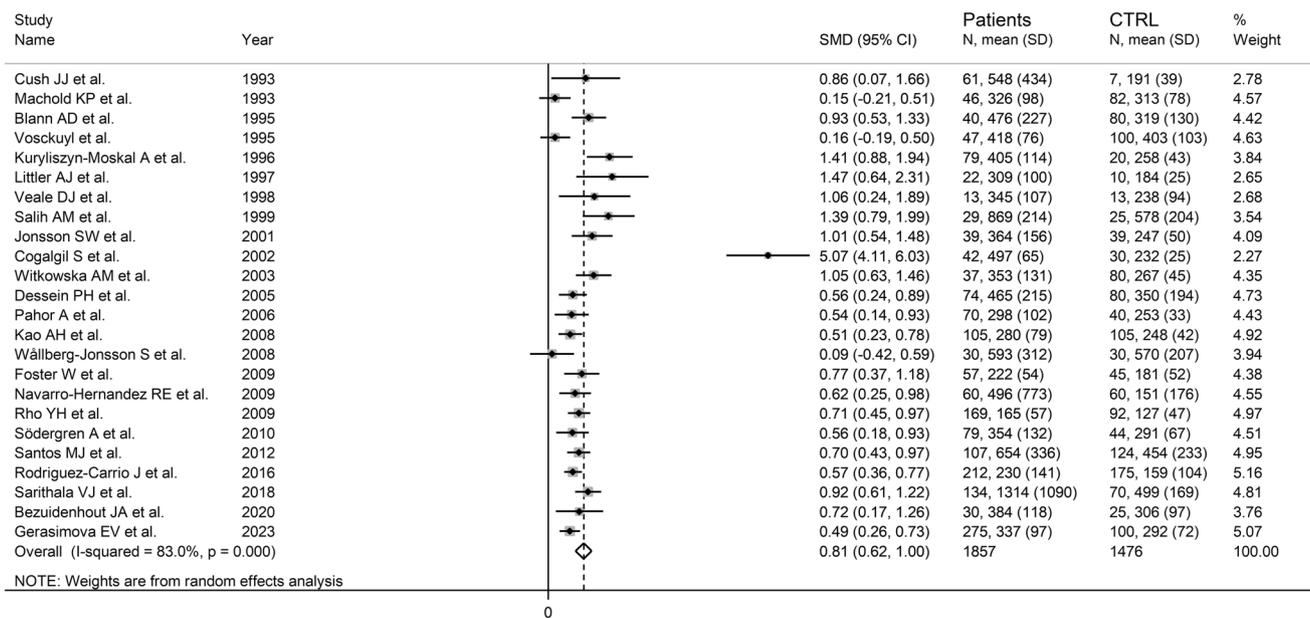

Fig. 2 Forest plot of studies investigating ICAM-1 in RA patients and healthy controls

sensitivity analysis, ranging between 0.94 and 1.27 (Supplementary Fig. S5). There was a significant publication bias (Begg’s test, $p=0.006$, and Egger’s test, $p=0.009$). The “trim-and-fill” method identified eight missing studies to be added to the left side of the funnel plot to ensure symmetry (Supplementary Fig. S6). However, the resulting effect size was no longer significant (SMD=0.39, 95% CI -0.11 to 0.88, $p=0.12$).

Non-significant associations were observed in the meta-regression between the effect size and age ($t=-0.86$, $p=0.40$), sex distribution ($t=1.38$, $p=0.19$), year of publication ($t=0.78$, $p=0.45$), sample size ($t=-0.33$, $p=0.74$), CRP ($t=1.03$, $p=0.33$), RA duration ($t=-0.10$, $p=0.92$), or use of methotrexate ($t=-1.62$, $p=0.14$) and glucocorticoids ($t=-1.05$, $p=0.32$). However, there was a trend toward a significant association between the effect size and DMARDs use ($t=-2.00$, $p=0.07$) and a significant association between SMD and ESR ($t=2.30$, $p=0.047$; Fig. 5a, b). In subgroup analysis, there was a significant difference ($p<0.001$) in pooled SMD between American (SMD=0.26, 95% CI -0.20 to 0.71, $p=0.27$; $I^2=76.2%$, $p=0.041$), European (SMD=0.80, 95% CI 0.36–1.24, $p<0.001$; $I^2=93.2%$, $p<0.001$), and African studies (SMD=1.77, 95% CI 1.21–2.33, $p<0.001$; $I^2=82.7%$, $p<0.001$; Fig. 6). By contrast, there were non-significant differences ($p=0.63$) in pooled SMD between studies investigating serum (SMD=1.18, 95% CI 0.63–1.73, $p<0.001$; $I^2=96.3%$, $p<0.001$) and plasma (SMD=0.61, 95% CI 0.29–0.92, $p=0.22$; $I^2=0.0%$, $p=0.455$; Supplementary Fig. S7), with a virtual absence of heterogeneity in the plasma subgroup.

The overall level of certainty remained low (rating 2) after considering the low–moderate risk of bias in most studies (no change), the high but partly explainable heterogeneity (no change), the lack of indirectness (no change), the relatively large effect size (SMD=1.17, upgrade one level) [119], and the presence of publication bias which was not fully addressed with the “trim-and-fill” method (downgrade one level).

PECAM-1

Two studies, one conducted in Europe [103], and the other in Asia [113], investigated PECAM-1 in a total of 130 RA patients (mean age 55 years, 80% females) and 124 healthy controls (mean age 43 years, 81% females). PECAM-1 was measured using an ELISA in both studies, in serum in one study [113], whereas the second study did not provide any details regarding the matrix assessed [103]. The risk of bias was low in one study [113] and high in the other [103] (Table 2). The forest plot showed that RA patients had significantly higher PECAM-1 concentrations when compared to controls (SMD=0.82, 95% CI 0.57–1.08, $p<0.001$; $I^2=0.0%$, $p=0.905$; Fig. 7). Sensitivity analysis, assessment of publication bias, and meta-regression and subgroup analysis could not be conducted because of the limited number of studies.

The overall level of certainty remained low (rating 2) after considering the low risk of bias in one of the two studies (no change), the virtually absent heterogeneity (no change), the lack of indirectness (no change), the relatively large effect size (SMD=0.82, upgrade one level) [119], and the lack of assessment of publication bias (downgrade one level).

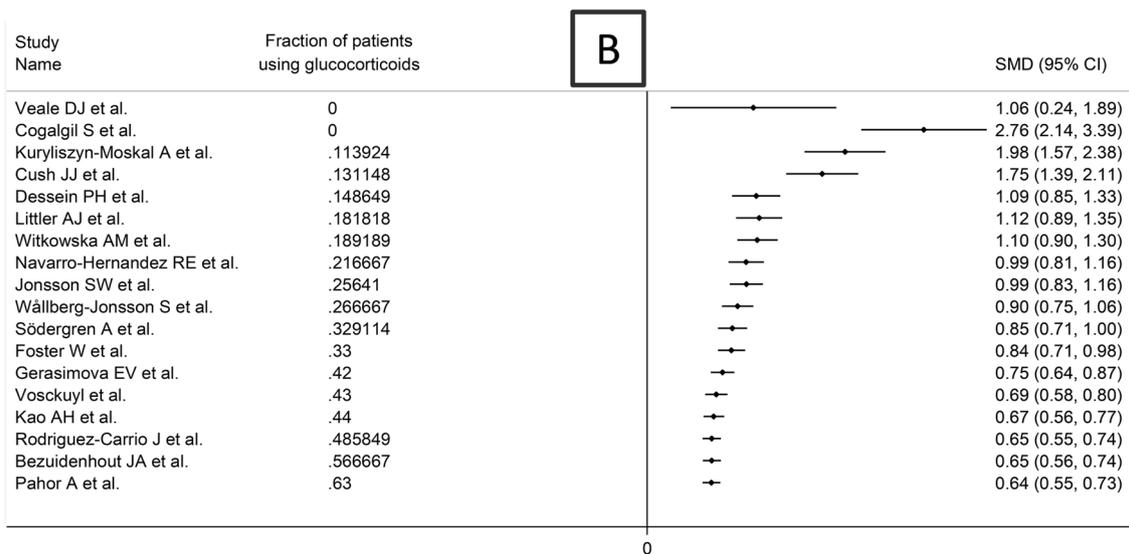

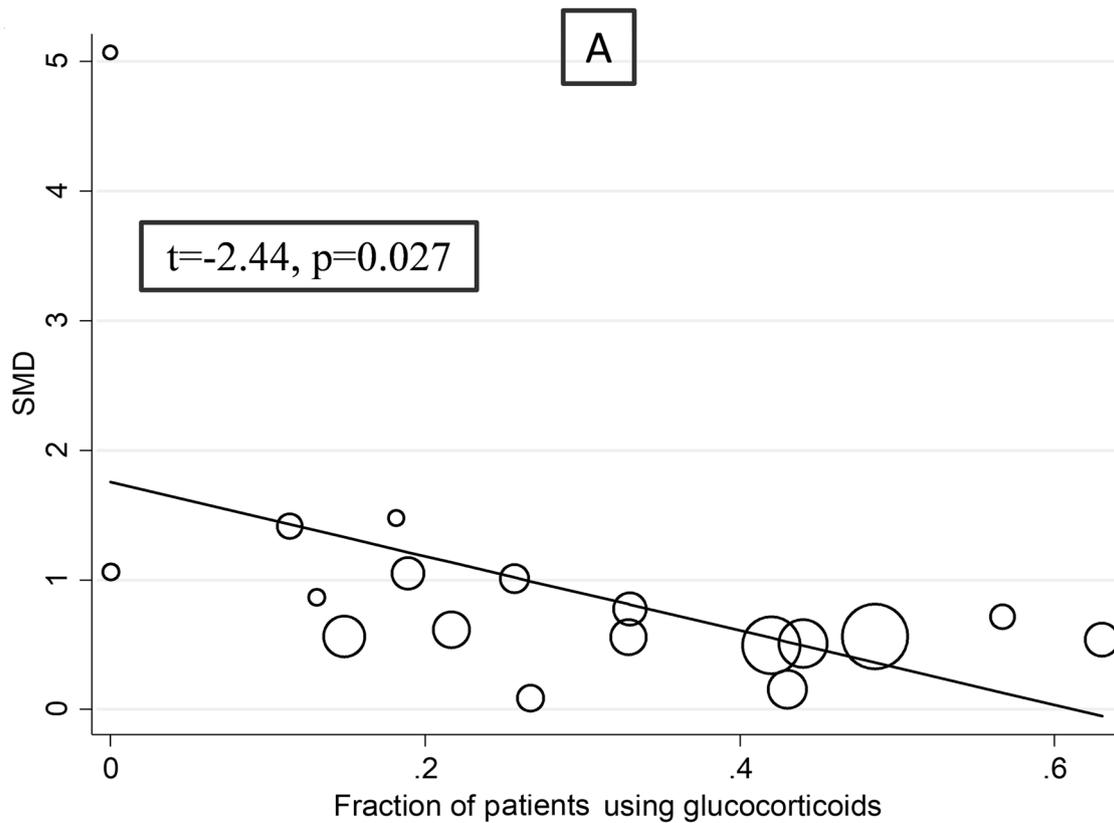

Fig. 3 Bubble plot reporting univariate meta-regression analysis between the effect size and the proportion of patients using glucocorticoids (**A**) and cumulative meta-analysis of ICAM-1 concentrations based on the proportion of patients using glucocorticoids (**B**)

E-selectin

Eighteen studies investigated E-selectin in a total of 831 RA patients (mean age 53 years, 78% females) and 720 healthy controls (mean age 50 years, 72% females) [83, 84, 86, 88,

89, 91, 93, 95, 96, 99, 102–104, 106–109, 112]. Twelve studies were conducted in Europe [83, 84, 86, 88, 89, 91, 103, 104, 106, 108, 109, 112], 2 in America [99, 107], 2 in Asia [95, 102], and 2 in Africa [93, 96]. E-selectin was measured using an ELISA in all studies. Measurements

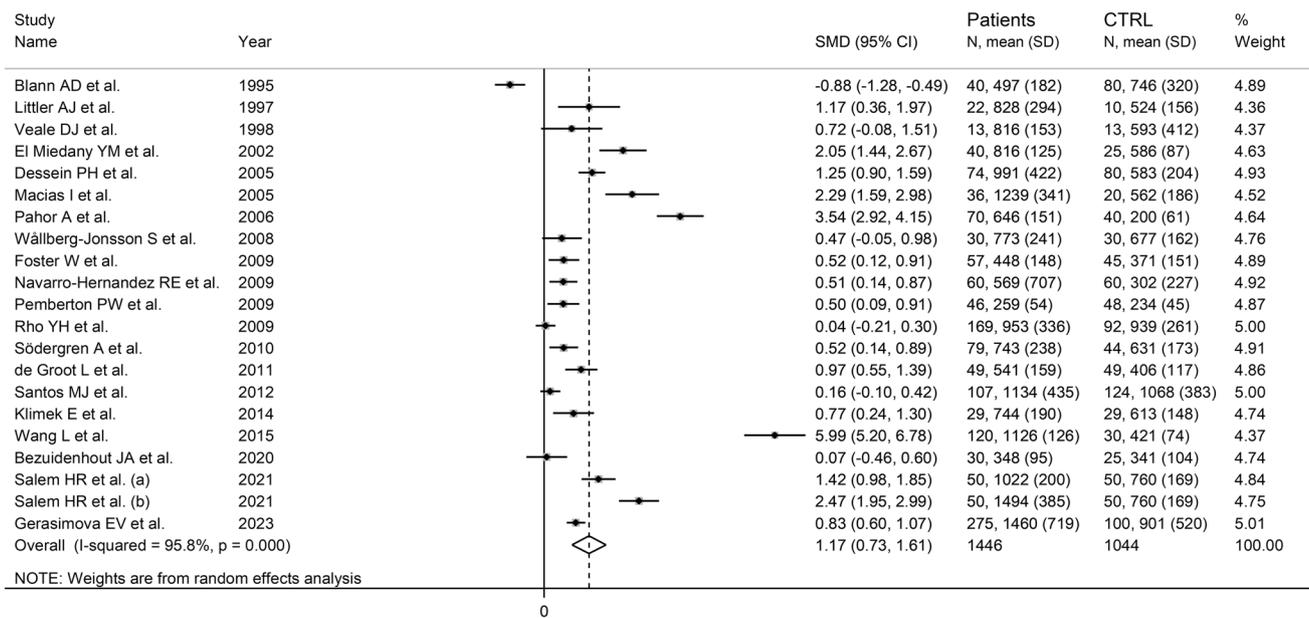

Fig. 4 Forest plot of studies investigating VCAM-1 investigating ICAM-1 in RA patients and controls

were performed in serum in 13 studies [83, 84, 86, 88, 89, 91, 93, 95, 96, 99, 107–109] and plasma in 3 [102, 104, 112]. Details regarding the matrix assessed were missing in two studies [103, 106]. RA duration, reported in 12 studies, ranged between 0.25 and 23 years [84, 88, 89, 93, 95, 96, 99, 102, 103, 108, 109, 112], whereas the DAS-28 reported in 6 studies ranged between 3.6 and 6.23 [99, 103, 106, 108, 109, 112]. Twelve studies reported data on glucocorticoid treatment [84, 86, 88, 91, 99, 102–104, 106, 108, 109, 112] and 12 on DMARDs treatment [84, 86, 88, 89, 91, 93, 99, 102, 103, 106, 108, 109]. The risk of bias was low in seven studies [89, 93, 99, 104, 107, 109, 112], moderate in eight [83, 84, 86, 88, 91, 95, 96, 102], and high in the remaining three [103, 106, 108].

The forest plot showed that E-selectin concentrations were significantly higher in RA patients when compared to controls (SMD = 0.64, 95% CI 0.42–0.86, $p < 0.001$; $I^2 = 75.0%$, $p < 0.001$; Fig. 8). Sensitivity analysis showed that the pooled SMD values were stable, ranging between 0.59 and 0.70 (Supplementary Fig. S8). There was no significant publication bias with the Begg's test ($p = 0.82$) or the Egger's test ($p = 0.98$). The "trim-and-fill" method identify two missing studies to be added to the left side of the funnel plot to ensure symmetry (Supplementary Fig. S9). However, the resulting effect size remained significant (SMD = 0.56, 95% CI 0.33–0.78; $p < 0.001$).

No significant associations were observed in meta-regression between the effect size and age ($t = 0.10$, $p = 0.92$), sex distribution ($t = -0.64$, $p = 0.54$), publication year ($t = -1.54$, $p = 0.14$), number of participants ($t = 0.33$, $p = 0.75$), CRP ($t = 1.06$, $p = 0.31$), ESR

($t = 1.70$, $p = 0.12$), RA duration ($t = 0.83$, $p = 0.43$), or use of DMARDs ($t = -0.54$, $p = 0.60$) and glucocorticoids ($t = -0.87$, $p = 0.41$). In subgroup analysis, there was a significant difference ($p = 0.02$) in pooled SMD between Asian (SMD = 0.43, 95% CI -0.11 to 0.96, $p = 0.12$; $I^2 = 38.1%$, $p = 0.204$), European (SMD = 0.51, 95% CI 0.23–0.79, $p < 0.001$; $I^2 = 76.0%$, $p < 0.001$), American (SMD = 0.82, 95% CI 0.50–1.14, $p < 0.001$; $I^2 = 50.2%$, $p = 0.156$), and African studies (SMD = 1.41, 95% CI 0.97–1.84, $p < 0.001$; $I^2 = 0.0%$, $p = 0.493$; Fig. 9), with a virtually absent heterogeneity in the African subgroup. By contrast, there were non-significant differences ($p = 0.61$) in pooled SMD values between studies investigating serum (SMD = 0.65, 95% CI 0.36–0.95, $p < 0.001$; $I^2 = 81.4%$, $p < 0.001$) and plasma (SMD = 0.51, 95% CI 0.23–0.79, $p < 0.001$; $I^2 = 0.0%$, $p = 0.405$; Supplementary Fig. S10), with a virtually absent heterogeneity in the plasma subgroup.

The overall level of certainty remained low (rating 2) after considering the low–moderate risk of bias in most studies (no change), the moderate and partially explained heterogeneity (no change), the lack of indirectness (no change), the moderate effect size (SMD = 0.64, no change) [119], and the absence of publication bias (no change).

L-selectin

Six studies, all conducted in Europe, investigated L-selectin in a total of 230 RA patients (mean age 51 years, 80% females) and 170 healthy controls (mean age 48 years, 81% females) [86, 90, 95, 103, 108, 109]. L-selectin was measured in serum by ELISA in all studies, except one study

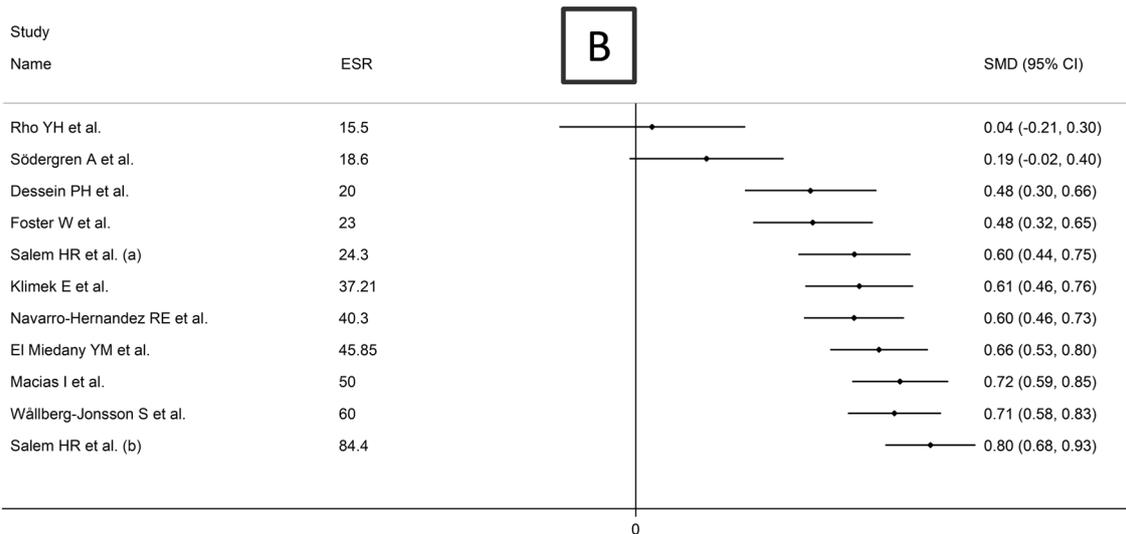

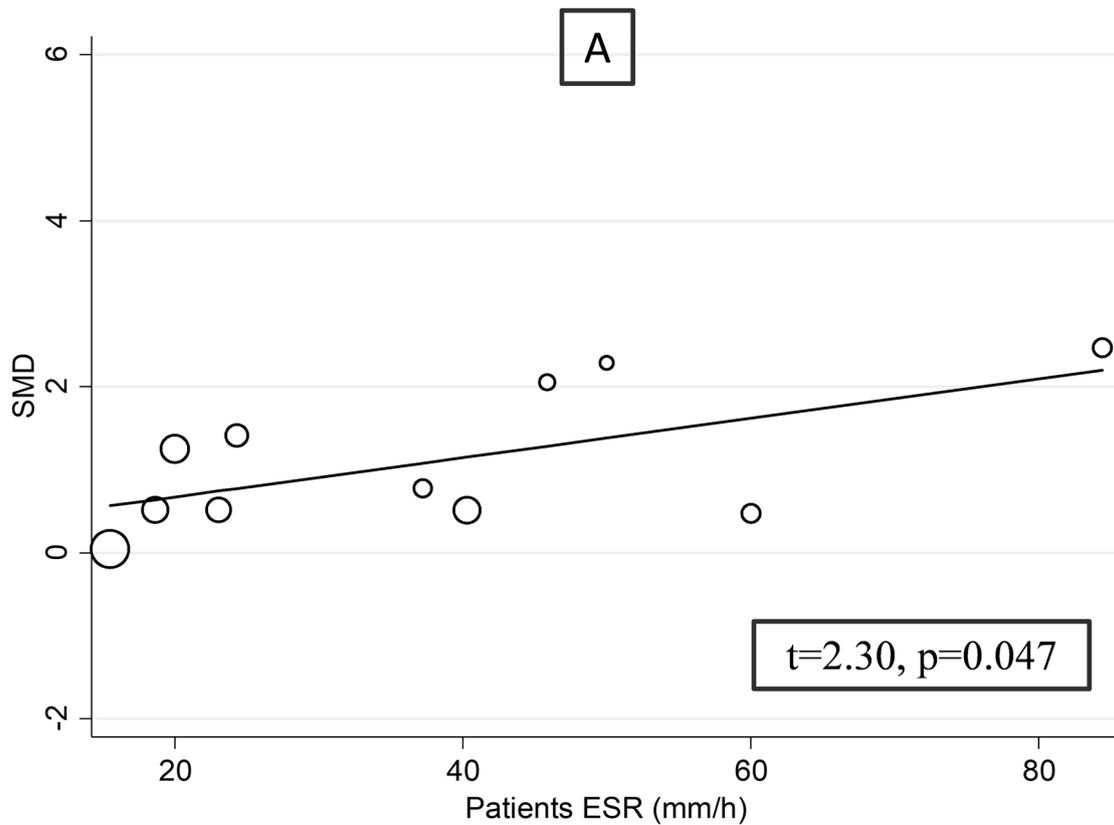

Fig. 5 Bubble plot reporting univariate meta-regression analysis between the effect size and ESR values of RA patients (**A**) and cumulative meta-analysis of VCAM-1 concentrations based on ESR values (**B**)

which did not provide relevant details regarding the matrix assessed [103]. The risk of bias was low in one study [109], moderate in three [86, 90, 95], and high in the remaining two [103, 108].

The forest plot showed the absence of significant between-group differences in L-selectin concentrations (SMD = 0.21, 95% CI -0.66 to 1.08, $p = 0.63$; $I^2 = 93.5\%$, $p < 0.001$; Fig. 10). Sensitivity analysis showed stability

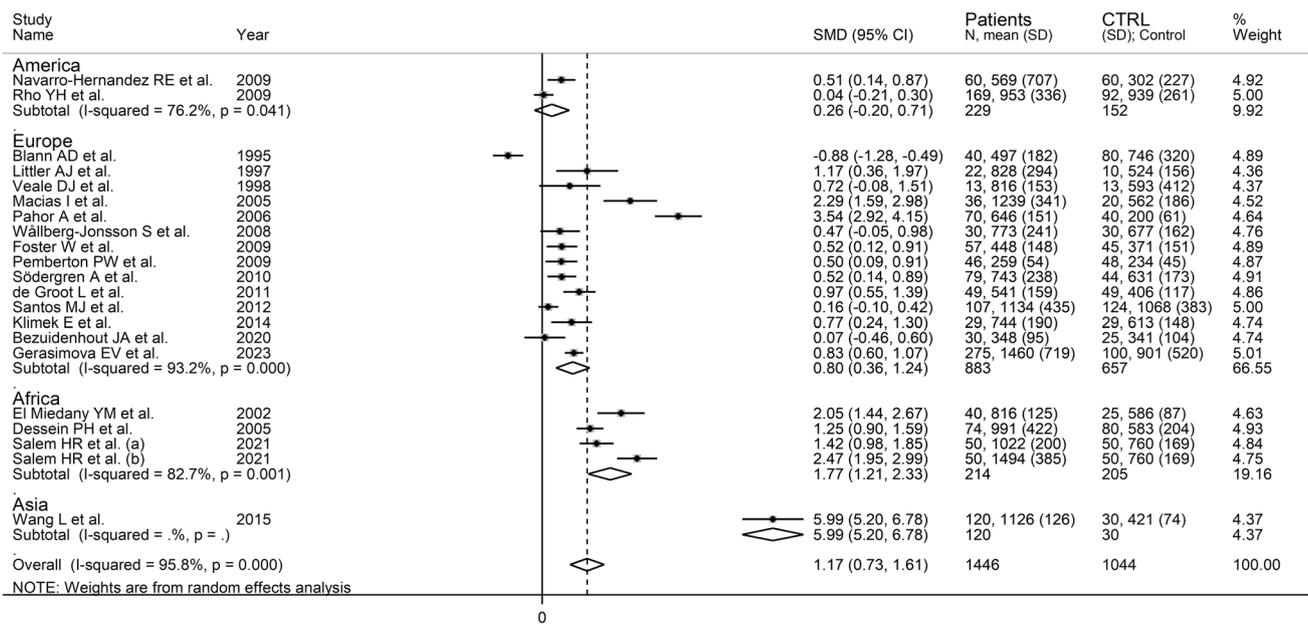

Fig. 6 Forest plot of studies investigating VCAM-1 in RA patients and controls according to study continent

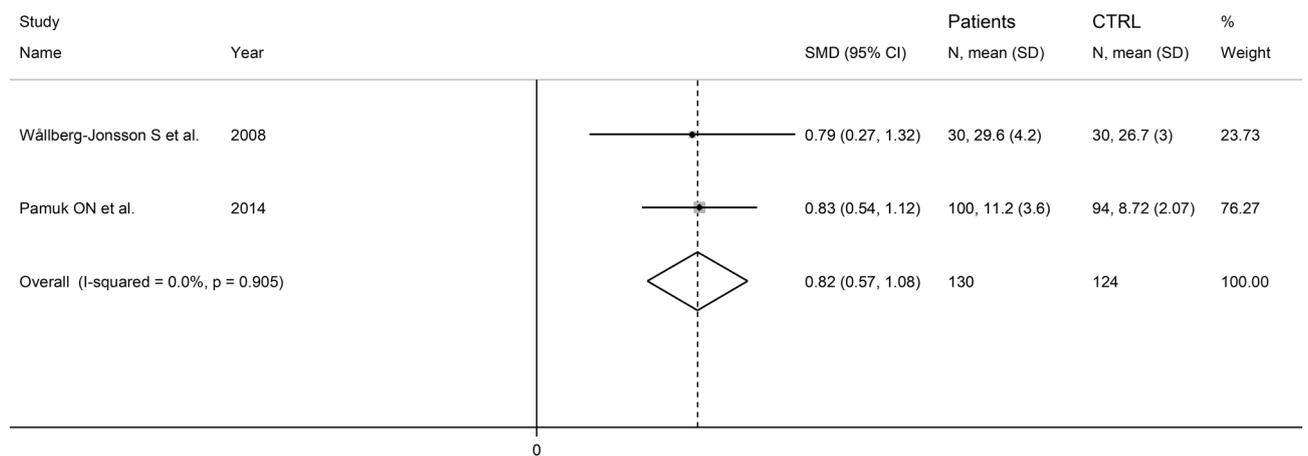

Fig. 7 Forest plot of studies investigating PECAM-1 in RA patients and controls

of the results, with pooled SMD values ranging between -0.14 and 0.60 (Supplementary Fig. S11).

Assessment of publication bias, meta-regression and subgroup analysis could not be conducted because of the relatively small number of studies.

The overall level of certainty was downgraded to very low (rating 1) after considering the low-moderate risk of bias in most studies (no change), the high and unexplained heterogeneity (downgrade one level), the lack of indirectness (no change), the small effect size (SMD = 0.21, no change) [119], and the lack of assessment of publication bias (downgrade one level).

P-selectin

Eight studies investigated P-selectin in a total of 230 RA patients (mean age 53 years, 85% females) and 211 healthy controls (mean age 51 years, 87% females) [86–88, 90, 95, 103, 106, 108]. Six studies were conducted in Europe [86, 88, 90, 103, 106, 108], and two in Asia [87, 95]. P-selectin was measured using an ELISA assay in serum in four studies [86, 90, 95, 108] and in plasma in two studies [87, 88]. Two studies did not report relevant information regarding the matrix analyzed [103, 106]. The risk of bias was moderate in

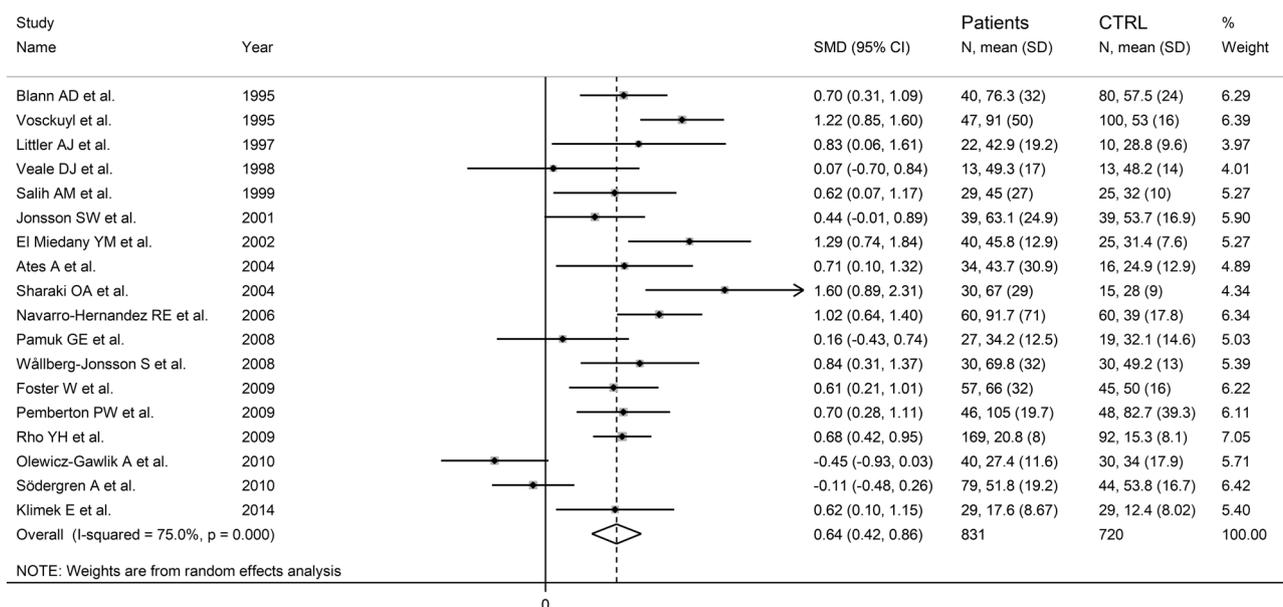

Fig. 8 Forest plot of studies investigating E-selectin in RA patients and controls

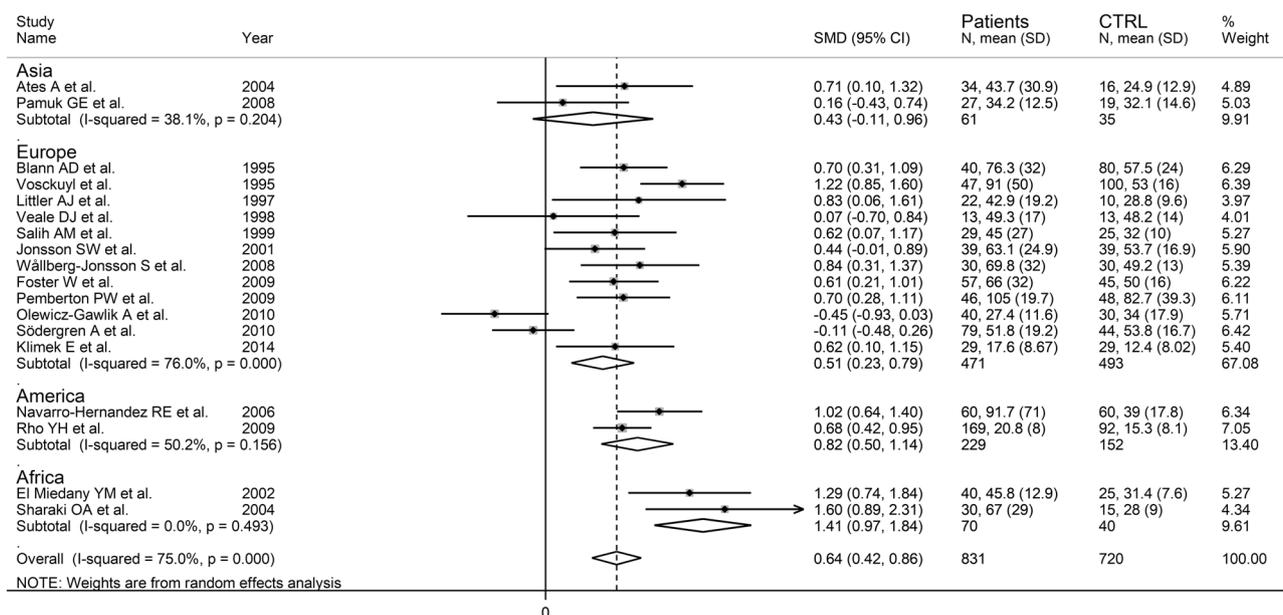

Fig. 9 Forest plot of studies investigating E-selectin in RA patients and controls according to study continent

five studies [86–88, 90, 95] and high in the other three [103, 106, 108] (Table 2).

The forest plot showed that P-selectin concentrations were significantly higher in RA patients when compared to controls (SMD = 1.06, 95% CI 0.50–1.60, $p < 0.001$; $I^2 = 84.8%$, $p < 0.001$; Fig. 11). The pooled SMD values were stable in sensitivity analysis and ranged between 0.81 and 1.21 (Supplementary Fig. S12). Assessment of

publication bias and meta-regression analysis could not be performed because of the limited number of studies.

In subgroup analysis, the pooled SMD was significantly different in European studies (SMD = 0.88, 95% CI 0.39–1.38, $p < 0.001$; $I^2 = 77.6%$, $p < 0.001$), but not in Asian studies (SMD = 1.63, 95% CI –0.71 to 3.97, $p = 0.17$; $I^2 = 95.0%$, $p < 0.001$; Fig. 12). A significant difference ($p = 0.045$) in pooled SMD was observed between

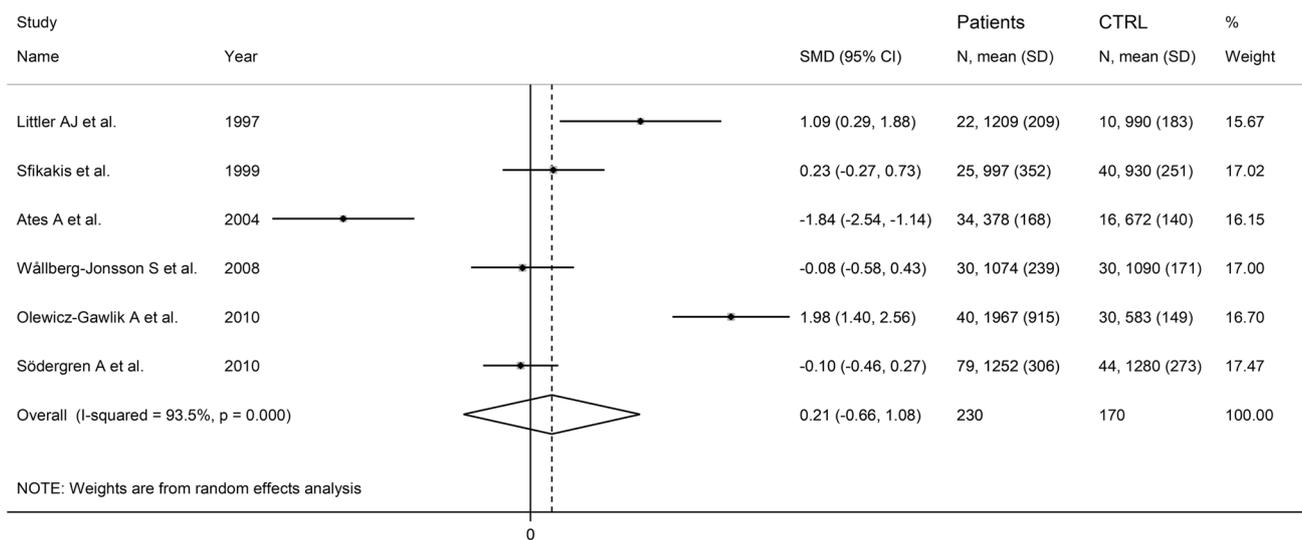

Fig. 10 Forest plot of studies investigating L-selectin in RA patients and controls

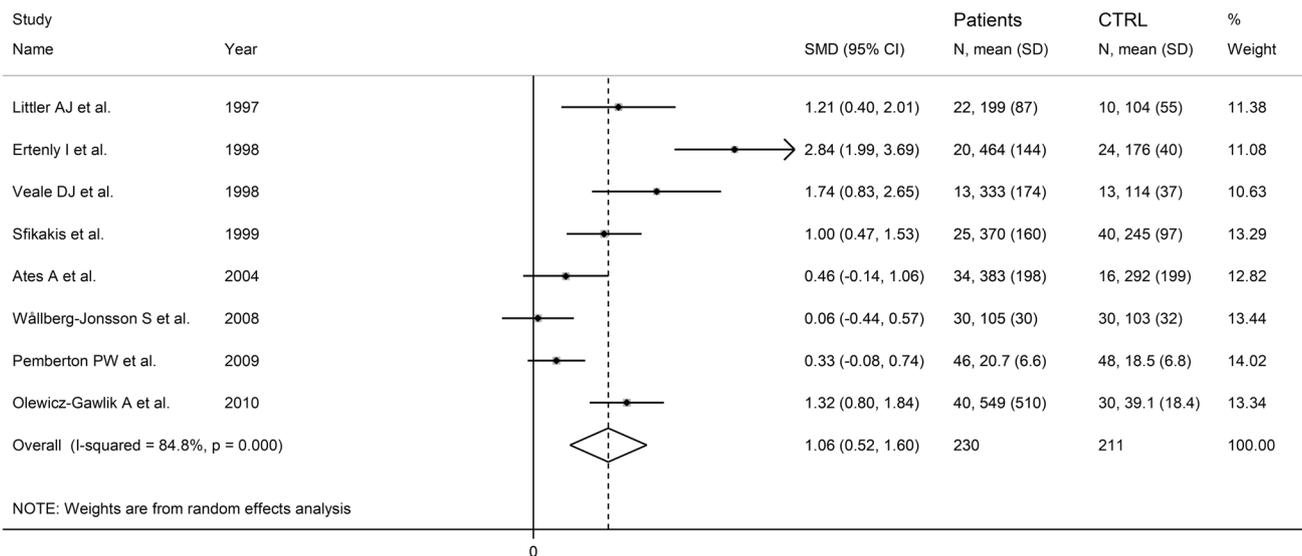

Fig. 11 Forest plot of studies investigating P-selectin in RA patients and controls

studies on serum (SMD = 0.99, 95% CI 0.61–1.37, $p < 0.001$; $I^2 = 37.5%$, $p = 0.187$), and those on plasma (SMD = 2.31, 95% CI 1.23–3.39, $p < 0.001$; $I^2 = 66.7%$, $p = 0.083$, Fig. 13), with a decreased between-study variance in the serum subgroup.

The overall level of certainty remained low (rating 2) after considering the moderate risk of bias in most studies (no change), the high but partially explained heterogeneity (no change), the lack of indirectness (no change), the large effect size (SMD = 1.06, upgrade one level) [119], and the lack of assessment of publication bias (downgrade one level).

Discussion

Our study supports a significant pathophysiological role of cell adhesion molecules in mediating the interplay between RA and atherosclerosis. Specifically, RA patients had significantly higher concentrations of VCAM-1, ICAM-1, E-selectin, and P-selectin, but not L-selectin, when compared to healthy controls. The corresponding pooled SMD values were stable in sensitivity analysis. In meta-regression and subgroup analysis, we observed significant associations between the effect size of ICAM-1 and the use

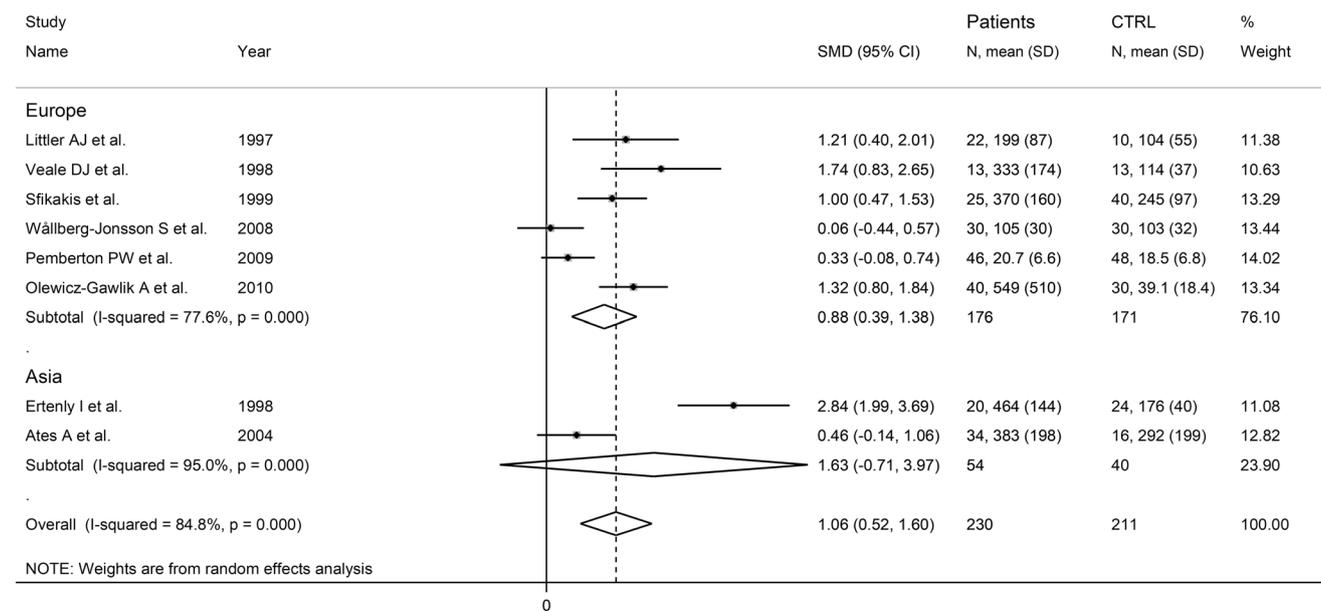

Fig. 12 Forest plot of studies investigating P-selectin in RA patients and controls according to study continent

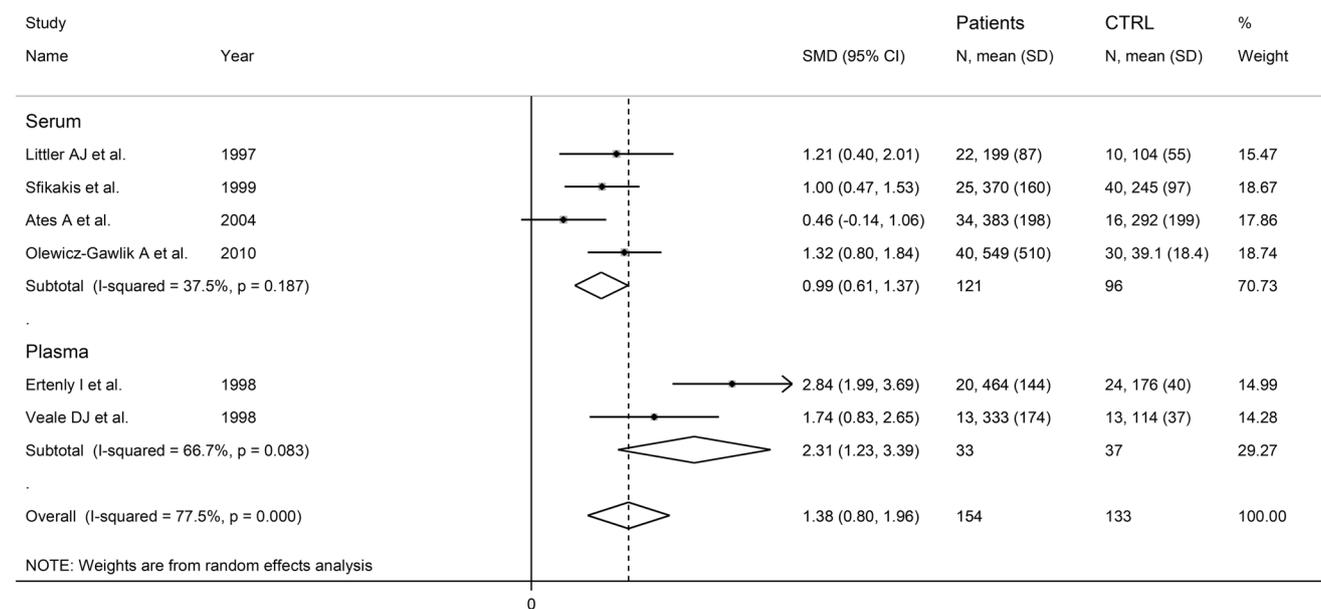

Fig. 13 Forest plot of studies investigating P-selectin in RA patients and controls according to the type of matrix assessed (serum or plasma)

of glucocorticoids, between the effect size of VCAM-1 and ERS, between the effect size of VCAM-1, E-selectin, and P-selectin and study continent, and between the effect size of P-selectin and the type of matrix assessed (plasma vs. serum).

The atherosclerotic process is characterized by a significant dysregulation of inflammatory and immune cellular and molecular pathways [120, 121]. As part of such dysregulation, the abnormal interaction between leukocytes and

endothelial cells, mediated by cell adhesion molecules, plays a critical role in the early stages of plaque formation [122]. The consequent accumulation of leukocytes in the intima layer, in turn, facilitates their uptake of lipoprotein particles and subsequent differentiation into macrophages, precursors of foam cells, critically involved in plaque growth [123–125]. Accordingly, several studies have reported the upregulation of immunoglobulin-like adhesion molecules and selectins in experimental models of atherosclerosis [55, 126–129].

The significant elevations in VCAM-1, ICAM-1, E-selectin, and P-selectin in RA patients observed in our systematic review and meta-analysis reflect a state of endothelial activation and dysregulation, in the context of excessive inflammation and oxidative stress. Furthermore, they suggest the potential utility of measuring cell adhesion molecules for cardiovascular risk stratification in this patient group. The lack of significant between-group differences in the concentrations of L-selectin, a critical regulator of leukocyte tethering, rolling, adhesion, migration and signaling and monocyte protrusion during trans-endothelial migration [58, 130], indicates a different pathophysiological role of this selectin in RA. However, the relatively small number of studies investigating L-selectin warrant further research to confirm this proposition. Furthermore, the lack of significant associations in meta-regression analysis between the effect size of the between-group differences in cell adhesion molecules and RA duration or DAS-28 also indicates that alterations in cell adhesion molecules are already present in patients with short disease duration and relatively low disease activity.

Another interesting observation was the significant inverse association between the effect size of ICAM-1 and the use of glucocorticoids. This finding is in line with the results of *in vitro* studies reporting that dexamethasone, a potent glucocorticoid, inhibits the expression of E-selectin and ICAM-1 in endothelial cells following treatment with the endotoxin lipopolysaccharide, a known stimulator of acute pro-inflammatory responses [131]. Other studies have reported a similar effect of glucocorticoids on the expression of cell adhesion molecules [132–134]. Accordingly, the observation of a significant positive association between the effect size of VCAM-1 and ESR support the traditional proposition that endothelial activation and dysregulation are intimately linked with excess inflammation [135–137]. However, as such associations were observed with specific cell adhesion molecules, *i.e.*, ICAM-1 and VCAM-1, further research is warranted to confirm these findings in patients with RA.

In subgroup analysis, a significant association was observed the SMD of VCAM-1, E-selectin, and P-selectin and study continent, suggesting the presence of ethnic-related differences in cell adhesion molecules. Specifically, the SMD of VCAM-1 was progressively higher in American, European, and African studies, the SMD of E-selectin was progressively higher in Asian, European, American, and African studies, and the SMD of P-selectin was significant in European but not Asian studies. In an epidemiological study conducted in England, participants of African background had significantly lower concentrations of VCAM-1 and ICAM-1 when compared to Caucasian and South Asian participants [138]. Relatively higher VCAM-1 concentrations in Caucasians vs. African Americans, Hispanics, and Chinese participants have also been reported in a North American study [139]. By contrast,

studies have generally failed to identify the presence of significant ethnic-related differences in circulating selectins [140–143]. It is important to emphasize however that these studies generally investigated patients with relatively low cardiovascular risk and without autoimmune diseases, suggesting that additional studies are required to investigate possible ethnic-related differences in the concentrations of cell adhesion molecules in patients with RA and other rheumatic diseases.

Strengths of our systematic review and meta-analysis include the combined assessment of a range of immunoglobulin-like adhesion molecules and selectins in patients with RA in a relatively large number of studies, and the robust assessment of the risk of bias and the certainty of evidence for each adhesion molecule. A possible limitation is related to the high heterogeneity observed for the studied adhesion molecules. However, specific sources of heterogeneity were identified for ICAM-1 (study continent and matrix assessed), VCAM-1 (matrix assessed), E-selectin (study continent and matrix assessed), and P-selectin (study continent).

In conclusion, our systematic review and meta-analysis suggests that cell adhesion molecules play an important pathophysiological role in the interplay between RA and atherosclerosis, including patients with relatively short RA duration and low disease activity. Further studies are warranted to investigate the potential utility of cell adhesion molecules in cardiovascular risk stratification and the possible effects of immunomodulatory and anti-inflammatory treatments.
