JHEP Reports 2024. <https://doi.org/10.1016/j.jhepr.2024.101019>

Background & Aims: Recent studies have implicated platelets, particularly α -granules, in the development of non-alcoholic steatohepatitis (NASH). However, the specific mechanisms involved have yet to be determined. Notably, thrombospondin 1 (TSP1) is a major component of the platelet α -granules released during platelet activation. Hence, we aimed to determine the role of platelet-derived TSP1 in NASH.

Methods: Platelet-specific Tsp1 knockout mice (TSP1^{4pf4}) and their wild-type littermates (TSP1^{F/F}) were used. NASH was induced by feeding the mice with a diet enriched in fat, sucrose, fructose, and cholesterol (AMLN diet). A human liver NASH organoid model was also employed.

Results: Although TSP1 deletion in platelets did not affect diet-induced steatosis, TSP1^{4pf4} mice exhibited attenuated NASH and liver fibrosis, accompanied by improvements in plasma glucose and lipid homeostasis. Furthermore, $TSP1^{4p}$ mice showed reduced intrahepatic platelet accumulation, activation, and chemokine production, correlating with decreased immune cell infiltration into the liver. Consequently, this diminished proinflammatory signaling in the liver, thereby mitigating the progression of NAFLD. Moreover, in vitro data revealed that co-culturing TSP1-deficient platelets in a human liver NASH organoid model attenuated hepatic stellate cell activation and NASH progression. Additionally, TSP1-deficient platelets play a role in regulating brown fat endocrine function, specifically affecting Nrg4 (neuregulin 4) production. Crosstalk between brown fat and the liver may also influence the progression of NAFLD.

Conclusions: These data suggest that platelet a-granule-derived TSP1 is a significant contributor to diet-induced NASH and fibrosis, potentially serving as a new therapeutic target for this severe liver disease.

Impact and implications: Recent studies have implicated platelets, specifically α -granules, in the development of non-alcoholic steatohepatitis, yet the precise mechanisms remain unknown. In this study, through the utilization of a tissuespecific knockout mouse model and human 3D liver organoid, we demonstrated that platelet α -granule-derived TSP1 significantly contributes to diet-induced non-alcoholic steatohepatitis and fibrosis. This contribution is, in part, attributed to the regulation of intrahepatic immune cell infiltration and potential crosstalk between fat and the liver. These findings suggest that platelet-derived TSP1 may represent a novel therapeutic target in non-alcoholic fatty liver disease.

Introduction

The pathogenesis of non-alcoholic fatty liver disease (NAFLD)/ non-alcoholic steatohepatitis (NASH) is complex.¹ Immune cellmediated inflammation has emerged as a significant contributor to NAFLD progression and fibrosis development. $2-5$ Although macrophages and T cells have been extensively studied in NAFLD, the role of platelets in NASH development has

gained recognition. $6-10$ $6-10$ In addition to their well-known role in regulating blood hemostasis, accumulating evidence suggests that platelets are significant contributors to NAFLD/NASH. $6-10$ $6-10$ Previous studies have reported an association between the platelet count and NAFLD.^{11-[14](#page-9-3)} Furthermore, studies using rodent models have demonstrated that anti-platelet therapy can alleviate NASH development $⁶$ $⁶$ $⁶$ and reduce liver damage in pa-</sup> tients with NAFLD.¹⁵ A recent study has revealed that platelets accumulate and adhere to Kupffer cells, promoting liver inflam-mation through a GPIb_x-dependent mechanism.^{[8](#page-9-5)} Platelet cargo, particularly a-granules, has been implicated in NASH progression.⁸ However, the specific constituents of platelet-derived a-granules involved in NASH progression have yet to be fully characterized.

Keywords: Platelet α granule; TSP1; NASH; brown adipocytes; organ crosstalk.

Thrombospondin 1 (TSP1) is a large glycoprotein with a molecular weight of 420-450 kDa that forms a homotrimeric structure. It constitutes a substantial portion, approximately 20%, of the total content of human platelet α granules, making it one of the most abundant proteins in these granules. TSP1 is rapidly released upon platelet activation^{[16](#page-9-6)} and also secreted by various cell types. 17 In addition to regulation of hemostasis, previous studies from our lab established an important role of TSP1 in obesity-associated metabolic diseases including NAFLD/ NASH. $18-23$ $18-23$ We have demonstrated that TSP1 is an important regulator of monocyte/macrophage functions. It stimulates monocyte/macrophage migration and proinflammatory activation, which contributes to obesity-related chronic inflammation and NAFLD/NASH[.23](#page-9-9),[24](#page-9-10) Although recent advances have illustrated the role of TSP1 in metabolic diseases, the cellular sources of TSP1 that significantly affect the development and progression of NASH remain unresolved. With the recognition of platelets in NASH pathogenesis and the high abundance of TSP1 in platelet α granules, we hypothesize that TSP1 from platelet sources might be a significant contributor to NASH. The aim of this current study was to test this hypothesis.

In this study, for the first time, we investigated the role of platelet-derived TSP1 in a diet-induced NASH mouse model using platelet-specific TSP1-deficient mice as well as human NASH organoids. Although TSP1 deletion in platelets did not protect against diet-induced steatosis, it significantly attenuated liver inflammation and fibrosis, providing strong evidence that platelet-derived TSP1 is an important contributor to NAFLD progression.

Material and methods Mice and diet

All experiments involving mice were approved by the University of Kentucky Institutional Animal Care and Use Committee. Animals were housed in standard cages at 22 °C under a 12:12-h light-dark cycle. To produce platelet-specific TSP1-deficient mice (TSP1^{4pf4}), Tsp1 floxed mice generated in our laboratory^{[24](#page-9-10)} (TSP1^{F/}
^F) were crossbred with Pf4-Cre mice from Jax Lab for two generations. Male TSP1^{4pf4} mice and littermate controls (TSP1^{F/F}) were used in our studies. For dietary models, mice were fed a low-fat diet (LF, 10% kcal, D1250B, Research Diets, Inc, NJ) or AMLN diet (40% fat; 22% fructose and 2% cholesterol, D09100301, Research Diets, Inc, NJ) for 16 weeks (to induce simple steatosis) and 32 weeks (to induce NASH).

Metabolic analysis

Body weight was monitored weekly. Body composition (e.g., fat mass and lean mass) was measured using Echo-MRI. Glucose tolerance test and data analysis were performed as previously described.[25](#page-9-11) Indirect calorimetry was performed by placing mice in the Sable Promethion Metabolic Chamber.

Liver histology analysis and immunohistochemical staining

Liver histology (H&E staining) and the NAFLD activity score were assessed as previously described.^{26-[28](#page-9-12)} Sirius Red or Trichrome staining, provided by a Pathology Core at the University of Kentucky, was used to analyze liver fibrosis. For liver immunohistochemical staining, liver paraffin sections were stained with anti-CD41 antibody (Thermo Fisher Scientific; MA, USA), antineutrophil antibody [7/4] (ab53457) (Abcam; Cambridge CB20AX, UK), anti-p-selectin antibody (Novus Biologicals, CO,

USA), anti-CD4 antibody (Abcam; Cambridge CB20AX, UK), or anti-CD8 antibody (Novus Biologicals, CO, USA), followed by incubation with biotinylated secondary antibody, peroxidase substrate diaminobenzidine (Vector Lab) and counterstaining with hematoxylin. Images were captured by a Nikon Eclipse 55i microscope. Semi-quantification of neutrophil, CD4, or CD8 positive cells in liver sections was performed as previously described.[29](#page-10-0)

Lipid analysis

Total lipids from frozen liver were extracted as previously described.^{[30](#page-10-1)} Liver and plasma triacylglycerol and total cholesterol levels were measured enzymatically using kits from Wako Chemicals (Richmond, USA). Additionally, plasma from multiple mice (n = 5) in each group was pooled, and fast-performance liquid chromatography was used to determine plasma lipopro-tein distribution.^{[31](#page-10-2)}

Blood parameter analysis

At the end of the study, blood hematology analysis was performed using the Hemavet 950FS. Plasma alanine aminotransferase (ALT) levels were measured using ALT assay kits (Sigma-Aldrich, MD, USA). Plasma insulin levels were measured using an ELISA kit (Crystal Chem, IL, USA). PF4 levels in plateletrich plasma or platelet-poor plasma were measured using a mouse CXCL4/PF4 immunoassay kit (R&D system; MN, USA).

Liver RNA-Seq transcriptome sequencing

Liver bulk RNA sequencing was performed by Novogene (Sacremento, CA) NovaSeq PE150, for all 16 liver samples ($n = 4$ mice/ group), with an average read depth of 6G reads per sample. Reads were aligned using STAR 2.7.8a and quantified using the mouse reference genome mm10. Analysis of differentially expressed genes (DEGs) between groups of interest was conducted using the DESeq2 algorithm. DEGs were selected if the adjusted p value was less than 0.05 and the absolute value of logfold change was higher than 0.25. Based on the identified DEGs between groups of interest, enrichment analyses of gene ontology terms, the KEGG pathway, and the Reactome pathway were performed using Cluster Profiler R program package. Enrichment analysis results were filtered out if the adjusted p value was greater than 0.05. The data have been deposited in the Gene Expression Omnibus with accession number GSE250004.

Real-time quantitative PCR

Total RNA from the liver and other tissues was extracted, reverse transcribed to cDNA, subjected to quantitative PCR analysis using a MyiQ Real-time PCR Thermal Cycler (Bio-Rad) with SYBR Green PCR Master Kit (Qiagen, Valencia, CA) and normalized to β -actin mRNA levels as previously described.^{[23](#page-9-9)} All the primer sequences utilized in this study are listed in Table S1.

Western blotting

Proteins obtained from the liver or other tissues were separated using SDS-PAGE and subsequently transferred onto a nitrocellulose membrane. To determine protein expression, immunoblotting was performed using the following antibodies: anti-TSP1 (Novus Biologicals), anti-a-SMA (smooth muscle actin) $(Sigma-Aldrich)$, or anti- β -actin $(Sigma-Aldrich)$. The membranes were incubated with primary antibodies and then with appropriate secondary antibodies conjugated with horseradish

peroxidase. Labelled proteins were visualized using an enhanced chemiluminescence system (Pierce).

3D human NASH organoid model with or without platelet coculture

A 3D human NASH in vitro model was previously established in our lab.^{[29](#page-10-0)} Briefly, human hepatocytes (ATCC), THP1-derived macrophages (ATCC) and human stellate cells (Zenbio) were co-cultured to form 3D spheroids and then treated with NASHinducing media (DMEM media containing 1% BSA, palmitate [0.5 mM], high glucose [30 mM] and lipopolysaccharide [2 μ g/ ml]) for 5 days to induce the proinflammatory and profibrogenic phenotype. To determine the effect of TSP1-depleted platelets on NASH progression in liver organoids, purified platelets $(1x10^4)$ from wild-type (WT) or TSP1-deficient mice were added into 3D spheroids in the presence of NASH-inducing media for 5 days. After treatment, cells were harvested, and the expression of genes related to inflammation and fibrosis was determined by real-time PCR. Additionally, organoids were harvested for immunofluorescence staining with anti-α-SMA (Sigma, 1:100) and then secondary antibody-mouse-Alexa488. After staining,

slides were mounted with mounting medium containing DAPI. The images were captured with the Nikon A1R confocal microscope.

Statistical analysis

Statistical analysis was performed using Prism version 9.0 (GraphPad Software, San Diego, CA, USA). Data are expressed as mean values \pm SE. Two-tailed Student's t test was used to determine statistical significance between the two groups. Oneway ANOVA followed by Tukey's multiple comparison test or two-way ANOVA followed by Tukey's multiple comparison test was used for multi-group comparisons.

Results

Platelet-specific TSP1 deficiency failed to protect mice against diet-induced steatosis

TSP1 deficiency in platelets of $TSP1^{APf4}$ mice was confirmed through PCR and western blotting (Fig. S1A-C). TSP1 deficiency did not affect blood platelet counts (Fig. S1D, Table S2). Platelet aggregation and mouse tail bleeding time were also measured as

JHEP Reports

previously described 32 and were comparable between WT and knockout (KO) mice (Fig. S1E,F), Together, these data suggest that deletion of TSP1 in platelets does not affect hemostasis under physiological conditions.

To determine whether platelet TSP1 deficiency affects NAFLD development and progression, a mouse model of AMLN dietinduced NASH (obesity and insulin resistance) 33 was utilized. Simple steatosis was induced by feeding mice with the AMLN diet for 16 weeks. We observed that AMLN-fed TSP1 4Pf4 mice had slightly reduced body weight compared to AMLN-fed $TSP1^{F/F}$ mice ([Fig. 1](#page-2-0)A,B). Plasma ALT levels were also reduced in the AMLN-fed TSP1 4Pf4 mice [\(Fig. 1C](#page-2-0)). However, liver weight/body weight ratio, liver fat accumulation (demonstrated by Oil Red O staining), hepatic total cholesterol and triglyceride measurements, and glucose tolerance tests were comparable between the two genotypes after AMLN diet feeding [\(Fig. 1](#page-2-0)D,E). These data suggest that platelet TSP1 deficiency did not affect the development of diet-induced steatosis.

Platelet-specific TSP1 deficiency protected mice against dietinduced steatohepatitis

To determine whether platelet TSP1 deficiency affects the progression of simple steatosis to NASH, we conducted additional experiments over 32 weeks. We observed that AMLN-fed $TSP1^{APf4}$ mice exhibited reduced body weight and fat mass compared to control $TSP1^{F/F}$ mice [\(Fig. 2](#page-2-1)A,B). However, food intake and energy expenditure were similar between the two genotypes (data not shown). Interestingly, white fat tissue mass, including epididymal fat tissue (eWAT) and subcutaneous fat tissue (sWAT), was reduced in the AMLN-fed $TSP1^{APf4}$ mice (Figs S2A and S3A). Adipocyte size and distribution analysis showed that adipocytes from eWAT and sWAT of AMLN-fed $TSP1^{APf4}$ mice tended to be smaller than those of control $TSP1^{F/F}$ mice (Figs S2B and S3B). In addition, eWAT and sWAT from AMLN-fed TSP1^{4Pf4} mice exhibited increased expression of lipolysis-related genes (e.g. ATGL, LPL, and HSL) (Figs S2C and S3C). Platelet infiltration into eWAT and sWAT was comparable between control $TSP1^{F/F}$ and $TSP1^{APf4}$ mice, as shown by immunofluorescence staining (Figs S2D and S3D). Moreover, an in vitro study involving the coculturing of white preadipocytes (3T3-L1) with platelets isolated from WT or Tsp1 KO mice demonstrated that platelet-derived TSP1 did not significantly affect white pre-adipocyte proliferation (Fig. S4A). Interestingly, the co-culturing of Tsp1 KO platelets with 3T3-L1 cells seemed to stimulate their differentiation into adipocytes, as demonstrated by increased Oil Red O-positive staining and elevated expression of marker genes for differentiation, such as PPAR-r, AP2, etc. (Fig. S4B,C). These two findings, increased adipogenesis and an upregulated lipolysis pathway, appear paradoxical in the regulation of fat mass. However, the observed reduction in white fat mass in KO mice (TSP1 $\frac{APf4}{P}$) may depend on the relative rates of these opposing forces. In addition, the reduced expansion (hypertrophy) of adipocytes in KO mice may also contribute to the observed decrease in fat mass. This warrants further investigation in the future.

We also investigated the alteration of brown fat tissue (BAT) in two genotypes. We found that AMLN-fed $TSP1^{APf4}$ mice exhibited reduced BAT mass and whitening, as well as smaller size of brown adipocytes (Fig. S5A,B). BAT from AMLN-fed TSP1 4Pf4 mice showed increased expression of UCP1 and Nrg4 (neuregulin 4) (Fig. S5C), accompanied by reduced platelet accumulation in BAT (Fig. S5D). Nrg4 is a secreted protein enriched in BAT and has been shown to be involved in NAFLD/

NASH progression.^{34,[35](#page-10-6)} To further determine the effect of platelet-derived TSP1 on Nrg4 expression in brown adipocytes, a co-culture study was performed using a brown adipocyte cell line (T37i) and platelets. As shown in Fig. S5E, co-culturing of brown adipocytes with Tsp1 KO platelets resulted in increased Nrg4 expression and secretion compared to WT platelets. There was a trend towards an increase in plasma Nrg4 levels in TSP1^{4Pf4} mice compared to control $TSP1^{F/F}$ mice (Fig. S5F). These data suggest a role of TSP1-deficient platelets in regulating the endocrine function of BAT. Through secreted Nrg4 protein, BAT may communicate with the liver in AMLN-fed $TSP1^{APf4}$ mice, impacting NAFLD progression. Collectively, these data reveal a previously unrecognized role of platelet TSP1 in regulating white fat lipid metabolism and brown fat endocrine function. Whether these effects have a potential impact on NASH development in the current model remains to be determined.

Additionally, AMLN-fed $TSP1^{APf4}$ mice showed improved glucose homeostasis and lower plasma total cholesterol and LDL cholesterol [\(Fig. 2C](#page-2-1),D). Furthermore, in analyzing the blood profile, we observed an upregulation of white blood cells, particularly lymphocyte and monocyte populations, in AMLN-fed $TSP1^{F/F}$ mice, whereas a decrease in these cell counts was observed in AMLN-fed $TSP1^{APf4}$ mice (Table S3).

Furthermore, we analyzed liver phenotypes. As shown in [Fig. 3](#page-3-0)A, AMLN-fed TSP1^{Δ Pf4} mice exhibited less liver injury, as indicated by the reduced ALT levels. Liver weight/body weight ratio was reduced in AMLN-fed $TSP1^{APf4}$ mice, while liver triglycerides and total cholesterol were comparable between the two genotypes ([Fig. 3](#page-3-0)B,C). Histological analysis revealed decreased NAFLD scores, particularly inflammation, in AMLN-fed TSP1 4Pf4 mice ([Fig. 3D](#page-3-0)). The reduction in liver fibrosis in AMLNfed $TSP1^{APf4}$ mice was confirmed by Masson's trichrome and

Research article

Sirius Red staining, as well as qPCR ([Fig. 3E](#page-3-0),F). Reduced hepatic stellate cell activity was revealed by decreased levels of liver a-SMA protein [\(Fig. 3G](#page-3-0)). Taken together, these findings demonstrate that while platelet-derived TSP1 does not appear to influence the development of steatosis, it plays a significant role in the progression from steatosis to NASH and liver fibrosis.

Intrahepatic platelet accumulation, chemokine production and immune cell infiltration were attenuated in AMLN-fed TSP1 4Pf4 mice

The potential mechanisms underlying the protective effect of platelet-specific TSP1 deficiency on diet-induced NASH and liver fibrosis were investigated ([Fig. 3\)](#page-3-0). We found that liver $Tsp1$ mRNA levels were significantly reduced, and TSP1 protein levels trended towards a reduction in AMLN-fed TSP1 4Pf4 mice [\(Fig. 4\)](#page-4-0). Furthermore, we conducted whole-liver transcriptome analysis. In control $TSP1^{F/F}$ mice, a comparison of the AMLN and LF diets revealed a significant upregulation of 1,726 genes and a significant downregulation of 832 genes. When comparing AMLN-fed TSP1 F/F to the AMLN-fed TSP1 APf4 mice, there were 1,293 upregulated genes and 2,226 downregulated genes. We performed an enriched pathway analysis. As shown in [Fig. 5,](#page-5-0) KEGG-enriched pathway analysis revealed several specific downregulated pathways in $TSP1^{APf4}$ mice, including cytokine-cytokine receptor interaction and chemokine signaling pathways, among others. Consistently, gene ontology pathway analysis identified downregulated pathways related to negative regulation of the immune system process, tumor necrosis factor superfamily cytokine production, leukocyte cell-cell adhesion, leukocyte chemotaxis, cytokine or chemokine activity, and more. These findings are in line with the NAFLD score data ([Fig. 3D](#page-3-0)) and confirm the reduced liver inflammation observed in the AMLN-fed TSP1 APf4 mice. This further suggests that platelet Tsp1 deletion suppresses immune cell trafficking in the liver. As expected, the expression of chemokines such as CCL2, CXCL1, CXCL2, CXCL4 (PF4), and CXCL5 in the liver was reduced in AMLN-fed $TSP1^{APf4}$ mice compared to that in AMLN-fed $TSP1^{F/F}$ mice [\(Fig. 6](#page-6-0)A,B). This reduction was accompanied by decreased liver accumulation of immune cells such as neutrophils, CD4, and CD8 T cells in AMLN-fed TSP1^{APf4} mice ([Fig. 6C](#page-6-0),D).

We also conducted Reactome analysis of the liver RNA-seq data and identified that genes associated with platelet

activation, signaling, or aggregation (e.g., orm2, CD63, PF-4, plek, pik3r5) were upregulated in AMLN-fed TSP1^{F/F} livers but downregulated in AMLN-fed TSP1 APf4 livers ([Fig. 7A](#page-7-0),B). Additionally, we confirmed that platelet-rich or platelet-poor plasma isolated from AMLN-fed $TSP1^{APf4}$ mice exhibited reduced production of PF-4 (a chemotactic factor for neutrophils and monocytes 36) compared to AMLN-fed $TSP1^{F/F}$ mice ([Fig. 7C](#page-7-0)). Moreover, the results of liver immunohistochemical staining demonstrated a reduction in intrahepatic platelet accumulation and activation, as evidenced by decreased co-staining of CD41 and p-selectin (a marker for activated platelets) in AMLN-fed $TSP1^{APf4}$ mice ([Fig. 7D](#page-7-0),F). Reduced interaction between intrahepatic platelets and macrophages was also observed in AMLN-fed $TSP1^{APf4}$ mice ([Fig. 7E](#page-7-0)). Collectively, these findings suggest that TSP1-depleted platelets are less active and secrete fewer chemokines, which may contribute to reduced infiltration of immune cells in the liver.

TSP1-deficient platelets inhibited the development of inflammation and fibrosis in 3D human NASH organoids

To further validate the inhibitory effect of TSP1-deficient platelets on the development of NASH and demonstrate its relevance in a human context, we utilized a 3D human NASH in vitro model that was previously established in our studies.^{[29](#page-10-0)} In this model, human hepatocytes, macrophages, and stellate cells are cocultured to form scaffold-free 3D spheroids. WT or TSP1-

deficient platelets were added to 3D spheroids, which were then treated with NASH-inducing media for 3-5 days. After the treatment, cells were harvested for qPCR analysis. As shown in [Fig. 8](#page-8-0)A, the NASH media stimulated the expression of proinflammatory and profibrotic genes, such as IL-1 β , α -SMA, and TIMP1. However, the addition of TSP1-deficent platelets attenuated the upregulation of these genes, indicating a suppression of inflammation and fibrosis. Moreover, confocal fluorescence images demonstrated a reduction in α -SMA-positive staining in the 3D spheroids with TSP1-deficient platelets ([Fig. 8B](#page-8-0)). These results suggest that TSP1-deficient platelets have the potential to attenuate inflammation and fibrosis in NASH.

Discussion

In this study, we investigated the role of platelet- α granulederived TSP1 in the development and progression of NAFLD. To achieve this, we used both an AMLN diet-induced NASH mouse model and a 3D human NASH organoid model. Our findings demonstrate that deletion of TSP1 in platelets does not provide protection against obesity-associated steatosis in mice. However, it confers protection against obesity-associated NASH and liver fibrosis. Mechanistically, platelets lacking TSP1 exhibited reduced intrahepatic accumulation, activation, and chemokine secretion, resulting in decreased infiltration of immune cells into the liver and subsequently reduced stellate

Nuclei were stained with DAPI. Data are represented as mean ± SE (n = 5 mice/group); one-way ANOVA with Tukey's post hoc test. *p <0.05, **p <0.01, ***p <0.0001. LF, low fat.

cell activation. Collectively, these findings indicate that platelet-derived TSP1 plays a crucial role in the NAFLD progression and may serve as a potential therapeutic target for this disease.

TSP1 represents approximately 20% of the total protein in platelet a-granules, from where it is released upon platelet activation. As one of the most abundant α -granule proteins, platelet TSP1 has been shown to play a role in the regulation of thrombosis and hemostasis. Previous research has demonstrated that platelet-released TSP1 regulates platelet adhesion and collagen-dependent thrombosis stabilization through its

interaction with its receptor, CD36, in vitro.^{[37](#page-10-8)} TSP1 has also been shown to stimulate platelet aggregation by inhibiting the antithrombotic activity of nitric oxide/cGMP signaling 38 or contribute to von Willebrand factor-dependent thrombus formation.[39](#page-10-10) Additionally, recent research suggests that plateletderived TSP1 plays a role in promoting hemostasis and regulating thrombosis in vivo by modulating platelet cAMP signaling at sites of vascular injury. 40 However, it is important to note that these studies utilized global TSP1-deficient mice, which limits their ability to definitively determine the specific role of plateletderived TSP1 in hemostasis. In this study, we have generated

JHEP Reports

Fig. 8. Deletion of TSP1 in platelets attenuated inflammation and stellate cell activation in a human NASH organoid model. In vitro 3D human NASH model was established by co-culturing human hepatocyte/THP-1-derived macrophages/human stellate cells to form spheroids. Spheroids were treated with control media or NASH-inducing media for 5 days and then platelets were added from WT or Tsp1^{-/-} mice for an additional 5 days. (A) Gene expression was determined by qPCR; B) Representative immunofluorescent images from a spheroid (blue = DAPI; green = α SMA). Scale bar = 200 μ m; Data are represented as mean ± SE (n = 3 separate experiments); two-way ANOVA with Tukey's multiple comparisons test. *p <0.05; ***p <0.001. NASH, non-alcoholic steatohepatitis; WT, wild-type.

platelet-specific Tsp1 KO mice by crossbreeding TSP1-floxed mice with *pf4-cre* mice. The *pf4-cre* mouse model is a commonly used Cre driver for generating megakaryocyte/platelet-specific KO mice, although a more stringent megakaryocyte lineage-specific expression model, Gp1ba-Cre mice, has recently been developed by Nagy et al.^{[41](#page-10-12)} In our characterization of $TSP1^{4pf4}$ (8-week-old male mice), we did not observe any obvious abnormalities. Interestingly, $TSP1^{4pf4}$ mice exhibited normal blood platelet counts, platelet aggregation, and tail bleeding times compared to WT control mice. These findings suggest that platelet-derived TSP1 is not a significant contributor to hemostasis under physiological conditions, but further investigation is warranted to fully elucidate its role in hemostasis and thrombosis.

Our current study provides compelling evidence supporting the involvement of platelet-derived TSP1 in the regulation of diet-induced NASH development and progression. Previous studies from our lab and others have established the role of TSP1 in NAFLD/NASH.^{19,[20](#page-9-14),[23](#page-9-9)[,42,](#page-10-13)[43](#page-10-14)} This study takes a step further by advancing our understanding of the specific contribution of TSP1 derived from platelets to NAFLD progression. We found that platelet-derived TSP1 does not influence the development of diet-induced steatosis. In contrast, our findings suggest that in the late stages of NAFLD, activated platelets within the steatotic liver release TSP1 and other chemokines (e.g. CXCL1, CXCL2, and CXCL4) to attract immune cells (e.g. monocytes, neutrophils, and T cells) to infiltrate into the liver.^{[18](#page-9-8)[,36,](#page-10-7)[44](#page-10-15)} Recruitment of immune cells further amplifies proinflammatory signaling within the liver, leading to stellate cell activation and the subsequent development of liver fibrosis. Consistent with the in vivo study, a 3D human NASH in vitro model further demonstrated that TSP1 deficient platelets have the potential to attenuate inflammation and fibrosis directly or indirectly through secreted factors to affect liver cell functions. These findings open new avenues for potential platelet-based therapy in NASH, particularly

considering the minimal impact of TSP1-deficient platelets on hemostasis.

It is known that anucleate platelets cannot be directly modified using traditional genetic approaches. Instead, hematopoietic stem cell-derived megakaryocytes, the nucle-ated precursor to platelets, can be genetically manipulated.^{[45](#page-10-16)} Hematopoietic stem cells can be isolated from bone marrow, peripheral blood, and cord blood after birth. Furthermore, recent studies have demonstrated the efficient differentiation of blood CD34+ hematopoietic progenitors into megakaryocytes.[46](#page-10-17) Additionally, CRISPR/Cas9 transfection can perform efficient gene editing in CD34+ cells.^{[47](#page-10-18)} These exciting recent advances in human platelet functional studies are truly promising, making it possible for us to target TSP1 in platelets for therapeutic purposes. This could be achieved by isolating CD34+ hematopoietic stem cells from patient blood, performing in vitro CRISPR-mediated TSP1 deletion, differentiating these cells into mature megakaryocytes, and producing TSP1 depleted platelets. Subsequently, these gene-modified platelets could be transfused back into the same patient for therapeutic purposes.

Additionally, our current study has unveiled a previously unknown role of platelet-derived TSP1 in regulating brown fat endocrine/paracrine function. Brown fat has been recognized as a source of various molecules known as batokines, including IL-6, FGF21, and Nrg4, which possess the ability to communicate with other organs, influencing systemic metabolism.^{[48](#page-10-19)} Among the batokines analyzed in our study, we found that Nrg4 expression was notably upregulated in brown fat from $TSP1^{4pf4}$ mice. In vitro studies further demonstrated a negative regulatory effect of platelet-derived TSP1 on Nrg4 production in brown adipocytes. Nrg4 is known to establish a link between brown fat and the liver. Interestingly, previous research has demonstrated the crucial role of hepatic Nrg4 signaling in the

progression from steatosis to NASH. 34 This finding raises the intriguing possibility that the protective effect of TSP1-deficient platelets on NASH progression could also be partially mediated by the crosstalk between brown fat and the liver. However, this relationship warrants further investigation in future studies. Our discovery of this potential novel interaction between platelet-derived TSP1, Nrg4, brown fat, and the liver may add a new layer of complexity to our understanding of NASH progression. Unraveling the interplay between these factors may

Abreviations

lead to new therapeutic approaches for NASH and related metabolic disorders.

In summary, our study utilizing tissue-specific Tsp1 KO mice offers compelling evidence linking platelet-derived TSP1 to the pathogenesis of NAFLD/NASH progression. This novel finding sheds light on the intricate interplay between platelet function, obesity, and liver disease. Importantly, our findings suggest that platelet-derived TSP1 holds promise as a potential therapeutic target for managing NAFLD/NASH.
