DISCUSSION .....	17
AUTHORS' CONCLUSIONS .....	19
ACKNOWLEDGEMENTS .....	20
REFERENCES .....	21
CHARACTERISTICS OF STUDIES .....	29
DATA AND ANALYSES .....	82
Analysis 1.1. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 1 Perinatal mortality. ....	87
Analysis 1.2. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 2 Preterm birth less than 34 weeks. ....	88
Analysis 1.3. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 3 Preterm birth less than 37 weeks. ....	88
Analysis 1.4. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 4 Threatened preterm labour. ....	89
Analysis 1.5. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 5 Spontaneous vaginal delivery. ....	90
Analysis 1.6. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 6 Caesarean section. ....	90
Analysis 1.7. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 7 Antenatal corticosteroids. ....	91
Analysis 1.8. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 8 Antenatal tocolysis. ....	91
Analysis 1.9. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 9 Infant birthweight less than 2500 g. ....	92
Analysis 1.10. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 10 Respiratory distress syndrome. ....	93
Analysis 1.11. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 11 Use of assisted ventilation. ....	93
Analysis 1.12. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 12 Intraventricular haemorrhage - all grades. ....	94
Analysis 1.13. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 13 Intraventricular haemorrhage - grade III or IV. ....	95
Analysis 1.14. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 14 Periventricular leucomalacia. ....	95
Analysis 1.15. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 15 Retinopathy of prematurity. ....	96
Analysis 1.16. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 16 Necrotising enterocolitis. ....	96
Analysis 1.17. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 17 Neonatal sepsis. ....	97
Analysis 1.18. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 18 Patent ductus arteriosus. ....	97
Analysis 1.19. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 19 Intrauterine fetal death. ....	98

Analysis 1.20. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 20 Neonatal death. ....	98
Analysis 1.21. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 21 Developmental delay. ....	99
Analysis 1.22. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 22 Intellectual impairment. ....	99
Analysis 1.23. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 23 Motor Impairment. ....	100
Analysis 1.24. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 24 Visual Impairment. ....	100
Analysis 1.25. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 25 Hearing Impairment. ....	100
Analysis 1.26. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 26 Cerebral palsy. ....	101
Analysis 1.27. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 27 Learning difficulties. ....	101
Analysis 1.28. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 28 Height less than 5th centile. ....	102
Analysis 1.29. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 29 Weight less than 5th centile. ....	102
Analysis 1.30. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 30 Adverse drug reaction. ....	102
Analysis 1.31. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 31 Pregnancy prolongation (weeks). ....	103
Analysis 1.32. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 32 Apgar score < 7. ....	103
Analysis 1.33. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 33 Admission to neonatal intensive care unit. ....	104
Analysis 1.34. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 34 Neonatal length of hospital stay (days). ....	104
Analysis 1.35. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 35 Infant weight at 6 months follow-up (g). ....	104
Analysis 1.36. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 36 Infant weight at 12 months follow-up (g). ....	105
Analysis 1.37. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 37 Infant weight at 24 months follow-up (g). ....	105
Analysis 1.38. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 38 Infant length at 6 months follow-up (cm). ....	106
Analysis 1.39. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 39 Infant length at 12 months follow-up (cm). ....	106
Analysis 1.40. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 40 Infant length at 24 months follow-up (cm). ....	106
Analysis 1.41. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 41 Infant head circumference at 6 months follow-up (cm). ....	107
Analysis 1.42. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 42 Infant head circumference at 12 months follow-up (cm). ....	107
Analysis 1.43. Comparison 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth (singletons), Outcome 43 Infant head circumference at 24 months follow-up (cm). ....	107
Analysis 2.1. Comparison 2 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth, by timing of commencement (< 20 wk v > 20 wk, singletons), Outcome 1 Preterm birth less than 37 weeks. ....	108
Analysis 3.1. Comparison 3 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth by cumulative weekly dose (< 500 mg v >= 500 mg, singletons), Outcome 1 Perinatal death. ....	110
Analysis 3.2. Comparison 3 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth by cumulative weekly dose (< 500 mg v >= 500 mg, singletons), Outcome 2 Preterm birth less than 37 weeks. ....	111
Analysis 3.3. Comparison 3 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth by cumulative weekly dose (< 500 mg v >= 500 mg, singletons), Outcome 3 Threatened preterm labour. ....	111

Analysis 3.4. Comparison 3 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth by cumulative weekly dose (< 500 mg v >= 500 mg, singletons), Outcome 4 Caesarean section. ....	112
Analysis 3.5. Comparison 3 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth by cumulative weekly dose (< 500 mg v >= 500 mg, singletons), Outcome 5 Antenatal corticosteroids. ....	113
Analysis 3.6. Comparison 3 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth by cumulative weekly dose (< 500 mg v >= 500 mg, singletons), Outcome 6 Need for tocolysis. ....	113
Analysis 3.7. Comparison 3 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth by cumulative weekly dose (< 500 mg v >= 500 mg, singletons), Outcome 7 Respiratory distress syndrome. ....	114
Analysis 3.8. Comparison 3 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth by cumulative weekly dose (< 500 mg v >= 500 mg, singletons), Outcome 8 Intraventricular haemorrhage - all grades. ....	114
Analysis 3.9. Comparison 3 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth by cumulative weekly dose (< 500 mg v >= 500 mg, singletons), Outcome 9 Intraventricular haemorrhage - grade III or IV. ....	115
Analysis 3.10. Comparison 3 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth by cumulative weekly dose (< 500 mg v >= 500 mg, singletons), Outcome 10 Necrotising enterocolitis. ....	115
Analysis 3.11. Comparison 3 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth by cumulative weekly dose (< 500 mg v >= 500 mg, singletons), Outcome 11 Intrauterine fetal death. ....	116
Analysis 3.12. Comparison 3 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth by cumulative weekly dose (< 500 mg v >= 500 mg, singletons), Outcome 12 Neonatal death. ....	116
Analysis 4.1. Comparison 4 Progesterone versus placebo: ultrasound identified short cervix, singletons, Outcome 1 Perinatal death. ....	120
Analysis 4.2. Comparison 4 Progesterone versus placebo: ultrasound identified short cervix, singletons, Outcome 2 Preterm birth less than 34 weeks. ....	120
Analysis 4.3. Comparison 4 Progesterone versus placebo: ultrasound identified short cervix, singletons, Outcome 3 Preterm labour. ....	121
Analysis 4.4. Comparison 4 Progesterone versus placebo: ultrasound identified short cervix, singletons, Outcome 4 Prelabour spontaneous rupture of membranes. ....	121
Analysis 4.5. Comparison 4 Progesterone versus placebo: ultrasound identified short cervix, singletons, Outcome 5 Side effects (any). ....	122
Analysis 4.6. Comparison 4 Progesterone versus placebo: ultrasound identified short cervix, singletons, Outcome 6 Side effects (injection site). ....	122
Analysis 4.7. Comparison 4 Progesterone versus placebo: ultrasound identified short cervix, singletons, Outcome 7 Side effects (urticaria). ....	123
Analysis 4.8. Comparison 4 Progesterone versus placebo: ultrasound identified short cervix, singletons, Outcome 8 Side effects (nausea). ....	123
Analysis 4.9. Comparison 4 Progesterone versus placebo: ultrasound identified short cervix, singletons, Outcome 9 Pregnancy prolongation (days). ....	123
Analysis 4.10. Comparison 4 Progesterone versus placebo: ultrasound identified short cervix, singletons, Outcome 10 Caesarean section. ....	124
Analysis 4.11. Comparison 4 Progesterone versus placebo: ultrasound identified short cervix, singletons, Outcome 11 Antenatal tocolysis. ....	124
Analysis 4.12. Comparison 4 Progesterone versus placebo: ultrasound identified short cervix, singletons, Outcome 12 Preterm birth less than 37 weeks. ....	125
Analysis 4.13. Comparison 4 Progesterone versus placebo: ultrasound identified short cervix, singletons, Outcome 13 Preterm birth less than 28 weeks. ....	125
Analysis 4.14. Comparison 4 Progesterone versus placebo: ultrasound identified short cervix, singletons, Outcome 14 Infant birthweight less than 2500 g. ....	126
Analysis 4.15. Comparison 4 Progesterone versus placebo: ultrasound identified short cervix, singletons, Outcome 15 Respiratory distress syndrome. ....	126
Analysis 4.16. Comparison 4 Progesterone versus placebo: ultrasound identified short cervix, singletons, Outcome 16 Apgar score < 7. ....	127
Analysis 4.17. Comparison 4 Progesterone versus placebo: ultrasound identified short cervix, singletons, Outcome 17 Need for assisted ventilation. ....	127
Analysis 4.18. Comparison 4 Progesterone versus placebo: ultrasound identified short cervix, singletons, Outcome 18 Intraventricular haemorrhage - all grades. ....	128
Analysis 4.19. Comparison 4 Progesterone versus placebo: ultrasound identified short cervix, singletons, Outcome 19 Intraventricular haemorrhage - grades III or IV. ....	128

Analysis 4.20. Comparison 4 Progesterone versus placebo: ultrasound identified short cervix, singletons, Outcome 20 Periventricular leucomalacia. ....	129
Analysis 4.21. Comparison 4 Progesterone versus placebo: ultrasound identified short cervix, singletons, Outcome 21 Retinopathy of prematurity. ....	129
Analysis 4.22. Comparison 4 Progesterone versus placebo: ultrasound identified short cervix, singletons, Outcome 22 Necrotising enterocolitis. ....	130
Analysis 4.23. Comparison 4 Progesterone versus placebo: ultrasound identified short cervix, singletons, Outcome 23 Neonatal sepsis. ....	130
Analysis 4.24. Comparison 4 Progesterone versus placebo: ultrasound identified short cervix, singletons, Outcome 24 Intrauterine fetal death. ....	131
Analysis 4.25. Comparison 4 Progesterone versus placebo: ultrasound identified short cervix, singletons, Outcome 25 Neonatal death. ....	131
Analysis 4.26. Comparison 4 Progesterone versus placebo: ultrasound identified short cervix, singletons, Outcome 26 Admission to neonatal intensive care unit. ....	132
Analysis 5.1. Comparison 5 Progesterone versus placebo: ultrasound identified short cervix, singletons by cumulative weekly dose (<500 mg v >=500 mg), Outcome 1 Periventricular leucomalacia. ....	133
Analysis 5.2. Comparison 5 Progesterone versus placebo: ultrasound identified short cervix, singletons by cumulative weekly dose (<500 mg v >=500 mg), Outcome 2 Admission to neonatal intensive care unit. ....	133
Analysis 6.1. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 1 Perinatal death. ....	139
Analysis 6.2. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 2 Preterm birth less than 34 weeks. ...	140
Analysis 6.3. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 3 Preterm PROM. ....	140
Analysis 6.4. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 4 Adverse drug reaction. ....	141
Analysis 6.5. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 5 Caesarean section. ....	141
Analysis 6.6. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 6 Spontaneous birth. ....	142
Analysis 6.7. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 7 Assisted birth. ....	142
Analysis 6.8. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 8 Satisfaction with therapy. ....	143
Analysis 6.9. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 9 Antenatal tocolysis. ....	143
Analysis 6.10. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 10 Antenatal corticosteroids. ....	144
Analysis 6.11. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 11 Preterm birth less than 37 weeks. ....	144
Analysis 6.12. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 12 Preterm birth less than 28 weeks. ....	145
Analysis 6.13. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 13 Infant birthweight less than 2500 g. ....	146
Analysis 6.14. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 14 Apgar score < 7 at 5 minutes. ....	146
Analysis 6.15. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 15 Respiratory distress syndrome. ..	147
Analysis 6.16. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 16 Use of assisted ventilation. ....	148
Analysis 6.17. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 17 Intraventricular haemorrhage - grades III or IV. ....	148
Analysis 6.18. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 18 Intraventricular haemorrhage - all grades. ....	149
Analysis 6.19. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 19 Periventricular leucomalacia. ....	149
Analysis 6.20. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 20 Retinopathy of prematurity. ....	150
Analysis 6.21. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 21 Chronic lung disease. ....	150
Analysis 6.22. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 22 Necrotising enterocolitis. ....	151
Analysis 6.23. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 23 Neonatal sepsis. ....	151
Analysis 6.24. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 24 Fetal death. ....	152
Analysis 6.25. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 25 Neonatal death. ....	152
Analysis 6.26. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 26 Admission to NICU. ....	153
Analysis 6.27. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 27 Perinatal death. ....	154
Analysis 6.28. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 28 Preterm birth less than 34 weeks. ....	154
Analysis 6.29. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 29 Preterm PROM. ....	155
Analysis 6.30. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 30 Caesarean section. ....	155
Analysis 6.31. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 31 Antenatal tocolysis. ....	156
Analysis 6.32. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 32 Antenatal corticosteroids. ....	157
Analysis 6.33. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 33 Preterm birth less than 37 weeks. ....	157

Analysis 6.34. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 34 Preterm birth less than 28 weeks.	158
Analysis 6.35. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 35 Infant birthweight less than 2500 g.	158
Analysis 6.36. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 36 Apgar score < 7 at 5 minutes.	159
Analysis 6.37. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 37 Use of assisted ventilation.	160
Analysis 6.38. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 38 Fetal death.	160
Analysis 6.39. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 39 Neonatal death.	161
Analysis 6.40. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 40 Admission to NICU.	161
Analysis 6.41. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 41 Sensitivity analysis for perinatal death (assuming total non-independence).	162
Analysis 6.42. Comparison 6 Progesterone versus placebo: multiple pregnancy, Outcome 42 Sensitivity analysis for perinatal death (assuming 1% non-independence).	163
Analysis 7.1. Comparison 7 Progesterone versus placebo: multiple pregnancy, by timing of commencement (< 20 wk v > 20 wk), Outcome 1 Preterm birth < 37 weeks.	164
Analysis 7.2. Comparison 7 Progesterone versus placebo: multiple pregnancy, by timing of commencement (< 20 wk v > 20 wk), Outcome 2 Neonatal death.	164
Analysis 7.3. Comparison 7 Progesterone versus placebo: multiple pregnancy, by timing of commencement (< 20 wk v > 20 wk), Outcome 3 Admission to NICU.	165
Analysis 8.1. Comparison 8 Progesterone versus placebo: multiple pregnancy by cumulative weekly dose (< 500 mg v >= 500 mg), Outcome 1 Perinatal death.	167
Analysis 8.2. Comparison 8 Progesterone versus placebo: multiple pregnancy by cumulative weekly dose (< 500 mg v >= 500 mg), Outcome 2 Preterm birth less than 34 weeks.	167
Analysis 8.3. Comparison 8 Progesterone versus placebo: multiple pregnancy by cumulative weekly dose (< 500 mg v >= 500 mg), Outcome 3 Antenatal tocolysis.	168
Analysis 8.4. Comparison 8 Progesterone versus placebo: multiple pregnancy by cumulative weekly dose (< 500 mg v >= 500 mg), Outcome 4 Preterm birth less than 37 weeks.	169
Analysis 8.5. Comparison 8 Progesterone versus placebo: multiple pregnancy by cumulative weekly dose (< 500 mg v >= 500 mg), Outcome 5 Infant birthweight less than 2500 g.	169
Analysis 8.6. Comparison 8 Progesterone versus placebo: multiple pregnancy by cumulative weekly dose (< 500 mg v >= 500 mg), Outcome 6 Respiratory distress syndrome.	170
Analysis 8.7. Comparison 8 Progesterone versus placebo: multiple pregnancy by cumulative weekly dose (< 500 mg v >= 500 mg), Outcome 7 Fetal death.	171
Analysis 8.8. Comparison 8 Progesterone versus placebo: multiple pregnancy by cumulative weekly dose (< 500 mg v >= 500 mg), Outcome 8 Admission to NICU.	171
Analysis 9.1. Comparison 9 Progesterone versus placebo/no treatment: prior threatened preterm labour, singletons, Outcome 1 Perinatal death.	174
Analysis 9.2. Comparison 9 Progesterone versus placebo/no treatment: prior threatened preterm labour, singletons, Outcome 2 Preterm birth less than 34 weeks' gestation.	175
Analysis 9.3. Comparison 9 Progesterone versus placebo/no treatment: prior threatened preterm labour, singletons, Outcome 3 Pregnancy prolongation (days).	175
Analysis 9.4. Comparison 9 Progesterone versus placebo/no treatment: prior threatened preterm labour, singletons, Outcome 4 Pregnancy prolongation - less than 1 week.	176
Analysis 9.5. Comparison 9 Progesterone versus placebo/no treatment: prior threatened preterm labour, singletons, Outcome 5 Pregnancy prolongation - 1.0 to 1.9 weeks.	176
Analysis 9.6. Comparison 9 Progesterone versus placebo/no treatment: prior threatened preterm labour, singletons, Outcome 6 Pregnancy prolongation - 2 weeks or more.	177
Analysis 9.7. Comparison 9 Progesterone versus placebo/no treatment: prior threatened preterm labour, singletons, Outcome 7 Spontaneous birth.	177
Analysis 9.8. Comparison 9 Progesterone versus placebo/no treatment: prior threatened preterm labour, singletons, Outcome 8 Caesarean section.	177
Analysis 9.9. Comparison 9 Progesterone versus placebo/no treatment: prior threatened preterm labour, singletons, Outcome 9 Use of tocolysis.	178
Analysis 9.10. Comparison 9 Progesterone versus placebo/no treatment: prior threatened preterm labour, singletons, Outcome 10 Preterm birth less than 37 weeks' gestation.	178
Analysis 9.11. Comparison 9 Progesterone versus placebo/no treatment: prior threatened preterm labour, singletons, Outcome 11 Infant birthweight less than 2500 g.	179

Analysis 9.12. Comparison 9 Progesterone versus placebo/no treatment: prior threatened preterm labour, singletons, Outcome 12 Respiratory distress syndrome. ....	179
Analysis 9.13. Comparison 9 Progesterone versus placebo/no treatment: prior threatened preterm labour, singletons, Outcome 13 Intraventricular haemorrhage grade III or IV. ....	180
Analysis 9.14. Comparison 9 Progesterone versus placebo/no treatment: prior threatened preterm labour, singletons, Outcome 14 Periventricular leucomalacia. ....	180
Analysis 9.15. Comparison 9 Progesterone versus placebo/no treatment: prior threatened preterm labour, singletons, Outcome 15 Use of assisted ventilation. ....	181
Analysis 9.16. Comparison 9 Progesterone versus placebo/no treatment: prior threatened preterm labour, singletons, Outcome 16 Necrotizing enterocolitis. ....	181
Analysis 9.17. Comparison 9 Progesterone versus placebo/no treatment: prior threatened preterm labour, singletons, Outcome 17 Neonatal sepsis. ....	181
Analysis 9.18. Comparison 9 Progesterone versus placebo/no treatment: prior threatened preterm labour, singletons, Outcome 18 Fetal death. ....	182
Analysis 9.19. Comparison 9 Progesterone versus placebo/no treatment: prior threatened preterm labour, singletons, Outcome 19 Neonatal death. ....	182
Analysis 9.20. Comparison 9 Progesterone versus placebo/no treatment: prior threatened preterm labour, singletons, Outcome 20 Neonatal length of hospital stay (days). ....	183
Analysis 9.21. Comparison 9 Progesterone versus placebo/no treatment: prior threatened preterm labour, singletons, Outcome 21 Apgar score less than seven at five minutes. ....	183
Analysis 9.22. Comparison 9 Progesterone versus placebo/no treatment: prior threatened preterm labour, singletons, Outcome 22 Prelabour spontaneous rupture of membranes. ....	184
Analysis 9.23. Comparison 9 Progesterone versus placebo/no treatment: prior threatened preterm labour, singletons, Outcome 23 Preterm birth less than 28 weeks' gestation. ....	184
Analysis 9.24. Comparison 9 Progesterone versus placebo/no treatment: prior threatened preterm labour, singletons, Outcome 24 Apgar score less than seven at five minutes. ....	184
Analysis 9.25. Comparison 9 Progesterone versus placebo/no treatment: prior threatened preterm labour, singletons, Outcome 25 Admission to neonatal intensive care unit. ....	185
Analysis 10.1. Comparison 10 Progesterone versus placebo/no treatment: prior threatened preterm labour, singletons, by cumulative weekly dose (< 500 mg v >= 500 mg), Outcome 1 Pregnancy prolongation (days). ....	186
Analysis 10.2. Comparison 10 Progesterone versus placebo/no treatment: prior threatened preterm labour, singletons, by cumulative weekly dose (< 500 mg v >= 500 mg), Outcome 2 Preterm birth less than 37 weeks' gestation. ....	186
Analysis 10.3. Comparison 10 Progesterone versus placebo/no treatment: prior threatened preterm labour, singletons, by cumulative weekly dose (< 500 mg v >= 500 mg), Outcome 3 Respiratory distress syndrome. ....	187
Analysis 10.4. Comparison 10 Progesterone versus placebo/no treatment: prior threatened preterm labour, singletons, by cumulative weekly dose (< 500 mg v >= 500 mg), Outcome 4 Neonatal sepsis. ....	188
Analysis 10.5. Comparison 10 Progesterone versus placebo/no treatment: prior threatened preterm labour, singletons, by cumulative weekly dose (< 500 mg v >= 500 mg), Outcome 5 Neonatal death. ....	188
Analysis 11.1. Comparison 11 Progesterone versus placebo: other reason at risk of preterm birth, singletons, Outcome 1 Perinatal death. ....	189
Analysis 11.2. Comparison 11 Progesterone versus placebo: other reason at risk of preterm birth, singletons, Outcome 2 Preterm birth less than 34 weeks. ....	190
Analysis 11.3. Comparison 11 Progesterone versus placebo: other reason at risk of preterm birth, singletons, Outcome 3 Preterm birth less than 37 weeks. ....	190
Analysis 11.4. Comparison 11 Progesterone versus placebo: other reason at risk of preterm birth, singletons, Outcome 4 Infant birthweight less than 2500 g. ....	191
Analysis 11.5. Comparison 11 Progesterone versus placebo: other reason at risk of preterm birth, singletons, Outcome 5 Intrauterine fetal death. ....	192
Analysis 11.6. Comparison 11 Progesterone versus placebo: other reason at risk of preterm birth, singletons, Outcome 6 Neonatal death. ....	192
Analysis 11.7. Comparison 11 Progesterone versus placebo: other reason at risk of preterm birth, singletons, Outcome 7 Admission to neonatal intensive care unit. ....	192
Analysis 12.1. Comparison 12 Progesterone versus placebo: other reason at risk of preterm birth, by timing of commencement (< 20 wk v > 20 wk, singletons), Outcome 1 Perinatal death. ....	193
Analysis 12.2. Comparison 12 Progesterone versus placebo: other reason at risk of preterm birth, by timing of commencement (< 20 wk v > 20 wk, singletons), Outcome 2 Preterm birth less than 37 weeks. ....	194

---

Analysis 12.3. Comparison 12 Progesterone versus placebo: other reason at risk of preterm birth, by timing of commencement (< 20 wk v > 20 wk, singletons), Outcome 3 Infant birthweight less than 2500 g. ....	195

## ABSTRACT

### Background

Preterm birth is a major complication of pregnancy associated with perinatal mortality and morbidity. Progesterone for the prevention of preterm labour has been advocated.

### Objectives

To assess the benefits and harms of progesterone for the prevention of preterm birth for women considered to be at increased risk of preterm birth and their infants.

### Search methods

We searched the Cochrane Pregnancy and Childbirth Group's Trials Register (14 January 2013) and reviewed the reference list of all articles.

### Selection criteria

Randomised controlled trials, in which progesterone was given for preventing preterm birth.

### Data collection and analysis

Two review authors independently evaluated trials for methodological quality and extracted data.

### Main results

Thirty-six randomised controlled trials (8523 women and 12,515 infants) were included.

### Progesterone versus placebo for women with a past history of spontaneous preterm birth

Progesterone was associated with a statistically significant reduction in the risk of perinatal mortality (six studies; 1453 women; risk ratio (RR) 0.50, 95% confidence interval (CI) 0.33 to 0.75), preterm birth less than 34 weeks (five studies; 602 women; average RR 0.31, 95% CI 0.14 to 0.69), infant birthweight less than 2500 g (four studies; 692 infants; RR 0.58, 95% CI 0.42 to 0.79), use of assisted ventilation

(three studies; 633 women; RR 0.40, 95% CI 0.18 to 0.90), necrotising enterocolitis (three studies; 1170 women; RR 0.30, 95% CI 0.10 to 0.89), neonatal death (six studies; 1453 women; RR 0.45, 95% CI 0.27 to 0.76), admission to neonatal intensive care unit (three studies; 389 women; RR 0.24, 95% CI 0.14 to 0.40), preterm birth less than 37 weeks (10 studies; 1750 women; average RR 0.55, 95% CI 0.42 to 0.74) and a statistically significant increase in pregnancy prolongation in weeks (one study; 148 women; mean difference (MD) 4.47, 95% CI 2.15 to 6.79). No differential effects in terms of route of administration, time of commencing therapy and dose of progesterone were observed for the majority of outcomes examined.

#### **Progesterone versus placebo for women with a short cervix identified on ultrasound**

Progesterone was associated with a statistically significant reduction in the risk of preterm birth less than 34 weeks (two studies; 438 women; RR 0.64, 95% CI 0.45 to 0.90), preterm birth at less than 28 weeks' gestation (two studies; 1115 women; RR 0.59, 95% CI 0.37 to 0.93) and increased risk of urticaria in women when compared with placebo (one study; 654 women; RR 5.03, 95% CI 1.11 to 22.78). It was not possible to assess the effect of route of progesterone administration, gestational age at commencing therapy, or total cumulative dose of medication.

#### **Progesterone versus placebo for women with a multiple pregnancy**

Progesterone was associated with no statistically significant differences for the reported outcomes.

#### **Progesterone versus no treatment/placebo for women following presentation with threatened preterm labour**

Progesterone, was associated with a statistically significant reduction in the risk of infant birthweight less than 2500 g (one study; 70 infants; RR 0.52, 95% CI 0.28 to 0.98).

#### **Progesterone versus placebo for women with 'other' risk factors for preterm birth**

Progesterone, was associated with a statistically significant reduction in the risk of infant birthweight less than 2500 g (three studies; 482 infants; RR 0.48, 95% CI 0.25 to 0.91).

#### **Authors' conclusions**

The use of progesterone is associated with benefits in infant health following administration in women considered to be at increased risk of preterm birth due either to a prior preterm birth or where a short cervix has been identified on ultrasound examination. However, there is limited information available relating to longer-term infant and childhood outcomes, the assessment of which remains a priority.

Further trials are required to assess the optimal timing, mode of administration and dose of administration of progesterone therapy when given to women considered to be at increased risk of early birth.

### **PLAIN LANGUAGE SUMMARY**

#### **Prenatal administration of progesterone to prevent preterm birth in women considered to be at risk of having their baby early**

Babies who are born before 37 weeks, and particularly those born before 34 weeks, are at greater risk of having problems at birth and complications in infancy. Infants who are born preterm are at greater risk of dying in their first year of life, and of those infants who survive, there is an increased risk of repeated admission to hospital and adverse outcomes including cerebral palsy and long-term disability. Progesterone is a hormone that reduces contractions of the uterus and has an important role in maintaining pregnancy and is suggested for the prevention of preterm labour. Maternal side-effects from progesterone therapy include headache, breast tenderness, nausea, cough and local irritation if administered intramuscularly. At present, there is little information available regarding the optimal dose of progesterone, mode of administration, gestation to commence therapy, or duration of therapy.

The review of 36 randomised controlled trials, involving a total of 8523 women considered to be at increased risk of preterm birth, and 12,515 infants, found that where progesterone was given (by injection into the muscle in some studies and as a pessary into the vagina in others), it had beneficial effects, including reducing the risk of the baby dying after birth, suffering complications such as requiring assisted ventilation, necrotising enterocolitis or requiring admission to neonatal intensive care, prolonging the pregnancy, and reducing the chance of neonatal intensive care admission.

Information related to longer-term infant and childhood outcomes was limited. Overall, the trials included in this review were considered to be of good to fair quality. Further trials are required to assess the optimal timing, mode of administration and dose of administration of progesterone therapy.

## BACKGROUND

### Description of the condition

Preterm birth before 37 weeks' gestation is a common problem in obstetric care, with estimates ranging from 5% in several European countries to 18% in some African countries (Blencowe 2012). In Australia, approximately 8% of all infants were born preterm in 2000, with 2.7% of these births occurring prior to 34 weeks' gestation (AIHW 2003). Figures are similar for the United States, with a preterm birth rate of 12.0% (Blencowe 2012). While less than 2% of these infants were born prior to 32 weeks' gestation (Martin 2003), they are at increased risk of complications in infancy, and contribute in excess of 50% of the overall perinatal mortality (AIHW 2003). Infants who are born preterm are at greater risk of dying in their first year of life (Martin 2003), and of those infants who survive, there is an increased risk of repeated admission to hospital (Elder 1999) and adverse outcomes including cerebral palsy and long-term disability (Hack 1999; Stanley 1992), creating a significant burden upon the community (Kramer 2000).

The 'cause' of preterm labour is multifactorial in origin, and it is important to consider the role of any identifiable risk factors in a woman's pregnancy.

The most significant and consistently identified risk factor for preterm birth, is a woman's history of previous preterm birth (Adams 2000; Bakketeig 1979; Berkowitz 1993; Bloom 2001; Goldenberg 1998; Kaminski 1973; Kistka 2007; Papiernik 1974; Petrini 2005; Robinson 2001). Estimates suggest the rate of recurrent preterm birth in this group of women to be 22.5% (Petrini 2005), a 2.5 times increased risk ratio when compared with women with no previous spontaneous preterm birth (Mercer 1999). For women with a history of a single preterm birth, the recurrence risk in a subsequent pregnancy is approximately 15%, increasing to 32% where there have been two previous preterm births (Carr-Hill 1985). Information derived from population-based cohort data suggests that for women who give birth between 20 and 31 weeks' gestation in one pregnancy, 29.3% will give birth prior to 37 weeks in a subsequent pregnancy (Adams 2000). For approximately 10% of these women, the preterm birth will occur at a similar gestational age (Adams 2000; Kistka 2007). In up to 50% of cases of preterm birth, the cause is spontaneous onset of labour or preterm premature rupture of membranes (PPROM) (Hewitt 1988; Mattison 2001; McLaughlin 2002).

Other characteristics in a woman's current pregnancy may place her at increased risk of preterm birth, including women with a short cervix identified by ultrasound assessment, the presence of fetal fibronectin in the vaginal secretions, and presentation with symptoms or signs of threatened preterm labour.

The identification of a short cervix (considered to be less than 2.5cm) on ultrasound examination has been associated with an increased likelihood of preterm birth before 34 weeks' gestation (Smith 2007). Identification of fetal fibronectin present in cervico-vaginal secretions has also been proposed as a means of identifying women at risk of preterm birth. Overall, the value of fetal fibronectin in women presenting with symptoms of threatened preterm labour, is a negative test, where women are unlikely to proceed to preterm birth before 34 weeks' gestation or within seven days of testing (Smith 2007).

Multiple pregnancy is a strong risk factor for preterm birth though the mechanisms may be different to those operating in women with a singleton pregnancy. Up to 50% of women with a twin pregnancy will give birth prior to 37 weeks' gestation (AIHW 2003). The preterm birth risk of early birth before 37 weeks for women with a singleton pregnancy is 6.3% compared with 97% for women with a triplet pregnancy (AIHW 2003).

### Description of the intervention

Progesterone may be administered in various forms and by various routes. These different formulations and modes of administration will have different absorption patterns and potentially have differing bio effects. Whilst no teratogenic effects have been described with most progesterones, there is little in the way of long-term safety data. Maternal side-effects from progesterone therapy include headache, breast tenderness, nausea, cough and local irritation if administered intramuscularly. At present, there is little information available regarding the optimal dose of progesterone, mode of administration, gestation to commence therapy, or duration of therapy (Greene 2003; Iams 2003).

### How the intervention might work

Progesterone has a role in maintaining pregnancy (Haluska 1997; Pepe 1995; Pieber 2001) and is thought to act by suppressing smooth muscle activity in the uterus (Astle 2003; Grazzini 1998). In many animal species, there is a reduction in the amount of circulating progesterone before the onset of labour. While these changes have not been shown to occur in women (Astle 2003; Block 1984; Lopez-Bernal 2003; Pieber 2001; Smit 1984), it has been suggested that there is a 'functional' withdrawal of progesterone related to changes in the expression of progesterone receptors in the uterus (Astle 2003; Condon 2003; Haluska 2002; Pieber 2001). There have been recent reports in the literature advocating the use of progesterone to reduce the risk of preterm birth (da Fonseca 2003; Meis 2003), rekindling interest that dates back to the 1960s (Le Vine 1964).

This review was modified in 2006, from the original protocol published in *The Cochrane Library* in Issue 4, 2004, in order to clarify the scope of the review. The title and objectives changed, and the description of participants expanded to include the reason the women were considered to be at increased risk of preterm birth. The primary outcome measure of preterm birth less than 32 weeks' gestation has been changed to preterm birth less than 34 weeks' gestation to be consistent with World Health Organization definitions of preterm birth. Secondary outcome measures reflecting childhood developmental assessment have been added, reflecting the need for ongoing evaluation of children participating in randomised trials.

### Why it is important to do this review

Preterm birth and its consequences for women and their babies is a significant health problem in pregnancy and childbirth. While the suppression or prevention of preterm labour should lead to improved survival through a lower incidence of premature delivery, there are theoretical reasons why a fetus may not survive without disability. It is possible that an intrauterine mechanism that would trigger preterm labour could also cause neurological injury to the fetus and that progesterone may prevent labour but not fetal injury. The purpose of this review is to assess the benefits and harms of progesterone administration for the prevention of preterm birth for

both women and their infants, when considering the risk factors present for preterm birth.

## OBJECTIVES

To assess the benefits and harms of progesterone administration for the prevention of preterm birth in women and their infants.

## METHODS

### Criteria for considering studies for this review

#### Types of studies

All published and unpublished randomised controlled trials, in which progesterone was administered for the prevention of preterm birth, subdivided by the reason women were considered to be at risk for preterm birth.

Trials were excluded if:

- they utilised quasi-randomised methodology; cross-over design;
- progesterone was administered for the acute treatment of actual or threatened preterm labour (that is, where progesterone was administered as an acute tocolytic medication); or
- progesterone was administered in the first trimester only for preventing miscarriage.

#### Types of participants

Pregnant women considered to be at increased risk of preterm birth. These reasons include:

- past history of spontaneous preterm birth (including preterm prelabour rupture of membranes);
- multiple pregnancy;
- ultrasound identified short cervical length;
- fetal fibronectin testing;
- following acute presentation with symptoms or signs of threatened preterm labour (where a tocolytic medication may have been administered);
- other reason considered to be at increased risk of preterm birth.

#### Types of interventions

Administration of progesterone by any route for the prevention of preterm birth.

#### Types of outcome measures

##### Primary outcomes

1. Perinatal mortality
2. Preterm birth (less than 34 weeks' gestation)
3. Major neurodevelopmental handicap at childhood follow-up

##### Secondary outcomes

###### Maternal

1. Threatened preterm labour (as defined by trial authors)
2. Prelabour spontaneous rupture of membranes
3. Adverse drug reaction

4. Pregnancy prolongation (interval between randomisation and birth)
5. Mode of birth
6. Number of antenatal hospital admissions
7. Satisfaction with the therapy
8. Use of tocolysis
9. Antenatal corticosteroids (not a prespecified outcome)
10. Maternal quality of life (not a prespecified outcome)

###### Infant

1. Birth before 37 completed weeks
2. Birth before 28 completed weeks
3. Birthweight less than the third centile for gestational age
4. Birthweight less than 2500 g
5. Apgar score of less than seven at five minutes
6. Respiratory distress syndrome
7. Use of mechanical ventilation
8. Duration of mechanical ventilation
9. Intraventricular haemorrhage - grades III or IV
10. Periventricular leucomalacia
11. Retinopathy of prematurity
12. Retinopathy of prematurity - grades III or IV
13. Chronic lung disease
14. Necrotising enterocolitis
15. Neonatal sepsis
16. Fetal death
17. Neonatal death
18. Admission to neonatal intensive care unit
19. Neonatal length of hospital stay
20. Teratogenic effects (including virilisation in female infants)
21. Patent ductus arteriosus (not a prespecified outcome)

###### Child

1. Major sensorineural disability (defined as any of legal blindness, sensorineural deafness requiring hearing aids, moderate or severe cerebral palsy, or developmental delay or intellectual impairment (defined as developmental quotient or intelligence quotient less than -2 standard deviations below mean))
2. Developmental delay (however defined by the authors)
3. Intellectual impairment
4. Motor impairment
5. Visual impairment
6. Blindness
7. Deafness
8. Hearing impairment
9. Cerebral palsy
10. Child behaviour
11. Child temperament
12. Learning difficulties
13. Growth assessments at childhood follow-up (weight, head circumference, length, skin fold thickness)

## Search methods for identification of studies

### Electronic searches

We searched the Cochrane Pregnancy and Childbirth Group's Trials Register by contacting the Trials Search Co-ordinator (14 January 2013).

The Cochrane Pregnancy and Childbirth Group's Trials Register is maintained by the Trials Search Co-ordinator and contains trials identified from:

1. monthly searches of the Cochrane Central Register of Controlled Trials (CENTRAL);
2. weekly searches of MEDLINE;
3. weekly searches of Embase;
4. handsearches of 30 journals and the proceedings of major conferences;
5. weekly current awareness alerts for a further 44 journals plus monthly BioMed Central email alerts.

Details of the search strategies for CENTRAL, MEDLINE and Embase, the list of handsearched journals and conference proceedings, and the list of journals reviewed via the current awareness service can be found in the 'Specialized Register' section within the editorial information about the [Cochrane Pregnancy and Childbirth Group](#).

Trials identified through the searching activities described above are each assigned to a review topic (or topics). The Trials Search Co-ordinator searches the register for each review using the topic list rather than keywords.

For details of searching carried out for the initial version of the review, please see [Appendix 1](#).

### Searching other resources

We also manually cross-referenced key publications.

We did not apply any language restrictions.

### Data collection and analysis

For the methods used when assessing the trials identified in the previous version of this review, see [Appendix 2](#).

For this update we used the following methods when assessing the reports identified by the updated search.

### Selection of studies

Two review authors independently assessed for inclusion all the potential studies identified as a result of the search strategy. We resolved any disagreement through discussion or, if required, we consulted a third author.

### Data extraction and management

We designed a form to extract data. For eligible studies, two review authors extracted the data using the agreed form. We resolved discrepancies through discussion or, if required, we consulted third author. We entered data into Review Manager software ([RevMan 2012](#)) and checked for accuracy. When information regarding any of the above was unclear, we contacted authors of the original reports to provide further details.

## Assessment of risk of bias in included studies

Two review authors independently assessed the risk of bias for each study using the criteria outlined in the *Cochrane Handbook for Systematic Reviews of Interventions* ([Higgins 2011](#)). Disagreement was resolved by discussion or by involving the third author.

### (1) Sequence generation (checking for possible selection bias)

We described for each included study the method used to generate the allocation sequence in sufficient detail to allow an assessment of whether it should produce comparable groups.

We assessed the method as:

- low risk of bias (any truly random process, e.g. random number table; computer random number generator);
- high risk of bias (any non-random process, e.g. odd or even date of birth; hospital or clinic record number);
- unclear risk of bias.

### (2) Allocation concealment (checking for possible selection bias)

We described for each included study the method used to conceal allocation to interventions prior to assignment and assessed whether intervention allocation could have been foreseen in advance of, or during recruitment, or changed after assignment.

We assessed the methods as:

- low risk of bias (e.g. telephone or central randomisation; consecutively numbered sealed opaque envelopes);
- high risk of bias (open random allocation; unsealed or non-opaque envelopes, alternation; date of birth);
- unclear risk of bias.

### (3.1) Blinding of participants and personnel (checking for possible performance bias)

We described for each included study the methods used, if any, to blind study participants and personnel from knowledge of which intervention a participant received. We considered that studies were at low risk of bias if they were blinded, or if we judged that the lack of blinding would be unlikely to affect results. We planned to assess blinding separately for different outcomes or classes of outcomes.

We assessed the methods as:

- low, high or unclear risk of bias for participants;
- low, high or unclear risk of bias for personnel.

### (3.2) Blinding of outcome assessment (checking for possible detection bias)

We described for each included study the methods used, if any, to blind outcome assessors from knowledge of which intervention a participant received. We planned to assess blinding separately for different outcomes or classes of outcomes.

We assessed methods used to blind outcome assessment as:

- low, high or unclear risk of bias.

#### **(4) Incomplete outcome data (checking for possible attrition bias due to the amount, nature and handling of incomplete outcome data)**

We described for each included study, and for each outcome or class of outcomes, the completeness of data including attrition and exclusions from the analysis. We stated whether attrition and exclusions were reported and the numbers included in the analysis at each stage (compared with the total randomised participants), reasons for attrition or exclusion where reported, and whether missing data were balanced across groups or were related to outcomes. Where sufficient information was reported, or could be supplied by the trial authors, we planned to re-include missing data in the analyses which we undertook.

We assessed methods as:

- low risk of bias (e.g. no missing outcome data; missing outcome data balanced across groups; or less than 20% losses to follow-up);
- high risk of bias (e.g. numbers or reasons for missing data imbalanced across groups; ‘as treated’ analysis done with substantial departure of intervention received from that assigned at randomisation);
- unclear risk of bias.

#### **(5) Selective reporting bias**

We described for each included study how we investigated the possibility of selective outcome reporting bias and what we found. We assessed the methods as:

- low risk of bias (where it is clear that all of the study’s pre-specified outcomes and all expected outcomes of interest to the review have been reported);
- high risk of bias (where not all the study’s pre-specified outcomes have been reported; one or more reported primary outcomes were not prespecified; outcomes of interest are reported incompletely and so cannot be used; study fails to include results of a key outcome that would have been expected to have been reported);
- unclear risk of bias.

#### **(6) Other sources of bias (checking for bias due to problems not covered by (1) to (5) above)**

We described for each included study any important concerns we had about other possible sources of bias.

We assessed whether studies that included multiple pregnancies accounted appropriately for non-independence of babies from the same pregnancy in the analysis. There are several ways this can be done, and these studies should present something like an odds ratio adjusted for non-independence. If adjustment was not done, we assessed the potential for bias i.e. if multiples only made up a small proportion of the total then there is probably not much potential for bias.

We assessed whether each study was free of other problems that could put it at risk of bias:

- low risk of other bias;
- high risk of other bias;
- unclear whether there is risk of other bias.

#### **(7) Overall risk of bias**

We made explicit judgements about whether studies were at high risk of bias, according to the criteria given in the *Cochrane Handbook* (Higgins 2011). With reference to (1) to (6) above, we assessed the likely magnitude and direction of the bias and whether we considered it likely to impact on the findings. We planned to explore the impact of the level of bias through undertaking sensitivity analyses - see [Sensitivity analysis](#).

#### **Measures of treatment effect**

##### **Dichotomous data**

For dichotomous data, we presented results as summary risk ratio with 95% confidence intervals.

##### **Continuous data**

For continuous data, we used the mean difference if outcomes were measured in the same way between trials. We planned to use the standardised mean difference to combine trials that measured the same outcome, but used different methods, if required.

#### **Unit of analysis issues**

##### **Cluster-randomised trials**

We did not identify any cluster-randomised trials for inclusion in this review, but we may include trials of this type in future updates. If we do, we plan to include cluster-randomised trials in the analyses along with individually-randomised trials. Their sample sizes will be adjusted using the methods described in the *Cochrane Handbook* (Higgins 2011) using an estimate of the intracluster correlation co-efficient (ICC) derived from the trial (if possible), or from another source. If ICCs from other sources are used, we will report this and conduct sensitivity analyses to investigate the effect of variation in the ICC. If we identify both cluster-randomised trials and individually-randomised trials, we planned to synthesise the relevant information. We consider it reasonable to combine the results from both if there is little heterogeneity between the study designs and the interaction between the effect of intervention and the choice of randomisation unit is considered to be unlikely. We also planned to acknowledge heterogeneity in the randomisation unit and perform a sensitivity analysis to investigate the effects of the randomisation unit.

##### **Cross-over trials**

Cross-over trials were not included.

##### **Other unit of analysis issues**

The analysis in this review involves multiple pregnancies, therefore, wherever possible, analyses should be adjusted for clustering to take into account the non-independence of babies from the same pregnancy (Gates 2004). Treating babies from multiple pregnancies as if they are independent, when they are more likely to have similar outcomes than babies from different pregnancies, will overestimate the sample size and give confidence intervals that are too narrow. Each woman can be considered a cluster in multiple pregnancy, with the number of individuals in the cluster being equal to the number of fetuses in her pregnancy. Analysis using cluster trial methods allows calculation of relative risk and adjustment of confidence intervals. Usually this will mean that the confidence intervals get wider. Although this may make little

difference to the conclusion of a trial, it avoids misleading results in those trials where the difference may be substantial.

We planned to adjust for clustering in the analyses, wherever possible, and to use the inverse variance method for adjusted analyses, as described in the *Cochrane Handbook for Systematic Reviews of Interventions* (Higgins 2011). However, due to insufficient information in the included trials, we were not able to adjust our analyses. In future updates, if possible, we will adjust for clustering in the analyses.

### Dealing with missing data

For included studies, we noted levels of attrition. We explored the impact of including studies with high levels of missing data in the overall assessment of treatment effect by using sensitivity analysis. For all outcomes, we carried out analyses, as far as possible, on an intention-to-treat basis, i.e. we attempted to include all participants randomised to each group in the analyses, and all participants were analysed in the group to which they were allocated, regardless of whether or not they received the allocated intervention. The denominator for each outcome in each trial was the number randomised minus any participants whose outcomes were known to be missing.

### Assessment of heterogeneity

We assessed statistical heterogeneity in each meta-analysis using the  $T^2$ ,  $I^2$  and  $\text{Chi}^2$  statistics. We regarded heterogeneity as substantial if an  $I^2$  was greater than 30% and either the  $T^2$  was greater than zero, or there was a low P value (less than 0.10) in the  $\text{Chi}^2$  test for heterogeneity.

### Assessment of reporting biases

If 10 or more studies contributed data to meta-analysis for any particular outcome, we investigated reporting biases (such as publication bias) using funnel plots. We assessed possible asymmetry visually. If asymmetry was suggested by a visual assessment, we planned to perform exploratory analyses to investigate it. In this version of the review insufficient data were available to allow us to carry out this planned analysis.

### Data synthesis

We carried out statistical analysis using the RevMan software (RevMan 2012). We used fixed-effect meta-analysis for combining data where it was reasonable to assume that studies were estimating the same underlying treatment effect: i.e. where trials examined the same intervention, and where we judged the trials' populations and methods to be sufficiently similar. If we suspected clinical heterogeneity sufficient to expect the underlying treatment effects to differ between trials, or if substantial statistical heterogeneity was detected, we used random-effects meta-analysis to produce an overall summary provided that we considered an average treatment effect across trials was clinically meaningful. The random-effects summary was treated as the average of the range of possible treatment effects and the clinical implications of treatment effects differing between trials is discussed. If the average treatment effect was not clinically meaningful we did not combine trials.

Where we used random-effects analyses, the results were presented as the average treatment effect with 95% confidence intervals, and the estimates of  $T^2$  and  $I^2$ .

Results were analysed according to the reason women were considered to be at risk of preterm birth, including:

- past history of spontaneous preterm birth (including preterm prelabour rupture of membranes);
- multiple pregnancy;
- ultrasound identified short cervical length;
- fetal fibronectin testing;
- presentation with symptoms or signs of threatened preterm labour;
- other reason for risk of preterm birth.

For analyses where there are high levels of heterogeneity we have provided an estimate of the 95% range of underlying intervention effects (prediction interval).

### Subgroup analysis and investigation of heterogeneity

If we identified substantial heterogeneity, we investigated it using subgroup analyses and sensitivity analyses. We considered whether an overall summary was meaningful, and if it was, we used random-effects analysis to produce it.

We planned, where possible, to carry out the following subgroup analyses:

1. time of treatment commencing (before 20 weeks' gestation versus after 20 weeks' gestation);
2. route of administration (intramuscular, intravaginal, oral, intravenous);
3. different dosage regimens (divided arbitrarily into a cumulative dose of less than 500 mg per week and a dose of greater than or equal to 500 mg per week).

All outcomes were considered in subgroup analyses.

We assessed subgroup differences by interaction tests available within RevMan (RevMan 2012).

### Sensitivity analysis

We planned to carry out sensitivity analyses to explore the effect of trial quality assessed by concealment of allocation, high attrition rates (greater than 20%), or both, with poor-quality studies being excluded from the analyses in order to assess whether this made any difference to the overall result.

## RESULTS

### Description of studies

#### Results of the search

In the 2006 update, our search strategy identified 22 studies for consideration. Eleven studies met the inclusion criteria stated (Borna 2008; da Fonseca 2003; Facchinetti 2007; Fonseca 2007; Hartikainen 1980; Hauth 1983; Johnson 1975; Meis 2003; O'Brien 2007; Papiernik 1970; Rouse 2007) involving a total of 2714 women and 3452 infants. The study by Northern (Northern 2007) reports the follow-up of children involved in the Meis study (Meis 2003).

Sixty-four reports from an updated search in January 2013 have been assessed for this update. Of these 64 reports, an additional 25 studies (33 reports) to the original 11 studies, were included

(Aboulghar 2012; Akbari 2009; Briery 2011; Caritis 2009; Cetingoz 2011; Combs 2010; Combs 2011; Combs 2011a; Elsheikhah 2010; Glover 2011; Grobman 2012; Hassan 2011; Ibrahim 2010; Lim 2011; Majhi 2009; Moghtadaei 2008; Ndoni 2010; Norman 2009; Rai 2009; Rode 2011; Rozenberg 2012; Saghafi 2011a; Senat 2012; Serra 2013; Sharami 2010); seven studies (seven reports) were excluded (Abbott 2012; Arikani 2011; Berghella 2010; Chandiramani 2012; Ionescu 2012; Keeler 2009; Rust 2006); two studies (two reports) are ongoing studies (Coomarasamy 2012; van Os 2011); one is an additional report of an ongoing study (Crowther 2007); one additional report was added to each of the following included studies (Combs 2010; Combs 2011; Facchinetti 2007; Lim 2011; Nassar 2007). Two additional reports were identified for the Norman 2009; O'Brien 2007; Rode 2011 and Rouse 2007 included studies. Three additional reports were identified for the Meis 2003 included study.

A total of 36 studies are included in this update.

### Included studies

Refer to table [Characteristics of included studies](#) for further details.

#### *Use of progesterone in women with a history of prior spontaneous preterm birth*

##### Description of studies

Eleven studies were included involving a total of 1936 women with a past history of spontaneous preterm birth (Akbari 2009; Cetingoz 2011; da Fonseca 2003; Glover 2011; Johnson 1975; Ibrahim 2010; Majhi 2009; Meis 2003; O'Brien 2007; Rai 2009; Saghafi 2011a). Four studies compared weekly intramuscular injection with placebo (Ibrahim 2010; Johnson 1975; Meis 2003) or routine care (Saghafi 2011a); five studies compared daily vaginal progesterone, three with placebo (Cetingoz 2011; da Fonseca 2003; O'Brien 2007) and two with routine care (Akbari 2009; Majhi 2009); and two studies compared daily oral progesterone with placebo (Glover 2011; Rai 2009). Dose of progesterone administered varied from 90 mg daily (O'Brien 2007), to 100 mg daily (Akbari 2009; Cetingoz 2011; da Fonseca 2003; Majhi 2009), to 200 mg daily (Rai 2009), to 400 mg daily (Glover 2011), to 200 mg weekly (Rai 2009), to 250 mg weekly (Johnson 1975; Meis 2003; Saghafi 2011a). Supplementation commenced prior to 20 weeks' gestation in four trials (Glover 2011; Johnson 1975; Meis 2003; O'Brien 2007), and continued up to a gestational age varying from 24 weeks (Johnson 1975; Majhi 2009; Rai 2009), to 28 weeks (da Fonseca 2003), to 34 weeks (Akbari 2009; Cetingoz 2011), to 36 weeks (Ibrahim 2010; Meis 2003), and to 37 weeks (O'Brien 2007; Saghafi 2011a) gestation.

The primary outcomes reported by the trials related to the occurrence of preterm birth prior to 28 weeks' gestation (Rai 2009), 32 weeks' gestation (O'Brien 2007), 34 weeks' gestation (Akbari 2009; Majhi 2009), and 37 weeks' gestation (Akbari 2009; Cetingoz 2011; da Fonseca 2003; Ibrahim 2010; Johnson 1975; Majhi 2009; Meis 2003; Saghafi 2011a). Eight trials involved single centres (Akbari 2009; da Fonseca 2003; Glover 2011; Ibrahim 2010; Johnson 1975; Majhi 2009; Rai 2009; Saghafi 2011a), and two were multicentre trials (Meis 2003; O'Brien 2007), conducted principally from the United States of America (Glover 2011; Johnson 1975; Meis 2003; O'Brien 2007), India (Majhi 2009; Rai 2009), Iran (Akbari 2009; Saghafi 2011a), Egypt (Ibrahim 2010), Istanbul (Cetingoz 2011), and Brazil (da Fonseca 2003). The report by Northen 2007 reports childhood follow-up of 348 participants in the Meis randomised trial (Meis 2003).

One study (Cetingoz 2011) included a mix of women with a history of prior preterm birth (n = 71) and women with a multiple pregnancy (n = 67) and the results for this study have been analysed separately for the two risk groups.

#### *Use of progesterone in women with a short cervix identified on transvaginal ultrasound examination*

##### Description of studies

Four studies were included involving 1560 women who were identified with a short cervix (various definitions: less than 15 mm (Fonseca 2007); less than 30 mm (Grobman 2012); between 10 and 20mm (Hassan 2011); and less than 25 mm (Rozenberg 2012)) at the time of transvaginal ultrasound examination. One study compared weekly intramuscular injection with placebo (Grobman 2012); one study compared twice weekly intramuscular injection with no treatment (Rozenberg 2012) and two studies compared daily intravaginal progesterone with placebo (Fonseca 2007; Hassan 2011). Dose of progesterone administered varied from 90 mg daily in the morning (Hassan 2011), to 200 mg nightly (Fonseca 2007), to 250 mg weekly (Grobman 2012), to 500 mg twice weekly (Rozenberg 2012). Supplementation commenced from 16 to 22 weeks' gestation in one study (Grobman 2012), from 19 to 23 weeks in another study (Hassan 2011), from 24 to 31 weeks in another study (Rozenberg 2012), and from 24 to 33 completed weeks of gestation in another study (Fonseca 2007).

The primary outcomes reported by the trials related to the occurrence of preterm birth prior to 33 weeks' gestation (Hassan 2011), 34 weeks' gestation (Fonseca 2007), 35 weeks' gestation (Grobman 2012), or 37 weeks' gestation (Grobman 2012) and time from randomisation to delivery in one study (Rozenberg 2012). All trials were multicentre conducted in centres worldwide, including the United Kingdom, USA, France, Greece, Chile and Brazil.

One study (Fonseca 2007) included a mix of singleton and twin pregnancies (226 singleton and 24 twin pregnancies), but due to the small proportion of twin pregnancies in this study, we have analysed all of this data within the short cervix subgroup.

#### *Use of progesterone in women with a multiple pregnancy*

##### Description of studies

Fourteen studies were included involving 3792 women; 11 trials with a twin pregnancy (Aboulghar 2012; Cetingoz 2011; Combs 2011; Elsheikhah 2010; Fonseca 2007; Hartikainen 1980; Norman 2009; Rode 2011; Rouse 2007; Senat 2012; Serra 2013), two trials with a triplet pregnancy (Caritis 2009; Combs 2010) or one trial with any multiple pregnancy, e.g. twins, triplets or quadruplets (Lim 2011). Six studies compared 250 mg weekly intramuscular progesterone injections with placebo (Caritis 2009; Combs 2010; Combs 2011; Hartikainen 1980; Lim 2011; Rouse 2007); one study compared 1000 mg weekly intramuscular progesterone injections with no treatment (Senat 2012); three studies compared intravaginal progesterone with placebo (Aboulghar 2012; Cetingoz 2011; Elsheikhah 2010), one at a daily dose of 100 mg (Cetingoz 2011), one at a daily dose of 200 mg (Elsheikhah 2010) and one at a daily dose of 400 mg (Aboulghar 2012); one study compared 90 mg daily intravaginal gel with placebo (Norman 2009); and one study compared 100 mg daily oral progesterone with placebo (Rode 2011). One trial (Serra 2013) consisted of three groups and compared 200 mg daily intravaginal progesterone with 400 mg daily intravaginal progesterone with placebo. Supplementation

commenced from 16 to 20 weeks' gestation in three studies (Caritis 2009; Lim 2011; Rouse 2007), from 16 to 22 weeks in one study (Combs 2010), from 16 to 24 weeks in one study (Combs 2011), from 18 to 24 weeks in one study (Aboulghar 2012; Rode 2011), from 24 to 34 weeks in two studies (Cetingoz 2011; Elsheikhah 2010), from 24 weeks' gestation in one study (Norman 2009), and from 28 completed weeks' of gestation in one study (Hartikainen 1980).

The primary outcomes reported by the trials related to the occurrence of preterm birth prior to 34 weeks' gestation (Aboulghar 2012; Cetingoz 2011; Rode 2011; Senat 2012) or 37 weeks' gestation (Aboulghar 2012; Cetingoz 2011; Serra 2013), delivery or fetal loss before 34 weeks' gestation (Norman 2009), delivery or fetal loss before 35 weeks' gestation (Caritis 2009), mean cervical length and mean gestational age at delivery (Elsheikhah 2010), perinatal death (Hartikainen 1980) or composite neonatal morbidity (Combs 2010; Combs 2011; Lim 2011; Senat 2012). Five trials were multicentre conducted in centres worldwide, including the United Kingdom, USA, the Netherlands, Denmark, Austria and France (Caritis 2009; Combs 2010; Combs 2011; Lim 2011; Norman 2009; Rode 2011; Rouse 2007) and four were single-centre trials conducted in Istanbul, Egypt and Finland (Aboulghar 2012; Cetingoz 2011; Elsheikhah 2010; Hartikainen 1980).

Two studies included a mix of women with multiple and singleton pregnancies (Aboulghar 2012; Cetingoz 2011). One study (Aboulghar 2012) included a mix of women with singleton pregnancies (n = 215) and women with a multiple pregnancy (n = 91) all conceived by IVF/ICSI (in vitro fertilisation/intracytoplasmic sperm injection) and the results for this study have been analysed separately for the two risk groups: women at risk of preterm birth for 'other' reasons; and women with a multiple pregnancy. One study (Cetingoz 2011) included a mix of women with a history of prior preterm birth (n = 71) and women with a multiple pregnancy (n = 67) and the results for this study have been analysed separately for the two risk groups.

### **Use of progesterone in women following symptoms or signs of threatened preterm labour**

#### **Description of studies**

Six small studies were included involving a total of 505 women presenting with symptoms or signs of threatened preterm labour (Borna 2008; Briery 2011; Combs 2011a; Facchinetti 2007; Ndoni 2010; Sharami 2010). Two studies compared 250 mg weekly progesterone injections with placebo (Briery 2011; Combs 2011a), one study compared vaginal progesterone pessaries on a daily basis (400 mg) with no treatment (Borna 2008), one study compared 341 mg intramuscular progesterone injection every four days with no treatment (Facchinetti 2007), one study had three arms and compared intramuscular progesterone with oral progesterone with placebo (Ndoni 2010) and one study compared vaginal pessaries on a daily basis (200 mg) with placebo pessaries (Sharami 2010). Women presented with symptoms and signs between 24 and 34 weeks' gestation (Borna 2008), between 25 and 33 weeks' gestation (Facchinetti 2007), between 20 and 30 weeks' gestation (Briery 2011), between 23 and 31.9 weeks' gestation (Combs 2011a), between 15 and 22 weeks' gestation (Ndoni 2010) and between 28 and 36 weeks' gestation (Sharami 2010). The primary outcomes reported included the interval from randomisation to birth in one study (Borna 2008), transvaginal ultrasound assessment of cervical length in one study (Facchinetti 2007), gestational age at birth in

one study (Briery 2011), prolongation of pregnancy and composite neonatal morbidity in one study (Combs 2011a) and time until delivery and birth before 34 or 37 completed weeks in one study (Sharami 2010). In one study, reported only in abstract form, data relating to outcomes was not reported (Ndoni 2010). One study was a multicentre study conducted in the USA (Combs 2011a) and the remaining five studies were single-centre studies conducted in Iran, the USA, Italy, and Albania (Borna 2008; Briery 2011; Facchinetti 2007; Ndoni 2010; Sharami 2010).

### **Use of progesterone in women at risk of preterm birth for 'other' reasons**

#### **Description of studies**

Papiernik 1970 recruited 99 women from Paris, France, in a single centred trial, with a 'high preterm risk score'. Women were allocated to receive intramuscular progesterone three times per week or placebo, from 28 to 32 weeks' gestation.

Hauth 1983 involved 168 women from the United States of America who were considered to be at risk of preterm birth due to active military service. Women received 1000 mg of progesterone weekly or placebo, from 16 to 20 weeks' gestation, up until 36 weeks' gestation. The primary outcome for the study related to the incidence of preterm birth at less than 37 weeks' gestation.

Moghtadaei 2008 involved 260 women from Iran, in a single centre trial, who were considered to be at risk of preterm birth due to advanced maternal age (greater than 35 years). Women received weekly injections of 17P (250 mg) starting at 16 to 20 weeks' gestation until 34 weeks or matching placebo. The main outcomes for the study included delivery before 37, 35 or 32 weeks' gestation, hypertension, diabetes, intrauterine growth restriction or side effects at the injection site. Data from this study could not be included in a meta-analysis because the number of women randomised to each group was not reported in the brief abstract report of the study.

Aboulghar 2012 recruited 313 women from Egypt who were considered to be at high risk of preterm birth because all the pregnancies were conceived by IVF or ICSI. Women received vaginal progesterone 200 mg twice daily from randomisation until delivery or 37 weeks' gestation or matching placebo. The primary outcomes included preterm birth of singleton and twin pregnancies before 37 completed weeks and before 34 completed weeks. This study contains a mix of singleton pregnancies (n = 215) and twin pregnancies (n = 91) and presented some outcome data separately, as well as for the whole group. The results for this study have been analysed separately for the two risk groups: multiple pregnancies and women at risk for 'other' reasons.

#### **Excluded studies**

In total, 16 studies were excluded (Abbott 2012; Arikian 2011; Berghella 2010; Breart 1979; Brenner 1962; Chandiramani 2012; Corrado 2002; Hobel 1986; Ionescu 2012; Keeler 2009; Le Vine 1964; Rust 2006; Suvonnakote 1986; Turner 1966; Walch 2005; Yemini 1985). Three studies were excluded as they used a quasi-randomised method of treatment allocation (Le Vine 1964; Suvonnakote 1986; Yemini 1985). One study (Hobel 1986) compared an oral progestogen with placebo, but presented outcomes only as percentages. Five studies were excluded as progesterone was administered in the first trimester to prevent miscarriage (Breart

1979; Brenner 1962; Corrado 2002; Turner 1966; Walch 2005), and are covered by the Cochrane review relating to the use of progesterone for prevention of miscarriage (Haas 2008). One study was excluded because progesterone was administered as an acute tocolytic medication (Arikan 2011). A further six studies were excluded because they compared progesterone with cerclage (Abbott 2012; Chandiramani 2012; Ionescu 2012; Keeler 2009; Rust 2006) or compared cerclage with no cerclage (Berghella 2010), and are covered by other Cochrane reviews (Alfirevic 2012; Rafael 2011).

Refer to table [Characteristics of excluded studies](#) for further details.

**Studies awaiting assessment**

There are 11 ongoing studies awaiting assessment (Coomarasamy 2012; Creasy 2008; Crowther 2007; Martinez 2007; Nassar 2007; Norman 2012; Perlitz 2007; Starkey 2008; Swaby 2007; van Os 2011; Wood 2007).

**Risk of bias in included studies**

The overall quality of the included trials varied from good to fair. Refer to table [Characteristics of included studies](#) for further details and to [Figure 1](#); [Figure 2](#), for a summary of 'Risk of bias' assessments.

**Figure 1. 'Risk of bias' graph: review authors' judgements about each risk of bias item presented as percentages across all included studies.**

**Figure 2. 'Risk of bias' summary: review authors' judgements about each risk of bias item for each included study.**

	Random sequence generation (selection bias)	Allocation concealment (selection bias)	Incomplete outcome data (attrition bias)	Selective reporting (reporting bias)	Other bias	Blinding of participants and personnel (performance bias)	Blinding of outcome assessment (detection bias)

**Allocation**

While all trials were stated to be randomised and placebo controlled, the method of randomisation was only described in 23 trials (Borna 2008; Briery 2011; Caritis 2009; Cetingoz 2011; Combs 2010; Combs 2011; Combs 2011a; da Fonseca 2003; Facchinetti 2007; Glover 2011; Grobman 2012; Hassan 2011; Lim 2011; Majhi 2009; Meis 2003; Norman 2009; O'Brien 2007; Rai 2009; Rode 2011; Rouse 2007; Rozenberg 2012; Senat 2012; Serra 2013). Allocation concealment was assessed as low risk of bias in 23 trials (Aboulghar 2012; Briery 2011; Caritis 2009; Cetingoz 2011; Combs 2010; Combs 2011; Combs 2011a; da Fonseca 2003; Fonseca 2007; Glover 2011; Grobman 2012; Hassan 2011; Johnson 1975; Lim 2011; Majhi 2009; Meis 2003; Norman 2009; O'Brien 2007; Rai 2009; Rode 2011; Rouse 2007; Senat 2012; Serra 2013); and unclear in 13 trials (Akbari 2009; Borna 2008; Elsheikhah 2010; Facchinetti 2007; Hartikainen 1980; Hauth 1983; Ibrahim 2010; Moghtadaei 2008; Ndoni 2010; Papiernik 1970; Rozenberg 2012; Saghafi 2011a; Sharami 2010).

**Blinding**

Twenty-five of the 32 included trials were placebo controlled, with blinding of caregivers and participants (Aboulghar 2012; Briery 2011; Caritis 2009; Cetingoz 2011; Combs 2010; Combs 2011; Combs 2011a; da Fonseca 2003; Fonseca 2007; Glover 2011; Grobman 2012; Hartikainen 1980; Hassan 2011; Hauth 1983; Johnson 1975; Lim 2011; Meis 2003; Norman 2009; O'Brien 2007; Papiernik 1970; Rai 2009; Rode 2011; Rouse 2007; Serra 2013; Sharami 2010).

Blinding of outcome assessment was evident in 15 of the trials (Aboulghar 2012; Combs 2010; da Fonseca 2003; Fonseca 2007; Grobman 2012; Hartikainen 1980; Hauth 1983; Johnson 1975; Lim 2011; Meis 2003; O'Brien 2007; Papiernik 1970; Rode 2011; Rouse 2007; Serra 2013).

Four trials were assessed as high risk of bias for both blinding of caregivers and participants and outcome assessment as no blinding was attempted (Borna 2008; Facchinetti 2007; Rozenberg 2012; Senat 2012).

**Incomplete outcome data**

Thirty-one studies were assessed as being at low risk of bias for attrition bias. Thirteen studies reported no losses to follow-up (Borna 2008; Caritis 2009; Combs 2010; Combs 2011a; Facchinetti 2007; Fonseca 2007; Hartikainen 1980; Hauth 1983; Ibrahim 2010; Majhi 2009; Meis 2003; Papiernik 1970; Saghafi 2011a) and 18 studies reported less than 20% loss to follow-up (Aboulghar 2012; Briery 2011; Cetingoz 2011; Combs 2011; da Fonseca 2003; Glover 2011; Grobman 2012; Hassan 2011; Johnson 1975; Lim 2011; Norman 2009; O'Brien 2007; Rai 2009; Rode 2011; Rouse 2007; Rozenberg 2012; Serra 2013; Sharami 2010). In five studies reported only in abstract form, it was unclear whether attrition bias was present (Elsheikhah 2010; Grobman 2012; Moghtadaei 2008; Ndoni 2010; Senat 2012) and in one study details were insufficient to make a judgement (Akbari 2009).

## Selective reporting

Twenty-five studies were assessed as being at low risk of bias for selective reporting (Aboulghar 2012; Akbari 2009; Borna 2008; Caritis 2009; Cetingoz 2011; Combs 2010; Combs 2011; Combs 2011a; da Fonseca 2003; Fonseca 2007; Grobman 2012; Hartikainen 1980; Hassan 2011; Hauth 1983; Ibrahim 2010; Johnson 1975; Lim 2011; Majhi 2009; Meis 2003; Norman 2009; O'Brien 2007; Rai 2009; Rode 2011; Rouse 2007; Rozenberg 2012) as all expected outcomes were reported. One study was assessed as being at high risk of bias, because one of the outcomes was incompletely reported on (Facchinetti 2007) and in one study it was difficult to assess selective reporting based on a translation of the original report (Papiernik 1970). In all the other study reports, it was not possible to determine whether or not selection bias was present (Briery 2011; Elsheikhah 2010; Glover 2011; Moghtadaei 2008; Ndoni 2010; Rozenberg 2012; Saghafi 2011a; Senat 2012; Serra 2013; Sharami 2010).

## Other potential sources of bias

Twenty-one studies were assessed as being at low risk of bias for other potential sources of bias based on baseline characteristics being similar between groups and no other bias apparent (Borna 2008; Briery 2011; Caritis 2009; Combs 2010; Combs 2011; da Fonseca 2003; Facchinetti 2007; Fonseca 2007; Glover 2011; Hassan 2011; Hauth 1983; Johnson 1975; Lim 2011; Meis 2003; Norman 2009; O'Brien 2007; Papiernik 1970; Rai 2009; Rode 2011; Saghafi 2011a; Sharami 2010). In the remaining studies, it was not possible to determine whether or not other sources of bias were present (Aboulghar 2012; Akbari 2009; Cetingoz 2011; Combs 2011a; Elsheikhah 2010; Grobman 2012; Hartikainen 1980; Ibrahim 2010; Majhi 2009; Moghtadaei 2008; Ndoni 2010; Rouse 2007; Rozenberg 2012; Senat 2012; Serra 2013).

## Assessment of studies that included multiple pregnancies

We assessed whether studies that included multiple pregnancies accounted appropriately for non-independence of babies from the same pregnancy in the analysis. There were 14 studies that included a multiple pregnancy (Aboulghar 2012; Caritis 2009; Cetingoz 2011; Combs 2010; Combs 2011; Elsheikhah 2010; Fonseca 2007; Hartikainen 1980; Lim 2011; Norman 2009; Rode 2011; Rouse 2007; Senat 2012; Serra 2013) and in seven studies adjustment appears to have been made in the analysis (Caritis 2009; Combs 2010; Combs 2011; Fonseca 2007; Lim 2011; Norman 2009; Rode 2011). In the remaining seven studies (Aboulghar 2012; Cetingoz 2011; Elsheikhah 2010; Hartikainen 1980; Rouse 2007; Senat 2012; Serra 2013), it is not clear that any adjustment was made.

There were insufficient data presented in the trial reports to allow us to carry out necessary adjustment for cluster design effect ourselves and, although in several trials results had already been adjusted, we were not able to present these data in our data and analyses tables because they were not reported in a consistent way.

## Effects of interventions

Thirty-six randomised controlled trials (8523 women and 12,515 infants) in total were included in this review.

Data were only available in a suitable format from 30 randomised controlled trials involving a total of 7561 women and 10,114 infants. Data from these 30 trials contributed data that were included in meta-analyses. As the aetiology of preterm birth is multifactorial, results are presented according to the reason considered to be at risk for preterm birth (past history of spontaneous preterm birth (including preterm premature rupture of membranes), ultrasound identified short cervical length, multiple pregnancy, prior presentation with threatened preterm labour, and other reason for risk of preterm birth).

### Progesterone versus placebo/no treatment for women with a past history of spontaneous preterm birth

Eleven randomised controlled trials involving a total of 1899 women and infants were included in the meta-analysis.

#### Primary outcomes

For women administered progesterone during pregnancy, there was a statistically significant reduction in perinatal mortality overall (six studies; 1453 women; risk ratio (RR) 0.50, 95% confidence interval (CI) 0.33 to 0.75), [Analysis 1.1](#). For the primary outcome preterm birth less than 34 weeks' gestation, there was also a statistically significant difference between progesterone when compared with placebo (five studies; 602 women; average RR 0.31, 95% CI 0.14 to 0.69), [Analysis 1.2](#). Substantial heterogeneity was evident for [Analysis 1.2](#) (heterogeneity:  $\text{Tau}^2 = 0.45$ ,  $\text{Chi}^2 = 9.15$ ,  $\text{df} = 4$  ( $P = 0.06$ ),  $I^2 = 56\%$ ) and so a random-effects model was used. Major neurodevelopmental handicap in childhood was not reported.

#### Secondary infant outcomes

For women administered progesterone during pregnancy, when compared with placebo, the results showed:

- preterm birth less than 37 weeks' gestation (10 studies; 1750 women; average RR 0.55, 95% CI 0.42 to 0.74); considerable heterogeneity was identified, and a random-effects model was used (heterogeneity:  $\text{Tau}^2 = 0.11$ ;  $\text{Chi}^2 = 29.60$ ,  $\text{df} = 9$  ( $P = 0.0005$ );  $I^2 = 70\%$ ), [Analysis 1.3](#). This was also evident for the intramuscular subgroup (four studies; 652 women; average RR 0.62, 95% CI 0.52 to 0.75), [Analysis 1.3.1](#). However, for the oral subgroup, no statistically significant differences were observed, [Analysis 1.3.3](#). A funnel plot for this analysis ([Figure 3](#)), including the 10 studies was very asymmetrical. This suggests that there may be some important biases or small-study effects in the set of studies in this analysis and so these results should be viewed with caution.

**Figure 3. Funnel plot of comparison: 1 Progesterone versus placebo/no treatment: previous history spontaneous preterm birth, outcome: 1.3 Preterm birth less than 37 weeks.**

There was also a statistically significant reduction in the risk of:

- infant birthweight less than 2500 g (four studies; 692 infants; RR 0.58, 95% CI 0.42 to 0.79), [Analysis 1.9](#);
- use of assisted ventilation (three studies; 633 women; RR 0.40, 95% CI 0.18 to 0.90), [Analysis 1.11](#);
- necrotising enterocolitis (three studies; 1170 infants; RR 0.30, 95% CI 0.10 to 0.89), [Analysis 1.16](#);
- neonatal death (six studies; 1453 women; RR 0.45, 95% CI 0.27 to 0.76), [Analysis 1.20](#);
- admission to neonatal intensive care unit (three studies; 389 women; RR 0.24, 95% CI 0.14 to 0.40), [Analysis 1.33](#).

For infant outcomes Apgar score less than seven at five minutes [Analysis 1.32](#), respiratory distress syndrome [Analysis 1.10](#), intrauterine fetal death [Analysis 1.19](#), intraventricular haemorrhage (all grades) [Analysis 1.12](#), intraventricular haemorrhage (grade III or IV) [Analysis 1.13](#), periventricular leucomalacia [Analysis 1.14](#), retinopathy of prematurity [Analysis 1.15](#), neonatal sepsis [Analysis 1.17](#), patent ductus arteriosus [Analysis 1.18](#), intrauterine fetal death [Analysis 1.19](#), or neonatal length of hospital stay [Analysis 1.34](#), there were no statistically significant differences identified.

**Secondary maternal outcomes**

For women administered progesterone during pregnancy, when compared with placebo, there was a statistically significant increase in:

- pregnancy prolongation in weeks (one study; 148 women; mean difference (MD) 4.47, 95% CI 2.15 to 6.79), [Analysis 1.31](#).

There were no statistically significant differences for the outcomes threatened preterm labour [Analysis 1.4](#), spontaneous vaginal birth [Analysis 1.5](#), adverse drug reaction [Analysis 1.30](#), caesarean birth [Analysis 1.6](#), use of antenatal corticosteroids [Analysis 1.7](#), or the use of antenatal tocolysis [Analysis 1.8](#).

**Secondary childhood outcomes**

There were no statistically significant differences identified for the outcomes developmental delay [Analysis 1.21](#), intellectual impairment [Analysis 1.22](#), motor impairment [Analysis 1.23](#), visual impairment [Analysis 1.24](#), hearing impairment [Analysis 1.25](#), cerebral palsy [Analysis 1.26](#), learning difficulties [Analysis 1.27](#), height less than fifth centile [Analysis 1.28](#), weight less than the fifth centile [Analysis 1.29](#), infant weight at six, 12 and 24 months' follow-up [Analysis 1.34](#); [Analysis 1.35](#); [Analysis 1.36](#), infant length (cm) at six, 12 and 24 months' follow-up [Analysis 1.38](#); [Analysis 1.39](#);

[Analysis 1.40](#), and infant head circumference (cm) at six, 12 and 24 months' follow-up [Analysis 1.41](#); [Analysis 1.42](#); [Analysis 1.43](#).

### **Effect of route of administration, time of commencing therapy, and dose of progesterone**

We investigated statistical heterogeneity ( $I^2 > 30\%$ ) by performing subgroup analyses where possible for all outcomes and found no differential effect on the majority of outcomes examined when considering route of administration of progesterone (intramuscular versus vaginal versus oral). However, for respiratory distress syndrome, the subgroup analysis indicated a differential effect between the different routes of administration (test for subgroup differences:  $P = 0.001$ ,  $I^2 = 84.8\%$ , [Analysis 1.10](#)), although only one trial was included in each subgroup of intramuscular versus vaginal versus oral, [Analysis 1.10](#).

We performed subgroup analysis to investigate the differential effect of time of commencement of supplementation (prior to 20 weeks' gestation versus after 20 weeks' gestation) where outcome data allowed, and found no subgroup differences (test for subgroup differences:  $P = 0.28$ ,  $I^2 = 15.9\%$ , [Analysis 2.1](#)).

We also performed subgroup analysis by total weekly cumulative dose of progesterone (less than 500 mg versus greater than 500 mg) and found no differential effect for the majority of outcomes examined: [Analysis 3.1](#); [Analysis 3.2](#); [Analysis 3.3](#); [Analysis 3.4](#); [Analysis 3.5](#); [Analysis 3.6](#); [Analysis 3.7](#); [Analysis 3.9](#); [Analysis 3.10](#); [Analysis 3.11](#); [Analysis 3.12](#). However, for intraventricular haemorrhage (all grades), the subgroup analysis indicated a differential effect between the different doses of progesterone (test for subgroup differences:  $P = 0.04$ ,  $I^2 = 76.2\%$ , [Analysis 1.38](#)), although only one trial was included in each subgroup of intramuscular versus vaginal versus oral, [Analysis 1.10](#).

### **Progesterone versus placebo for women with a short cervix identified on ultrasound**

Four randomised controlled trials involving a total of 1556 women and infants were included in the meta-analysis.

#### **Primary outcomes**

For women administered progesterone during pregnancy, for the primary outcome perinatal death, there were no statistically significant differences identified when compared with placebo, [Analysis 4.1](#). Women administered progesterone were significantly less likely to have a preterm birth at less than 34 weeks' gestation (two studies; 438 women; RR 0.64, 95% CI 0.45 to 0.90), [Analysis 4.2](#). Major neurodevelopmental handicap in childhood was not reported.

#### **Secondary infant outcomes**

For women administered progesterone during pregnancy, for the outcome preterm birth at less than 37 weeks' gestation, there were no statistically significant differences identified when compared with placebo, [Analysis 4.12](#). However, women administered progesterone were significantly less likely to have a preterm birth at less than 28 weeks' gestation (two studies; 1115 women; RR 0.59, 95% CI 0.37 to 0.93), [Analysis 4.13](#).

For infant outcomes infant birthweight less than 2500 g [Analysis 4.14](#), respiratory distress syndrome [Analysis 4.15](#), Apgar score less than seven at five minutes [Analysis 4.16](#), need for

assisted ventilation [Analysis 4.17](#), intraventricular haemorrhage (all grades) [Analysis 4.18](#), intraventricular haemorrhage (grades III or IV) [Analysis 4.19](#), periventricular leucomalacia [Analysis 4.20](#), retinopathy of prematurity [Analysis 4.21](#), necrotising enterocolitis [Analysis 4.22](#), neonatal sepsis [Analysis 4.23](#), intrauterine fetal death [Analysis 4.24](#), neonatal death [Analysis 4.25](#) or admission to neonatal intensive care unit [Analysis 4.26](#), there were no statistically significant differences identified.

#### **Secondary maternal outcomes**

Women administered progesterone were significantly more likely to experience the adverse drug reaction urticaria (one study; 654 women; RR 5.03, 95% CI 1.11 to 22.78), [Analysis 4.7](#). For all other maternal outcomes, threatened preterm labour [Analysis 4.3](#), prelabour spontaneous rupture of membranes [Analysis 4.4](#), adverse drug reactions (any, injection site, nausea) [Analysis 4.5](#); [Analysis 4.6](#); [Analysis 4.8](#), pregnancy prolongation [Analysis 4.9](#), caesarean section [Analysis 4.10](#), or antenatal tocolysis [Analysis 4.11](#), there were no statistically significant differences identified.

#### **Secondary childhood outcomes**

None of the secondary childhood outcomes were reported.

### **Effect of route of administration, time of commencing therapy, and dose of progesterone**

We investigated statistical heterogeneity ( $I^2 > 30\%$ ) by performing subgroup analyses where possible for all outcomes and found no differential effect on the outcomes examined when considering route of administration of progesterone (intramuscular versus vaginal), [Analysis 4.20](#); [Analysis 4.21](#); [Analysis 4.23](#). It was not possible to assess the effect of gestational age at commencing therapy.

We also performed subgroup analysis by total weekly cumulative dose of progesterone (less than 500 mg versus greater than 500 mg) and found no differential effect for the two outcomes examined: [Analysis 5.1](#); [Analysis 5.2](#).

### **Progesterone versus placebo for women with a multiple pregnancy**

Ten randomised controlled trials involving a total of 3395 women and 6178 infants were included in the meta-analysis.

One trial ([Serra 2013](#)) consisted of three groups: progesterone 200 mg versus progesterone 400 mg versus placebo. This trial has been analysed as separate pair-wise comparisons, with separate analyses for progesterone 200 mg versus placebo ([Analysis 6.1](#); [Analysis 6.2](#); [Analysis 6.3](#); [Analysis 6.5](#); [Analysis 6.9](#); [Analysis 6.10](#); [Analysis 6.11](#); [Analysis 6.12](#); [Analysis 6.13](#); [Analysis 6.14](#); [Analysis 6.21](#); [Analysis 6.24](#); [Analysis 6.25](#); [Analysis 6.26](#)) and progesterone 400 mg versus placebo ([Analysis 6.27](#); [Analysis 6.28](#); [Analysis 6.29](#); [Analysis 6.30](#); [Analysis 6.31](#); [Analysis 6.32](#); [Analysis 6.33](#); [Analysis 6.34](#); [Analysis 6.35](#); [Analysis 6.36](#); [Analysis 6.37](#); [Analysis 6.38](#); [Analysis 6.39](#); [Analysis 6.40](#); [Analysis 6.41](#); [Analysis 6.42](#); ; [Analysis 7.1](#); [Analysis 7.2](#); [Analysis 7.3](#)).

#### **Primary outcomes**

For women administered progesterone during pregnancy, for the primary outcomes perinatal death [Analysis 6.1](#), [Analysis 6.27](#), and preterm birth less than 34 weeks' gestation [Analysis 6.2](#); [Analysis 6.28](#), there were no statistically significant differences identified

when compared with placebo. Major neurodevelopmental handicap in childhood was not reported.

### Secondary infant outcomes

For women administered progesterone during pregnancy, when compared with placebo, there were no statistically significant differences identified in the risk of birth before 37 weeks [Analysis 6.11](#); [Analysis 6.33](#) or 28 weeks [Analysis 6.12](#); [Analysis 6.34](#), infant birthweight less than 2500 g [Analysis 6.13](#); [Analysis 6.35](#), Apgar score less than seven at five minutes [Analysis 6.14](#); [Analysis 6.36](#), respiratory distress syndrome [Analysis 6.15](#), need for ventilation [Analysis 6.16](#); [Analysis 6.37](#), intraventricular haemorrhage [Analysis 6.17](#); [Analysis 6.18](#), periventricular leucomalacia [Analysis 6.19](#), retinopathy of prematurity [Analysis 6.20](#), chronic lung disease [Analysis 6.21](#), necrotising enterocolitis [Analysis 6.22](#), neonatal sepsis [Analysis 6.23](#), fetal death [Analysis 6.24](#); [Analysis 6.38](#), neonatal death [Analysis 6.25](#); [Analysis 6.39](#), or admission to neonatal intensive care unit (NICU) [Analysis 6.26](#); [Analysis 6.40](#). Due to extreme heterogeneity, we did not combine data from trials for the outcomes neonatal length of hospital stay or patent ductus arteriosus.

### Secondary maternal outcomes

For women administered progesterone during pregnancy, when compared with placebo, there were no statistically significant differences identified in any of the following maternal outcomes: prelabour spontaneous rupture of membranes [Analysis 6.3](#), adverse drug reaction [Analysis 6.4](#), caesarean section [Analysis 6.5](#), spontaneous birth [Analysis 6.6](#), assisted birth [Analysis 6.7](#), satisfaction with the therapy [Analysis 6.8](#), antenatal tocolysis [Analysis 6.9](#), or antenatal corticosteroids [Analysis 6.10](#).

### Secondary childhood outcomes

None of the secondary childhood outcomes were reported.

### Sensitivity analyses to account for multiple pregnancies

For multiple pregnancies we had planned to analyse neonatal data as 'clusters' to account for dependency between twins and triplets. We anticipated that the degree of dependence between twins would vary at the outcome level i.e. in the case of preterm birth the dependency (ICC) is likely to be high, whereas in some outcomes, such as perinatal death or morbidity, the ICC may be much lower. However, there were insufficient data presented in the trial reports to allow us to carry out necessary adjustment for cluster design effect ourselves and, although in several trials results had already been adjusted, we were not able to present these data in our data and analyses tables because they were not reported in a consistent way.

For the primary outcome perinatal death, we therefore carried out a sensitivity analysis assuming two extremes. In the first we assumed complete dependence between infants in multiple pregnancies, i.e. we assumed outcomes were the same for all infants within that pregnancy; in this case the effective sample size for twin pregnancies would be the total number of women rather than infants, and for infant outcomes all event rates and sample sizes were therefore divided by two. In the second sensitivity analyses we assumed very limited dependence (1%) and in this case event rates and sample sizes were divided by 1.01. Results from sensitivity analyses were very similar to those from the unadjusted analyses although the effect estimates changed slightly

due to rounding up of event rates and sample sizes, and the 95% CIs were generally slightly wider. Adjusted analyses showed that for women administered progesterone during pregnancy, for the primary outcome perinatal death, there were no statistically significant differences identified when compared with placebo. (Data not shown, available from the authors on request).

### Effect of route of administration, time of commencing therapy, and dose of progesterone

We investigated statistical heterogeneity ( $I^2 > 30\%$ ) by performing subgroup analyses and found no differential effect on the majority of outcomes examined when considering route of administration of progesterone (intramuscular versus vaginal). However, for spontaneous birth, infant birthweight less than 2500 g and admission to NICU, the subgroup analyses indicated a differential effect between the different routes of administration (test for subgroup differences:  $P = 0.0008$ ,  $I^2 = 91.1\%$ , [Analysis 6.6](#);  $P = 0.02$ ,  $I^2 = 80.8\%$  [Analysis 6.13](#);  $P = 0.009$ ,  $I^2 = 85.5\%$ , [Analysis 6.26](#)) although it must be noted that in [Analysis 6.6](#); [Analysis 6.26](#), some of the subgroups contained only one trial.

We performed subgroup analysis to investigate the differential effect of time of commencement of supplementation (prior to 20 weeks' gestation versus after 20 weeks' gestation) where outcome data allowed, and found no subgroup differences for the outcomes examined, [Analysis 7.1](#); [Analysis 7.2](#); [Analysis 7.3](#).

We also performed subgroup analysis by total weekly cumulative dose of progesterone (less than 500 per week mg versus greater than 500 mg per week) and found no differential effect for the majority of outcomes examined, [Analysis 8.1](#); [Analysis 8.2](#); [Analysis 8.3](#); [Analysis 8.4](#); [Analysis 8.5](#); [Analysis 8.6](#); [Analysis 8.7](#). However, for infant birthweight less than 2500 g and admission to NICU, the subgroup analyses indicated a differential effect between the cumulative doses of progesterone (test for subgroup difference:  $P = 0.02$ ,  $I^2 = 80.8\%$ , [Analysis 8.5](#);  $P = 0.009$ ,  $I^2 = 85.5\%$ , [Analysis 8.8](#)).

### Progesterone versus placebo/no treatment for women following presentation with threatened preterm labour

Five randomised controlled trials involving a total of 384 women and infants were included in the meta-analysis.

### Primary outcomes

For women administered progesterone during pregnancy, for the primary outcomes perinatal death [Analysis 9.1](#), and preterm birth less than 34 weeks' gestation [Analysis 9.2](#), there were no statistically significant differences identified when compared with placebo. Major neurodevelopmental handicap in childhood was not reported.

### Secondary infant outcomes

For women administered progesterone during pregnancy, when compared with placebo, there was a statistically significant reduction in the risk of:

- infant birthweight less than 2500 g (one study; 70 infants; RR 0.52, 95% CI 0.28 to 0.98), [Analysis 9.11](#).

There were no statistically significant differences for any of the other outcomes analysed: preterm birth less than 37 weeks' gestation [Analysis 9.10](#), respiratory distress syndrome [Analysis](#)

9.12, intraventricular haemorrhage grade III or IV [Analysis 9.13](#), periventricular leucomalacia [Analysis 9.14](#), needed for mechanical ventilation [Analysis 9.15](#), necrotising enterocolitis [Analysis 9.16](#), neonatal sepsis [Analysis 9.17](#), fetal death [Analysis 9.18](#), neonatal death [Analysis 9.19](#), or neonatal length of hospital stay [Analysis 9.20](#).

### Secondary maternal outcomes

For women administered progesterone during pregnancy, when compared with placebo, there were no statistically significant differences for any of the outcomes analysed: pregnancy prolongation [Analysis 9.3](#); [Analysis 9.4](#); [Analysis 9.5](#); [Analysis 9.6](#), spontaneous vaginal birth [Analysis 9.7](#), caesarean section [Analysis 9.8](#), or use of tocolysis [Analysis 9.9](#).

### Secondary childhood outcomes

There were no secondary childhood outcomes reported.

### Effect of route of administration, time of commencing therapy, and dose of progesterone

We investigated statistical heterogeneity ( $I^2 > 30\%$ ) by performing subgroup analyses where possible for all outcomes and found no differential effect on some of the outcomes examined when considering route of administration of progesterone (intramuscular versus vaginal), [Analysis 9.2](#); [Analysis 9.9](#); [Analysis 9.12](#); [Analysis 9.17](#); [Analysis 9.19](#). However, for pregnancy prolongation and preterm birth less than 37 weeks' gestation, the subgroup analyses indicated a differential effect between the different routes of administration (test for subgroup differences:  $P = 0.001$ ,  $I^2 = 90.5\%$ , [Analysis 9.3](#);  $P = 0.04$ ,  $I^2 = 75.6\%$ , [Analysis 9.10](#)), although it must be noted that in both analyses the subgroups contained only one trial.

It was not possible to assess the effect of gestational age at commencing therapy.

We also performed subgroup analysis by total weekly cumulative dose of progesterone (less than 500 mg versus greater than 500 mg) and found no differential effect for three outcomes examined: [Analysis 10.3](#); [Analysis 10.4](#); [Analysis 10.5](#). However, for the two outcomes, pregnancy prolongation and preterm birth less than 37 weeks' gestation, the subgroup analyses indicated a differential effect between the different drug doses (test for subgroup differences:  $P = 0.001$ ,  $I^2 = 90.5\%$ , [Analysis 10.1](#);  $P = 0.04$ ,  $I^2 = 75.6\%$ , [Analysis 10.2](#)).

### Progesterone versus placebo for women with 'other' risk factors for preterm birth

Three randomised controlled trials involving a total of 482 women and infants were included in the meta-analysis. Data from a fourth study ([Moghtadaei 2008](#)), could not be included in the meta-analysis because the number of women randomised to each group was not reported in the brief abstract report of the study.

### Primary outcomes

For women administered progesterone during pregnancy, for the primary outcomes perinatal death [Analysis 11.1](#) and preterm birth less than 34 weeks' gestation [Analysis 11.2](#), there were no statistically significant differences identified when compared with placebo. The outcome major neurodevelopmental handicap in childhood were not reported.

### Secondary infant outcomes

For women administered progesterone during pregnancy, when compared with placebo, there was a statistically significant reduction in the risk of:

- infant birthweight less than 2500 g (three studies; 482 infants; RR 0.48, 95% CI 0.25 to 0.91) [Analysis 11.4](#).

In addition, for women administered progesterone who were considered to be at risk of preterm birth for 'other' reasons, when compared with placebo, there were no statistically significant differences for the outcomes preterm birth less than 37 weeks' gestation [Analysis 11.3](#)., perinatal death [Analysis 11.1](#), intrauterine fetal death [Analysis 11.5](#) or neonatal death [Analysis 11.6](#).

### Secondary childhood outcomes

There were no secondary childhood outcomes reported.

### Effect of route of administration, time of commencing therapy, and dose of progesterone

We investigated statistical heterogeneity ( $I^2 > 30\%$ ) by performing subgroup analysis for perinatal death [Analysis 12.1](#), preterm birth less than 37 weeks [Analysis 12.2](#), and infant birthweight less than 2500 g, [Analysis 12.3](#), and no differential effect was observed related for gestational age at commencing therapy, (test for subgroup differences:  $P = 0.10$ ,  $I^2 = 63.9\%$ , [Analysis 12.2](#);  $P = 0.19$ ,  $I^2 = 42.2\%$ , [Analysis 12.3](#)).

## DISCUSSION

The randomised trials identified assessed the use of progesterone in women considered to be at increased risk of preterm birth by virtue of history of spontaneous preterm birth, ultrasonographic evaluation of cervical length, presentation in threatened preterm labour, multiple pregnancy, or other reasons (including 'high preterm risk score' and active military duty).

### Summary of main results

#### Progesterone for women with a past history of spontaneous preterm birth

For women with a past history of spontaneous preterm birth, there was a statistically significant reduction in the risk of the primary outcomes, perinatal death and in the risk of preterm birth less than 34 weeks' gestation. The reduction in risk of perinatal death is confined to the subgroup of women receiving intramuscular progesterone. There was significant heterogeneity identified for the outcomes preterm birth before 34 and 37 weeks' gestation, with evidence of funnel plot asymmetry, raising questions about potential bias and therefore caution in interpretation. For the secondary infant and maternal outcomes, the use of progesterone was associated with a reduction in the risk of infant birthweight less than 2500 g, use of assisted ventilation, necrotising enterocolitis, neonatal death, admission to neonatal intensive care unit, preterm birth less than 37 weeks' gestation and a significant increase in prolongation in pregnancy prolongation. There were no significant differences identified for other secondary infant and maternal health outcomes with the use of progesterone. Information related to childhood health and well being is limited, with only two trials reporting two-year follow-up results to date ([Northen 2007](#); [O'Brien 2007](#)), in which there were no documented differences in growth or

developmental outcomes between those infants exposed in utero to progesterone and those to placebo. There was no differential effect on outcomes in terms of time of commencing therapy and dose of progesterone from the available evidence.

Further information is required about the optimal route of administration of progesterone, with the largest study to date using vaginal progesterone gel suggesting no benefit in this group of women (O'Brien 2007).

#### **Progesterone for women with a short cervix identified on ultrasound**

In the trials to date assessing the role of progesterone in women with a short cervix identified on ultrasound (Fonseca 2007; Grobman 2012; Hassan 2011; Rozenberg 2012), there were no statistically significant differences identified for the primary outcome perinatal death. Women administered progesterone were significantly less likely to have preterm birth less than 34 weeks' gestation. For the secondary infant outcomes, the use of progesterone was associated with a reduction in risk of preterm birth at less than 28 weeks' gestation. There was also a significant increase in the risk urticaria in women receiving progesterone. Further information is required about the risk of other infant health outcomes, and maternal health outcomes in this group of women. Reporting of childhood outcomes is lacking, with no trials reporting this information to date. The relative efficacy of progesterone compared with cerclage for women with a short cervix remains uncertain, as does the use of progesterone as an adjunct therapy following cerclage placement (Conde-Agudelo 2013).

#### **Progesterone for women with a multiple pregnancy**

The role of progesterone in women with a multiple pregnancy is less clear, with no identified differences in the primary outcomes perinatal death, and preterm birth less than 34 weeks' gestation. There were also no differences identified for the other secondary infant and maternal health outcomes. Information relating to long-term childhood health outcomes is unavailable to date. There are several ongoing randomised trials assessing the role of intramuscular (Nassar 2007) and vaginal (Wood 2007) progesterone in women with a multiple pregnancy which will contribute information about the role of progesterone in this group of women.

For multiple pregnancies, we had planned to analyse neonatal data as 'clusters' to account for dependency between twins and triplets. We anticipated that the degree of dependence between twins would vary at the outcome level i.e. in the case of preterm birth the dependency (ICC) is likely to be high, whereas in some outcomes such as perinatal death or morbidity, the ICC may be much lower. However, there were insufficient data presented in the trial reports to allow us to carry out necessary adjustment for cluster design effect ourselves and, although in several trials results had already been adjusted, we were not able to present these data in our data and analyses tables because they were not reported in a consistent way. In future updates, we will contact trial authors for additional information to allow us to carry out necessary adjustments in the analysis of the neonatal data.

#### **Progesterone for women following presentation with threatened preterm labour**

The role of progesterone for women following presentation with threatened preterm labour remains uncertain. The identified

randomised trials indicate a reduction in only the risk of infant birthweight less than 2500 g. However, the outcomes have been reported in only five small trials (332 women), with only four contributing data to meta-analysis (211 women) and are underpowered to detect differences in both maternal and infant health outcomes. There is an ongoing randomised trial assessing the role of vaginal progesterone in women presenting with symptoms or signs of threatened preterm labour which will contribute information about the role of progesterone in this group of women (Martinez 2007).

#### **Progesterone versus placebo for women with 'other' risk factors for preterm birth**

The role of progesterone in women considered to be at risk of preterm birth for 'other reasons' is uncertain, with the three randomised trials that contributed data to the meta-analysis to date indicating no benefit in terms of perinatal death or preterm birth less than 37 weeks' gestation. However, the combined sample size of these trials is significantly underpowered to detect all but large differences in these outcomes.

There is evidence that progesterone for women with a history of previous preterm birth is associated with a reduction in preterm birth before 34 and 37 weeks gestation. As indicated earlier, there was considerable heterogeneity identified, in addition to evidence of funnel plot asymmetry, raising concern about potential bias. The observed reduction in perinatal mortality appears confined to the use of intramuscular progesterone.

However, information relating to longer-term infant and childhood outcomes is currently insufficient, with only two randomised trials reporting to date. Ongoing follow-up of children exposed to progesterone in utero remains a priority. Maternal outcomes following antenatal progesterone therapy were poorly reported in the available literature, including treatment side-effects, preferences of mode of administration and satisfaction of care. Further information is required on these important issues (Greene 2003; Iams 2003). In addition, there remains uncertainty as to the optimal dose of progesterone to be administered, the optimal route of administration, and the optimal gestational age at which to commence therapy. The American College of Obstetricians and Gynecologists have issued a committee opinion relating to the use of progesterone for the prevention of preterm birth, indicating the need for further information about the optimal mode of administration (ACOG 2003), including studies directly comparing the relative efficacy of vaginal and intramuscular preparations.

#### **Overall completeness and applicability of evidence**

The majority of studies to date have reported short-term maternal and infant outcomes, with only two studies reporting longer-term childhood outcomes (Northen 2007; O'Brien 2007).

As outlined above, there are a number of ongoing studies which will contribute to the evidence relating to the use of progesterone for women considered at risk of preterm birth. The trials by Crowther (Crowther 2007), Norman (Norman 2012), and Perlitz (Perlitz 2007) will contribute data from women with a prior preterm birth; van Os (van Os 2011) will contribute data from women with a short cervix identified by ultrasound; Nassar (Nassar 2007), and Wood (Wood 2007) will contribute data from women with a multiple pregnancy; and Martinez (Martinez 2007) will contribute data from women who present with symptoms or signs of threatened preterm labour.

## Quality of the evidence

Overall, the trials included in this review were considered to be of good to fair quality. Of the 36 included trials, adequate randomisation methods were described in 23 (Borna 2008; Briery 2011; Caritis 2009; Cetingoz 2011; Combs 2010; Combs 2011; Combs 2011a; da Fonseca 2003; Facchinetti 2007; Glover 2011; Grobman 2012; Hassan 2011; Lim 2011; Majhi 2009; Meis 2003; Norman 2009; O'Brien 2007; Rai 2009; Rode 2011; Rouse 2007; Rozenberg 2012; Senat 2012; Serra 2013), allocation concealment was assessed to be at low risk of bias in 23 (Aboulghar 2012; Briery 2011; Caritis 2009; Cetingoz 2011; Combs 2010; Combs 2011; Combs 2011a; da Fonseca 2003; Fonseca 2007; Glover 2011; Grobman 2012; Hassan 2011; Johnson 1975; Lim 2011; Majhi 2009; Meis 2003; Norman 2009; O'Brien 2007; Rai 2009; Rode 2011; Rouse 2007; Senat 2012; Serra 2013), and blinding was achieved with the use of a placebo agent in 25 (Aboulghar 2012; Briery 2011; Caritis 2009; Cetingoz 2011; Combs 2010; Combs 2011; Combs 2011a; da Fonseca 2003; Fonseca 2007; Glover 2011; Grobman 2012; Hartikainen 1980; Hassan 2011; Hauth 1983; Johnson 1975; Lim 2011; Meis 2003; Norman 2009; O'Brien 2007; Papiernik 1970; Rai 2009; Rode 2011; Rouse 2007; Serra 2013; Sharami 2010). Twenty-one of the 36 included studies were assessed as being at low risk of bias for other potential sources of bias (Borna 2008; Briery 2011; Caritis 2009; Combs 2010; Combs 2011; da Fonseca 2003; Facchinetti 2007; Fonseca 2007; Glover 2011; Hassan 2011; Hauth 1983; Johnson 1975; Lim 2011; Meis 2003; Norman 2009; O'Brien 2007; Papiernik 1970; Rai 2009; Rode 2011; Saghafi 2011a; Sharami 2010).

We assessed whether studies that included multiple pregnancies accounted appropriately for non-independence of babies from the same pregnancy in the analysis. There were 14 studies that included a multiple pregnancy (Aboulghar 2012; Caritis 2009; Cetingoz 2011; Combs 2010; Combs 2011; Elsheikhah 2010; Fonseca 2007; Hartikainen 1980; Lim 2011; Norman 2009; Rode 2011; Rouse 2007; Senat 2012; Serra 2013) and in seven studies adjustment appears to have been made in the analysis (Caritis 2009; Combs 2010; Combs 2011; Fonseca 2007; Lim 2011; Norman 2009; Rode 2011). In the remaining seven studies (Aboulghar 2012; Cetingoz 2011; Elsheikhah 2010; Hartikainen 1980; Rouse 2007; Senat 2012; Serra 2013), it is not clear that any adjustment was made. There was not enough information in the trial reports for us to carry out the necessary adjustments ourselves in the analysis of neonatal outcomes. This information will be sought for future updates.

## Potential biases in the review process

The possibility of introducing bias was present at every stage of the reviewing process. We attempted to minimise bias in a number of ways: two review authors assessed eligibility for inclusion, carried out data extraction and assessed risk of bias. Each worked independently. Nevertheless, the process of assessing risk of bias is not an exact science and includes many personal judgements.

## Agreements and disagreements with other studies or reviews

Despite the differences in methodology and included studies, our findings of a reduction in preterm birth before 34 weeks' and 28 weeks' gestation for women with a short cervix identified on ultrasound examination, and a reduction in infant respiratory distress syndrome are consistent with those reported in an individual patient data meta-analysis by Romero and colleagues

(Romero 2012). Similarly, the findings of a proposed individual patient data meta-analysis for women with a multiple pregnancy are awaited to evaluate if there are specific subgroups of women with a multiple pregnancy who may receive benefit from progesterone therapy (Schuit 2012).

## AUTHORS' CONCLUSIONS

### Implications for practice

#### Summary of the available information

#### Progesterone for women with a past history of spontaneous preterm birth

The use of progesterone in this group of women is associated with a reduction in the risk of perinatal death, preterm birth before 34 weeks' and 37 weeks' gestation, infant birthweight less than 2500 g, use of assisted ventilation, necrotising enterocolitis, neonatal death, admission to neonatal intensive care unit, and prolongation of pregnancy. There is limited information about longer-term childhood health. In addition, further information is required as to the optimal route of administration of progesterone, the optimal dose to be administered, and the best time to commence therapy.

#### Progesterone for women with a short cervix identified on ultrasound

The use of progesterone in this group of women is associated with a reduction in the risk of preterm birth less than 34 and 28 weeks' gestation, and a significant increase in the risk urticaria in women receiving progesterone. Further information is required about other maternal, infant and childhood health outcomes. Of particular note, there are no comparative data reported on longer-term childhood health from trials conducted to date. In addition, further information is required as to the optimal route of administration of progesterone, the optimal dose to be administered, and the best time to commence therapy.

#### Progesterone for women with a multiple pregnancy

The use of progesterone in this group of women is not associated with any statistically significant differences in perinatal death, preterm birth and other maternal, infant, and childhood health outcomes.

#### Progesterone for women following presentation with threatened preterm labour

The use of progesterone in this group of women was associated with a statistically significant reduction in the risk of infant birthweight less than 2500 g. However, for all other outcomes, the role of progesterone for women presenting following symptoms or signs of threatened preterm labour is uncertain.

#### Progesterone for women with 'other' risk factors for preterm birth

The use of progesterone in this group of women was associated with a statistically significant reduction in the risk of infant birthweight less than 2500 g. However, for all other outcomes, the role of progesterone in women considered to be at risk of preterm birth for 'other reasons' is uncertain.

## Implications for research

Further well-designed randomised controlled trials are required to assess the optimal timing, mode of administration and dose of administration of progesterone when given to women considered to be at increased risk of early birth, by virtue of previous history of spontaneous preterm birth, short cervix identified by transvaginal ultrasound, following arrest of symptoms or signs of threatened preterm labour, or on the basis of 'other' risk factors. Assessment of longer-term infant and childhood outcomes remains a priority.

There are several randomised trials that are currently addressing the use of progesterone for preterm birth which will contribute data in the future - see [Characteristics of ongoing studies](#) for details.

## ACKNOWLEDGEMENTS

We thank Lynn Hampson for searching the trials register.

We would like to thank Gabriella Behzadi for the translation of the paper by [Akbari 2009](#) et al.

We would like to thank Therese Dowswell, Research Associate in the Cochrane Pregnancy and Childbirth Group, for her support and advice with the update in 2013.

As part of the pre-publication editorial process, this review has been commented on by six peers (an editor and five referees who are external to the editorial team), a member of the Pregnancy and Childbirth Group's international panel of consumers and the Group's Statistical Adviser.

The National Institute for Health Research (NIHR) is the largest single funder of the Cochrane Pregnancy and Childbirth Group. The views and opinions expressed therein are those of the authors and do not necessarily reflect those of the NIHR, NHS or the Department of Health.

## CHARACTERISTICS OF STUDIES

### Characteristics of included studies [ordered by study ID]

#### Aboulghar 2012

Methods	Single-centre prospective placebo-controlled randomised clinical trial. IVF Center, Cairo, Egypt.
Participants	313 women at high risk of preterm birth with pregnancies conceived by IVF or ICSI. Inclusion criteria: Healthy pregnant women who conceived after IVF/ICSI between 18-24 weeks of gestation, with a first pregnancy, singleton or dichorionic twins, normal uterine and cervical anatomy, and normal fetal anatomy.

**Aboulghar 2012** (Continued)

Exclusion criteria: Previous pregnancy, serious fetal anomalies for which termination may be considered such as major heart anomaly or major CNS anomaly.

All women received progesterone injections as luteal phase support which they continued if pregnant until the day of the first ultrasound

Interventions	Vaginal progesterone 200 mg twice daily from randomisation until delivery or 37 weeks' gestation. Total number randomised: n = 161 women (161 analysed, 210 babies).  Placebo vaginal suppositories from randomisation until 37 weeks' gestation. Total number randomised: n = 152 women (145 women analysed, 187 babies).	
Outcomes	Primary outcomes were: preterm birth of singleton and twin pregnancies before 37 completed weeks and before 34 completed weeks.  Secondary outcomes: neonatal morbidity and mortality (live-born children who died < 28 days after delivery) and take-home baby rate (live-birth rate per patient). Birthweight > 2500 g; 1500-2500 g; < 1500 g; NICU admissions.	
Notes		
<b>Risk of bias</b>		
<b>Bias</b>	<b>Authors' judgement</b>	<b>Support for judgement</b>
Random sequence generation (selection bias)	Unclear risk	States, "Dark, sealed envelopes containing the intervention taken from a table of numbers" – not clear how the table of number generated – does not state "random number table".
Allocation concealment (selection bias)	Low risk	Refers to "dark, sealed, sequentially numbered envelopes" and the envelopes were picked by a nurse not involved in the study. The envelopes had been created by a third party not involved in the allocation process.
Incomplete outcome data (attrition bias) All outcomes	Low risk	Study flow diagram clearly displays participant flow in the study.  410 women recruited, 313 randomised; none lost to follow-up in progesterone group and 6 lost to follow-up in placebo group and 1 excluded because of termination of pregnancy after diagnosis of trisomy 21.  States "Intention-to-treat principle was followed during data analysis."
Selective reporting (reporting bias)	Low risk	All expected outcome results reported.
Other bias	Unclear risk	None apparent, although baseline characteristics table not presented.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	States "single blinding" and that "the patient was informed about the allocated arm" so presumably the clinician/personnel were blinded.
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Not clear, but probably low risk. Placebo-controlled trial.

**Akbari 2009**

Methods	Randomised.  Single centre, Lorestan.
Participants	150 women randomised: 75 to each group.  Inclusion criteria: 1. Single child pregnancy with the exact age of conception based on LMP was determined and was verified by sonogram before reaching 20 weeks. If the LMP was not available the exact age of pregnancy was based on 2 sonograms that were verified on at least 2 separate weeks; 2. Women with a history of 1 or 2 previous early childbirths before reaching 37 weeks of pregnancy or women with a history of prophylactic cervical cerclage or uterine anomalies (unicornuate uterus, bicornuate uterus, septate uterus, arcuate uterus, uterus didelphys); and 3. Older than 18 years, younger than 35 years.  Exclusion criteria: 1. Rupture of membranes PROM; 2. Large known fetal anomalies; 3 Cervix dilatation larger than 4 cm; 4. Contraindications for tocolysis including fetal distress, chorioamnionitis, pre-eclampsia, and haemodynamic instability; 5. Allergies to progesterone (dizziness, mygan, visual disturbances, depression, and increased blood sugar during previous consumption of this drug were considered allergic reactions to the hormone.); 6. Not following up with patients; 7. Multiple pregnancies; 8.The existence of an illness in the mother that necessitated medication, such as high blood pressure, cancer, tension, thromboembolic disease, Kennedy's disease, illnesses that are treated for asthma with oral beta-adrenergic; 9. Age younger than 18 or older than 35; 10. Existence of IUGR fetuses; 11. Unwaranted vaginal bleeding.
Interventions	Experimental intervention: 100 mg of prophylactic vaginal progesterone daily between 24 <sup>th</sup> and 34 <sup>th</sup> week of gestation - Cyclogest.  Control/Comparison intervention: the other group received no treatment and were monitored.
Outcomes	Mean gestational age at time of delivery.  Preterm delivery before 37 <sup>th</sup> week gestation.  Preterm delivery before 34 <sup>th</sup> week gestation.  Respiratory distress syndrome.  Low birthweight.  Birthweight.  Need for oxygen.  Infant Apgar score.  Need for mechanical ventilator.  Hospitalisation in NICU.
Notes	
<b>Risk of bias</b>	
<b>Bias</b>	<b>Authors' judgement</b> <b>Support for judgement</b>
Random sequence generation (selection bias)	Unclear risk    Not clear "150 women that had passed the entrance criterion to the study were divided randomly into two groups of 75."
Allocation concealment (selection bias)	Unclear risk    Not reported.

**Akbari 2009** (Continued)

Incomplete outcome data (attrition bias) All outcomes	Unclear risk	3 individuals from the control group and 4 from the group receiving progesterone were excluded from the study – reasons for exclusion not clear – but in table of results – 6 people appear to be missing from denominator for the progesterone group (report 69) and not 4 as described?  Results presented for 69 women in progesterone group and 72 in control.
Selective reporting (reporting bias)	Low risk	All expected outcomes appear to have been reported.
Other bias	Unclear risk	Unclear.
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Not reported.
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not reported.

**Borna 2008**

Methods	Method of randomisation: random number table. Allocation concealment: unclear. Blinded outcome assessment: no. Completeness of follow-up: outcome data available for 70 women.
Participants	70 women presenting between 24 and 34 weeks' gestation with symptoms and signs of threatened preterm labour, where acute symptoms were arrested following use of tocolytic medication.
Interventions	Daily intravaginal pessary (400 mg) versus no treatment.
Outcomes	Interval from randomisation to birth.
Notes	Trial conducted in Tehran, Iran.

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Random number table.
Allocation concealment (selection bias)	Unclear risk	Unclear.
Incomplete outcome data (attrition bias) All outcomes	Low risk	Complete data available.
Selective reporting (reporting bias)	Low risk	All prespecified outcomes reported in the abstract appear to have been reported upon (latency period until delivery; respiratory distress syndrome; low birthweight; birthweight; recurrent preterm birth; admission to intensive care unit; neonatal sepsis).

**Borna 2008** (Continued)

Other bias	Low risk	Baseline characteristics were similar (see table 1, page 61).
Blinding of participants and personnel (performance bias) All outcomes	High risk	No blinding of care givers and women.
Blinding of outcome assessment (detection bias) All outcomes	High risk	No blinding of outcome assessment.

**Briery 2011**

Methods	Placebo-controlled double-blind randomised clinical trial.  Single site, USA.	
Participants	69 women randomised: 33 to 17-OH group and 36 to placebo.  Inclusion criteria: women who presented with singleton, vertex gestations to university's obstetric emergency area with a diagnosis of PPRM at 20-30 weeks' gestation, typically dated by ultrasound, were eligible.  Exclusion criteria: severe fetal or placental disease that might bias neonatal outcomes such as intrauterine growth restriction (< 5th percentile), suspected placental abruption, and confirmed placenta previa. Also excluded were patients already taking 17P, and some with signs and symptoms of chorioamnionitis, non-reassuring fetal assessments or severe medical/obstetric diseases such as sickle cell disease with the crisis, insulin-dependent diabetes, and severe pre-eclampsia.	
Interventions	Experimental intervention: weekly injections of 17P (250 mg) until 34 weeks or delivery, whichever came first.  Control/Comparison intervention: weekly injections of placebo until 34 weeks or delivery, whichever came first.	
Outcomes	Gestational age at birth; route of delivery; indications for delivery; birthweight; 5-minute Apgar score; total NICU days; significant neonatal morbidity (sepsis, seizures); respiratory distress syndrome; patent ductus arteriosus; intraventricular haemorrhage; necrotising enterocolitis; bronchopulmonary dysplasia; death during neonatal period.	
Notes		

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Random number table.
Allocation concealment (selection bias)	Low risk	Central allocation – pharmacy-controlled.
Incomplete outcome data (attrition bias) All outcomes	Low risk	2 patients lost – 1 person from 17P group who was previously enrolled in another study and 1 in placebo group refused the injection.

**Briery 2011** (Continued)

“All 69 were analyzed (intention to treat).”

Selective reporting (reporting bias)	Unclear risk	All expected outcomes, apart from intraventricular haemorrhage, are reported in tables – although number of seizures were recorded.
Other bias	Low risk	No significant differences in demographic statistics between groups.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	“Patients, their families, research personnel, and physicians/nurses were not aware of the study group assignment”. Also described as “double-blind”.
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not reported.

**Caritis 2009**

Methods	Randomised, double-blinded, placebo-controlled trial. 14 centres, USA.
Participants	134 women randomised: 71 to 17 alpha-hydroxyprogesterone caproate; 63 to placebo  Inclusion criteria: pregnant women with triplets were eligible if their gestational age was at least 16 weeks and no more than 20 weeks.  Exclusion criteria: serious fetal anomalies, 2 or more fetuses in 1 amniotic sac, suspected twin-to-twin transfusion syndrome, marked ultrasonographic growth discordance, planned non study progesterone therapy after 16 weeks, in-place or planned cerclage, major uterine anomaly, unfractionated heparin therapy at any dose, and major chronic medical diseases.
Interventions	Experimental intervention: weekly injections of 17-OHPC* (250 mg in 1 mL castor oil) starting at 16-20 weeks and ending at delivery or 35 weeks' gestation.  *17 Alpha-Hydroxyprogesterone Caproate  Control/Comparison intervention: weekly injections of placebo (1mL castor oil) starting at 16-20 weeks and ending at delivery or 35 weeks' gestation.
Outcomes	Primary outcomes: composite of delivery or fetal loss before 35 completed weeks of gestation (245 days) – fetal loss included: miscarriage, termination, or stillbirth occurring any time after randomisation.  Secondary outcomes: selected individual maternal and neonatal outcomes and a composite of serious neonatal outcomes.  Composite serious adverse neonatal outcomes included: neonatal death, respiratory distress syndrome, culture-proven sepsis, necrotising enterocolitis stage II or III, bronchopulmonary dysplasia, intraventricular haemorrhage grade III or IV, or periventricular leucomalacia or severe retinopathy of prematurity stage III or higher.
Notes	

**Caritis 2009** (Continued)

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"The simple urn method of randomization with stratification according to clinical center, was used to create a randomization sequence for each center."
Allocation concealment (selection bias)	Low risk	The injections were prepared by a research pharmacy and boxes of 17-OHPC and placebo were packaged for each centre according to randomisation sequences – so appears to be central allocation – pharmacy-controlled.
Incomplete outcome data (attrition bias) All outcomes	Low risk	<p>"Outcome data were available for 100% of the assigned women, and for all of the 402 fetuses."</p> <p>No exclusions apparent.</p> <p>ITT stated in statistical methods.</p>
Selective reporting (reporting bias)	Low risk	All expected outcomes appear to have been reported.
Other bias	Low risk	<p>The baseline characteristics of the 2 study groups were similar (Table 1).</p> <p>This study included women with multiple pregnancies (triplet) and there appears to be adjustment for neonatal binary outcomes - used log binomial regression to calculate relative risk.</p>
Blinding of participants and personnel (performance bias) All outcomes	Low risk	"The participating women, their caregivers, and the research personnel were not aware of the study group assignment". Also described as "double-blinded".
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not reported.

**Cetingoz 2011**

Methods	<p>Randomised placebo-controlled double-blind study.</p> <p>Department of Obstetrics and Gynecology, Istanbul.</p>
Participants	<p>160 women randomised: 84 allocated to intervention and 76 allocated to placebo.</p> <p>Inclusion criteria: high-risk pregnant women: twin pregnancies; pregnancies with at least 1 spontaneous preterm birth; uterine malformation.</p> <p>Exclusion criteria: not stated.</p>
Interventions	Experimental intervention: micronized progesterone (100 mg) administered daily by vaginal suppository between 24 and 34 weeks of gestation.

**Cetingoz 2011** (Continued)

Control/Comparison intervention: placebo (100 mg) administered daily by vaginal suppository between 24 and 34 weeks of gestation.

Outcomes

Delivery < 37 weeks.

Delivery < 34 weeks.

Preterm labour admission.

NICU admission.

Neonatal death.

Notes

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer-generated random-number list - "Patients were allocated according to randomised number table".
Allocation concealment (selection bias)	Low risk	Random-number list generated centrally by research hospital pharmacy.
Incomplete outcome data (attrition bias) All outcomes	Low risk	<p>170 high-risk women were eligible – 10 women were excluded before randomisation due to abortion (n = 2), delivery between 20 and 24 weeks (n = 7) and application of cervical cerclage (n = 1).</p> <p>160 women were randomised – 10 lost during follow-up, 6 from the placebo group and 4 from intervention group.</p> <p>150 women analysed (intervention group - n = 80 - prior preterm birth = 37; uterine malformation = 4; twin gestation = 39) and (placebo group - n = 70 - prior preterm birth = 34; uterine malformation = 8; twin gestation = 28).</p> <p>Analysis was performed according to ITT principle.</p>
Selective reporting (reporting bias)	Low risk	Yes – all expected outcomes reported
Other bias	Unclear risk	<p>Groups were similar in regard to age, pregravid BMI, parity, abortion, and ratio of high-risk groups according to baseline characteristics table. There were no statistically significant differences in demographics.</p> <p>This study included singleton and twin pregnancies - Odd ratio presented, but does not state whether any adjustments made in the analysis.</p>
Blinding of participants and personnel (performance bias) All outcomes	Low risk	"The participating women, their care-givers, and the research personnel were unaware of the woman's study-group assignments."
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not reported.

## Combs 2010

Methods	<p>Double-blind, randomised clinical trial.</p> <p>Multicentre, Obstetrix Collaborative Research Network, USA.</p>
Participants	<p>81 women randomised: 56 allocated to 17P and 25 to placebo.</p> <p>Inclusion criteria: mothers carrying trichorionic-triamniotic triplets – confirmed at 15-23 week detailed second-trimester ultrasound examination – showing normal amniotic fluid volume and no major fetal anomalies.</p> <p>Exclusion criteria: women with symptomatic uterine contractions, rupture of fetal membranes, any contraindication to interventions intended to prolong the pregnancy, a pre-existing medical condition that might be worsened by progesterone, or a pre-existing medical condition carrying a high risk of preterm delivery. Women less than 18 years of age, had an allergy to 17P or the oil vehicle, had taken any progesterone-derivative medication after 15 weeks of gestation, or had undergone placement of cervical cerclage for treatment of cervical change in the current pregnancy.</p>
Interventions	<p>Experimental intervention: 17 alpha-hydroxyprogesterone caproate (17P) (250 mg in 1 mL castor oil) – weekly injections starting at 16-22 weeks and continued until 34 weeks or delivery. Weekly repeat injections were carried out at the site or at home with partner administering after training. Injection diary for partner injections and measurement of unused medication returned by patient used to assess compliance with home administration.</p> <p>Control/Comparison intervention: identical appearing placebo (in 1 mL castor oil).</p>
Outcomes	<p>Primary outcomes: composite neonatal morbidity defined as 1 or more of: perinatal death (stillbirth, neonatal death, miscarriage); respiratory distress syndrome; use of oxygen therapy at 28 days of life; neonatal sepsis proven by blood culture; pneumonia; intraventricular haemorrhage (grade III or IV); periventricular leucomalacia; necrotising enterocolitis requiring surgery; retinopathy of prematurity; newborn asphyxia.</p> <p>Secondary outcomes: individual neonatal morbidities listed above; gestational age at delivery; birth-weight; maternal side effects.</p> <p>Other outcomes reported:</p> <p>Mean weeks of gestation.</p> <p>Delivery before 28, 32 or 35 week.</p> <p>Reason for delivery before 32 weeks (spontaneous; indicated).</p> <p>Reason for delivery, all deliveries (spontaneous; indicated).</p> <p>Caesarean delivery.</p> <p>Tocolysis used.</p> <p>Antenatal corticosteroids.</p> <p>Maternal complications:</p> <p>Pre-eclampsia or gestational hypertension.</p> <p>Gestational diabetes.</p> <p>Chorioamnionitis.</p> <p>Sepsis.</p>

**Combs 2010** (Continued)

Postpartum endometritis.

Neonatal outcomes:

Birthweight, g.

Head circumference, cm.

Total hospital stay, days.

NICU.

Intermediate care.

Notes

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer-generated scheme.
Allocation concealment (selection bias)	Low risk	Random-number generated centrally by pharmacy. "Progesterone or identical-appearing placebo was compounded by pharmacy and shipped in advance to each study site in coded prenumbered kits. To randomise the research nurse contacted the central pharmacy by telephone or fax to obtain the code number for the kit assigned to that patient."
Incomplete outcome data (attrition bias) All outcomes	Low risk	<p>248 women identified with triplets, 147 eligible for trial inclusion, of these 89 gave consent (61%) and were given trial injection. Of these, 81 (91%) returned for randomisation.</p> <p>No loss – 81 women randomised and outcome data available for all 81 mothers and 243 offspring.</p> <p>"Analysis was by the "intention-to-treat" principle. Accordingly, outcomes for each patient were tabulated according to the assigned group (17P vs placebo) regardless of her compliance."</p>
Selective reporting (reporting bias)	Low risk	Yes – all expected outcomes reported.
Other bias	Low risk	<p>Baseline characteristics of the participants were similar. There were no significant difference between the groups in the percentage with cervix length less than 2.5 cm 17% in the 17P group versus 35% in the placebo group or with positive fibronectin, 11% versus 9%.</p> <p>Mean compliance was 98.5% in the 17P group and 96.1% in the placebo group. There was no significant difference between groups in the percentage of injections given by clinic staff (27% versus 30%), by patients themselves (13% versus 15%), or by their designated representatives (61% versus 56%).</p> <p>Included multiple pregnancies (triplet) - adjustment made in analysis - used repeated measures model, where each infant was considered as a repeated measure.</p>
Blinding of participants and personnel (performance bias)	Low risk	"Subjects, physicians, and study personnel remained blinded as to group assignment until after completion of the trial."

**Combs 2010** (Continued)

All outcomes

Blinding of outcome assessment (detection bias) All outcomes	Low risk	“Data were abstracted by study personnel who remained blinded to each subject’s group assignment.”
---	----------	--

**Combs 2011**

Methods	Double-blind, randomised clinical trial.  Multicentre – 18 sites, Obstetrix Collaborative Research Network, USA.
---------	--

Participants	240 women randomised: 160 allocated to 17Pc and 80 to placebo.  Inclusion criteria: women were eligible if they had a dichorionic-diamniotic twin pregnancy at 15-23 weeks' gestation and if they had completed a detailed ultrasound examination – showing no major fetal anomalies.  Exclusion criteria: women were excluded if they were < 18 years old; had taken any progestins > 15 weeks of gestation; or had symptomatic uterine contractions, rupture of the fetal membranes, any contraindication to prolonging the pregnancy, any pre-existing condition that might be worsened by progesterone, or a pre-existing medical condition carrying a high risk of preterm delivery.
--------------	---

Interventions	Experimental intervention: 17 alpha-hydroxyprogesterone caproate (17P) (250 mg in 1 mL castor oil) – weekly injections starting at 16-24 weeks and continued until 34 weeks or delivery. Weekly repeat injections were carried out at the site or at home with partner administering after training. Injection diary for partner injections and measurement of unused medication returned by patient used to assess compliance with home administration.  Control/Comparison intervention: identical appearing placebo (in 1 mL castor oil).
---------------	--

Outcomes	Primary outcomes: composite neonatal morbidity defined as 1 or more of: perinatal death (stillbirth, neonatal death, miscarriage); respiratory distress syndrome; use of oxygen therapy at 28 days of life; neonatal sepsis proven by blood culture; pneumonia; intraventricular haemorrhage (grade III or IV); periventricular leucomalacia; necrotising enterocolitis requiring surgery; retinopathy of prematurity; newborn asphyxia.  Secondary outcomes: individual neonatal morbidities listed above; gestational age at delivery; birth-weight; maternal side effects.  Other outcomes reported:  Mean weeks of gestation.  Delivery before 28, 32 or 34 or 37 weeks.  Reason for delivery before 37 weeks (spontaneous; indicated).  Caesarean delivery.  Tocolysis used.  Antenatal corticosteroids.  Maternal complications:  Pre-eclampsia or gestational hypertension.

Notes

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer-generated scheme.
Allocation concealment (selection bias)	Low risk	Random-number generated centrally by pharmacy. "Progesterone or identical-appearing placebo was compounded by pharmacy and shipped in advance to each study site in coded prenumbered kits. To randomise the research nurse contacted the central pharmacy by telephone or fax to obtain the code number for the kit assigned to that patient."
Incomplete outcome data (attrition bias) All outcomes	Low risk	<p>1450 women identified with twin pregnancy, 254 eligible and consented and were given trial injection. Of these, 240 returned for randomisation.</p> <p>No loss in progesterone group – 160 women allocated, 160 mothers delivered and 320 perinates with known outcome. 80 women allocated to placebo – 2 lost to follow-up – 78 women delivered and 156 perinates with known outcome.</p> <p>"Outcomes for each patient were tabulated according to assigned group regardless of her compliance."</p>
Selective reporting (reporting bias)	Low risk	Yes – all expected outcomes reported.
Other bias	Low risk	Baseline characteristics of the subjects were similar.

**Combs 2011** (Continued)

Mean compliance was 96.4% in the 17P group and 98.7% in the placebo group.

Included multiple pregnancies (twin) - adjustment made in analysis - used repeated measures model, where each infant was considered as the repeated measure.

Blinding of participants and personnel (performance bias) All outcomes	Low risk	“Subjects, physicians, and study personnel remained blinded as to group assignment until after completion of the trial.”
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not reported.

**Combs 2011a**

Methods	<p>Double-blind, placebo-controlled randomised clinical trial.</p> <p>Multicentre – 18 sites, Obstetrix Collaborative Research Network, USA.</p>
Participants	<p>12 women randomised: 4 allocated to 17P and 8 to placebo. The trial was terminated early because of 2 separate issues related to the supply of 17P.</p> <p>Inclusion criteria: women were eligible if they were at least 18 years old, had a singleton pregnancy at 23.0 to 31.9 weeks of gestation and PROM.</p> <p>Exclusion criteria: women were excluded with contraindications to expectant management; with known fetal abnormalities; with history of allergy to 17P or castor oil; with medical conditions that might adversely interact with 17P; with medical conditions treated with systemic steroid medications; or with a cervical cerclage present at the time of PROM.</p>
Interventions	<p>Experimental intervention: 17 alpha-hydroxyprogesterone caproate (17P) (250 mg in 1 mL castor oil) – weekly intramuscular injections</p> <p>Control/Comparison intervention: identical appearing placebo (in 1 mL castor oil).</p>
Outcomes	<p>Primary outcomes: prolongation of pregnancy until favourable gestational age. Composite neonatal morbidity defined as 1 or more of: stillbirth, neonatal death, infant death before hospital discharge; respiratory distress syndrome; intracranial haemorrhage grade III or IV; necrotising enterocolitis stage 2 or 3; culture proven sepsis within 72 hours of birth; periventricular leucomalacia.</p> <p>Secondary outcomes: pregnancy prolongation (interval from randomisation to delivery). Individual neonatal morbidities listed above; gestational age at delivery; birthweight; maternal side effects.</p> <p>Other outcomes reported:</p> <p>Delivery at 34 weeks or more.</p> <p>Delivery at 32-33.9 weeks with documented fetal lung maturity.</p> <p>Mean gestational age at delivery.</p>

**Combs 2011a** (Continued)

Delivery before 32 or 34 weeks.  
 Pulmonary maturity testing.  
 Latency – randomisation to delivery.  
 Less than 1 week.  
 1.0 to 1.9 weeks.  
 2.0 2.0 weeks or more.  
 Reason for delivery before 34 weeks (spontaneous; chorioamnionitis; fetal indications).  
 Maternal complications:  
 Pre-eclampsia or gestational hypertension.  
 Gestational diabetes.  
 Chorioamnionitis.  
 Sepsis.  
 Caesarean delivery.  
 Tocolysis in first 48 hours.  
 Antenatal corticosteroids.  
 Neonatal outcomes:  
 Birthweight, g.  
 Total hospital stay, days.  
 NICU stay, days.  
 Newborns with congenital anomaly.  
 Adverse events not tabulated elsewhere.

Notes

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer-generated random number sequence was used by the trial statistician to generate a randomisation code.
Allocation concealment (selection bias)	Low risk	Random-number generated by a statistician and held centrally at each site's inpatient pharmacy.
Incomplete outcome data (attrition bias) All outcomes	Low risk	No loss to follow-up – but only 12 patients were randomised – 8 to placebo and 4 to 17P  Appears to have been ITT.
Selective reporting (reporting bias)	Low risk	Yes – all expected outcomes reported .
Other bias	Unclear risk	The trial was stopped early due to 2 separate issues related to the supply of 17P. Only 12 patients were randomised and because of the early termination,

**Combs 2011a** (Continued)

the trial was grossly under-powered to make conclusions as to the efficacy or safety of 17P in women with PROM.

Too few patients to assess baseline imbalance.

Blinding of participants and personnel (performance bias) All outcomes	Low risk	"Participants and research personnel were blinded to group assignment throughout."
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not reported.

**da Fonseca 2003**

Methods	Method of randomisation: random number table. Allocation concealment: sequential sealed envelopes; allocation to either drug A or B; allocation of groups revealed after last woman birthed. Blinded outcome assessment: yes. Completeness of follow-up: outcome data available for 142 women (15 women excluded after randomisation).
Participants	157 women considered to be at 'high risk' for preterm birth due to history of previous preterm birth, cervical suture, uterine malformation.
Interventions	Nightly intravaginal pessary of either 100 mg progesterone or placebo from 24 weeks until 28 weeks' gestation, or birth if earlier.
Outcomes	Preterm birth before 37 weeks' gestation; preterm birth before 34 weeks' gestation.
Notes	Trial conducted in Sao Paulo, Brazil.

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Random number table.
Allocation concealment (selection bias)	Low risk	Adequate; sequential sealed opaque envelopes.
Incomplete outcome data (attrition bias) All outcomes	Low risk	15 women (less than 1%) post-randomisation exclusions.
Selective reporting (reporting bias)	Low risk	The published report includes all expected outcomes (incidence of preterm delivery; frequency of uterine contractions).
Other bias	Low risk	"The two groups were found similar in regard to age, risk factors for preterm delivery, and obstetric history."

**da Fonseca 2003** (Continued)

Blinding of participants and personnel (performance bias) All outcomes	Low risk	Caregivers and participants blinded.
---	----------	--------------------------------------

Blinding of outcome assessment (detection bias) All outcomes	Low risk	Outcome assessor blinded.
---	----------	---------------------------

**Elsheikhah 2010**

Methods	Described as “randomized controlled study” in abstract title. Single centre, Cairo, Egypt.
---------	---

Participants	100 women: 50 allocated to progesterone group and 50 to placebo. Inclusion criteria: women with twin pregnancy. Exclusion criteria: patients with anomalies were excluded.
--------------	--

Interventions	Experimental intervention: vaginal progesterone 200 mg daily for 10 weeks from the 24 <sup>th</sup> to the 34 <sup>th</sup> week of gestation. Control/Comparison intervention: placebo for the same duration.
---------------	---

Outcomes	Mean cervical length. Mean gestational age at delivery. Fetal complications (not specified). NICU admissions.
----------	--

Notes

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Data limited – only reported as an abstract.
Allocation concealment (selection bias)	Unclear risk	Data limited – only reported as an abstract.
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	Data limited – only reported as an abstract.
Selective reporting (reporting bias)	Unclear risk	Data limited – only reported as an abstract.
Other bias	Unclear risk	Data limited – only reported as an abstract. Multiple pregnancies - no adjustment apparent from abstract report.

**Elsheikhah 2010** (Continued)

Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Data limited – only reported as an abstract.
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Data limited – only reported as an abstract.

**Facchinetti 2007**

Methods	Method of randomisation: random number table. Allocation concealment: randomisation list managed by senior midwife; allocation to either progesterone or placebo. Blinding of outcome assessment: no. Completeness of follow-up: outcome data available for 60 women.	
Participants	60 women presenting between 25 and 33 + 6 weeks' gestation with symptoms and signs of threatened preterm labour, where acute symptoms were arrested following use of tocolytic medication (atosiban).	
Interventions	341 mg intramuscular 17OHP administered every 4 days to 36 weeks' gestation.	
Outcomes	Cervical length as assessed by transvaginal ultrasound. Secondary outcomes included preterm birth < 37 weeks, and infant birthweight.	
Notes	Trial conducted in Modena, Italy.	

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Random number table.
Allocation concealment (selection bias)	Unclear risk	Unclear; list managed by "senior midwife" with allocation to either progesterone or placebo.
Incomplete outcome data (attrition bias) All outcomes	Low risk	Outcome data available for all women.
Selective reporting (reporting bias)	High risk	Cervical length was measured by transvaginal ultrasound scanning at discharge and at day 7 and 21. Results for cervical length at discharge were not fully reported. All other outcomes appear to have been reported upon (cervical length at 7 and 21 days; preterm delivery < 37 weeks and < 35 weeks; birthweight).
Other bias	Low risk	No differences were found between the 2 groups for baseline characteristics (see table, page 3).
Blinding of participants and personnel (performance bias) All outcomes	High risk	No blinding - not possible "The study was not double blind because it was not sponsored; therefore, the preparation of true placebo (same vial, same oil without active compound) was not possible."

**Facchinetti 2007** (Continued)

Blinding of outcome assessment (detection bias) All outcomes	High risk	No blinding of outcome assessor.
---	-----------	----------------------------------

**Fonseca 2007**

Methods	Method of randomisation: not stated. Allocation concealment: central randomisation process; identically appearing treatment packs. Blinded outcome assessment: yes. Completeness of follow-up: outcome data available for all 250 women randomised.
Participants	250 women undergoing transvaginal ultrasound assessment of cervical length, where the cervical length was measured to be 15 mm or less. Women with both singleton and multiple pregnancies were eligible to participate (226 singleton and 24 with twin pregnancies).
Interventions	Nightly intravaginal pessary of either 200 mg micronised progesterone or placebo from 24 weeks until 33 + 6 weeks' gestation, or birth if earlier.
Outcomes	Primary outcome: spontaneous preterm birth less than 34 weeks' gestation. Secondary outcomes: infant birthweight, fetal death, neonatal death, major adverse outcomes (intra-ventricular haemorrhage, respiratory distress syndrome, retinopathy of prematurity, necrotising enterocolitis), need for neonatal special care (NICU, ventilation, phototherapy, treatment for proven or suspected sepsis, blood transfusion).
Notes	Trial conducted in 5 maternity hospitals in London (UK), Santiago (Chile), Sao Paulo (Brazil), and Greece.  This data analysed in subgroup of women with short cervix - multiples only made up a small proportion of total group.

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Method of randomisation generation not stated.
Allocation concealment (selection bias)	Low risk	Adequate; central randomisation; identical appearing treatment packs.
Incomplete outcome data (attrition bias) All outcomes	Low risk	Complete follow-up.
Selective reporting (reporting bias)	Low risk	All expected outcomes are reported (spontaneous delivery before 34 completed weeks; birthweight; fetal or neonatal death; major adverse outcomes before discharge; need for neonatal special care).
Other bias	Low risk	"There were no significant differences in baseline characteristics between the placebo and progesterone groups" (see Table 1, page 465).  Singleton and twin pregnancies - adjustment made for infant outcomes, "the analyses of infant outcomes used robust standard errors and were clustered on a maternal identifier to account for the non-independence of twin pairs."

**Fonseca 2007** (Continued)

Blinding of participants and personnel (performance bias) All outcomes	Low risk	Blinding of participants, caregivers, outcome assessors.
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Blinding of participants, caregivers, outcome assessors.

**Glover 2011**

Methods	Pilot, single-centre, randomised, double-blind, placebo-controlled trial.  Single centre, Miami Valley Hospital, Ohio, USA.	
Participants	Inclusion criteria: women < 20 weeks' gestation and had at least 1 prior spontaneous preterm birth of a live-born singleton infant between 20 <sup>0/7</sup> weeks and 36 <sup>6/7</sup> weeks' gestation.  Exclusion criteria: multiple gestations, the presence of major fetal anomalies, progesterone use in current pregnancy, the presence of a cervical cerclage and the presence of a placenta previa.	
Interventions	36 women randomised: 20 allocated to progesterone group and 16 allocated to placebo group.  Experimental intervention: 400 mg (2 200-mg capsules) of oral micronized progesterone MP. Administration of the tablets was initiated between 16 <sup>0/7</sup> and 19 <sup>6/7</sup> weeks and was continued until the completion of the 33 <sup>rd</sup> week of gestation.  Control/Comparison intervention: control group took 2 identical placebo capsules for the same time period.	
Outcomes	Rate of recurrent spontaneous preterm birth.  Serum progesterone levels.  Neonatal morbidity and mortality: birthweight (g) mean (SD); male gender; 5-minute Apgar (mean); ventilator use; neonatal length of stay (mean), days.	

Notes

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"Randomization was done by the hospital's research pharmacy using a standard randomization table methodology for two groups."

**Glover 2011** (Continued)

Allocation concealment (selection bias)	Low risk	Central allocation – pharmacy controlled: “After subjects were randomized to their respective group, the research pharmacy dispensed a 1-month supply of either progesterone or placebo tablets in identical prescription bottles, which were labelled identically as “progesterone study medication.”
Incomplete outcome data (attrition bias) All outcomes	Low risk	<p>45 patients were eligible for randomisation – 9 women didn't complete the initial evaluation or failed to present to the pharmacy for randomisation and were excluded.</p> <p>Appears that 36 were randomised, but only 33 analysed. 3 more participants were excluded – 1 from the MP group as became apparent that she had not had previous spontaneous preterm birth as she had been induced for severe eclampsia; 1 from the placebo group had a spontaneous abortion at 14 weeks; and another from placebo group did not complete her prenatal care at this centre and delivered elsewhere.</p> <p>3 appear to have been excluded after randomisation, see above.</p> <p>Analysis appears to be ITT: 2 women ended their participation in the study – but both delivered at this institution and were included in their respective group for all analyses.</p>
Selective reporting (reporting bias)	Unclear risk	In methods reports that neonatal mortality will be reported – but was not reported.
Other bias	Low risk	Similar baseline characteristics – no statistically significant differences between groups.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	“The study subjects’ physicians were aware of the study participation but were blinded to the group assignment.”
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not reported.

**Grobman 2012**

Methods	Multicentre, randomised controlled trial.  Multicentre, Maternal-Fetal Units Network, USA.
Participants	<p>657 women recruited between April 2007 and May 2011 in various centres in the USA</p> <p>657 women randomised: 327 to OHPc group and 330 to placebo.</p> <p>Inclusion criteria: nulliparous women with a singleton gestation between 16 and 22 3/7 weeks with cervical length less than 30 mm.</p>

**Grobman 2012** (Continued)

Exclusion criteria: Women that had selective fetal reduction for multiple pregnancy, had evidence of additional fetal pole/embryo at 12 weeks or more, vaginal bleeding, prolapsed membranes, major fetal anomaly, current or planned cerclage, maternal medical condition associated with preterm delivery (e.g. hypertension) prior cervical surgery, or planned preterm delivery.

Interventions	Experimental intervention: 250 mg IM weekly 17 alpha hydroxyprogesterone caproate (17-OHPc) given by nurse until delivery or up to 36 weeks and 6 days gestation.  Control/Comparison intervention: An identical appearing placebo. Weekly IM injections of placebo (castor oil) given by study nurse until delivery or up to 36 weeks and 6 days gestation.
---------------	--

Outcomes	Maternal outcomes:  Preterm birth before 37 weeks  Birth before 35 weeks  Preterm rupture of membranes  Delivery < 28 weeks  Tocolytic therapy  Caesarean delivery  Side effects (any; injection site; urticaria; nausea)   Perinatal outcomes:  Fetal death  Neonatal death  Respiratory distress syndrome  Necrotising enterocolitis grade II or III  Intraventricular haemorrhage grade II or IV  Periventricular leucomalacia  Early-onset sepsis  Retinopathy of prematurity grade III or IV  Birthweight < 2500 g  5-minute Apgar < 7  NICU admission  Length of NICU stay, days
----------	---

Notes

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Data co-ordinating centre to created the computer-generated randomisation sequence. Simple turn method of randomisation used.

### Grobman 2012 (Continued)

Allocation concealment (selection bias)	Low risk	Simple randomisation method stratified by centre. Study treatments were re-search pharmacy prepared.
Incomplete outcome data (attrition bias) All outcomes	Low risk	All women randomised were accounted for in the analysis. Discontinuation of treatment was greater in the placebo group 33/330 vs 18/327 but there was an ITT analysis.
Selective reporting (reporting bias)	Low risk	All expected outcomes reported upon.
Other bias	Unclear risk	Groups appeared balanced at baseline (slightly more white Hispanic in the placebo group and this group were slightly younger). The study was stopped early as the study monitoring committee decided that further recruitment after data for 591 available for interim analysis would be unlikely to show benefit (planned 1000 women , data for 657).
Blinding of participants and personnel (performance bias) All outcomes	Low risk	It was stated that neither patients nor medical staff were aware of treatment group and the study was placebo controlled. It was stated that the IM injections appeared identical.
Blinding of outcome assessment (detection bias) All outcomes	Low risk	It was stated that the trial was blinded to research staff collecting outcome data. The trial was placebo controlled.

### Hartikainen 1980

Methods	Method of randomisation: stated to be "placebo controlled and double blind". Allocation concealment: not stated. Blinded outcome assessment: yes. Completeness of follow-up: outcome data available for 77 women.	
Participants	77 women with a twin pregnancy.	
Interventions	Weekly intramuscular injection of either 250 mg 17-hydroxyprogesterone caproate or placebo from 28 weeks' gestation until 37 weeks' gestation or birth if earlier.	
Outcomes	Perinatal death.	
Notes	Trial conducted in Finland.	

#### **Risk of bias**

<b>Bias</b>	<b>Authors' judgement</b>	<b>Support for judgement</b>
Random sequence generation (selection bias)	Unclear risk	Process of sequence generation not stated.
Allocation concealment (selection bias)	Unclear risk	Unclear.
Incomplete outcome data (attrition bias) All outcomes	Low risk	Outcome data available for all participants.

**Hartikainen 1980** (Continued)

Selective reporting (reporting bias)	Low risk	All expected outcomes are reported (duration of pregnancy; spontaneous delivery before 37 weeks; weights of neonates; perinatal mortality; neonatal morbidity (respiratory problems; omphalitis; pulmonary infection); maternal levels of progesterone; estradiol).
Other bias	Unclear risk	"The gestational age at the onset of medication, the gestational age at diagnosis of twin pregnancy and the patient's age were similar in both groups." (see table 1, page 693).  "The factors commonly regarded as risk factors for premature delivery showed no differences between groups." (see table 2, page 693).  Multiple pregnancies - abstract only available - limited data - no adjustment apparent.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Caregivers and participants blinded.
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Blinding of outcome assessors.

**Hassan 2011**

Methods	Multicentre randomised double-blind placebo-controlled trial.  Multicentre - 44 centres in 10 countries, USA.
Participants	465 women randomised: 236 allocated to progesterone and 229 to placebo.  Inclusion criteria: singleton gestation; gestational age between 19 + 0 and 23 + 6 weeks; transvaginal sonographic cervical length between 10 and 20 mm; without signs and symptoms of preterm labour.  Exclusion criteria: planned cerclage; acute cervical dilation; allergic reaction to progesterone; current or recent progestogen treatment within 4 weeks; chronic medical conditions that would interfere with study participation or evaluation of the treatment; major fetal anomaly or known chromosomal abnormality; uterine anatomic malformation; vaginal bleeding; known or suspected clinical chorioamnionitis.
Interventions	Experimental intervention: daily micronised vaginal progesterone gel - women self-administered the study drug once daily in the morning. Each applicator delivered 1.125 g gel containing 90 mg progesterone.  Control/Comparison intervention: an identical appearing placebo - each applicator delivered 1.125 g gel containing 90 mg placebo.
Outcomes	Primary outcome: preterm birth before 33 weeks.  Secondary outcomes: neonatal morbidity - respiratory distress syndrome; bronchopulmonary dysplasia; intraventricular haemorrhage grade III or IV; periventricular leucomalacia; proven sepsis; necrotising enterocolitis; perinatal mortality (fetal death or neonatal death) - composite scores were used to assess perinatal mortality and morbidity.

**Hassan 2011** (Continued)

Notes

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Randomisation allocation was 1:1 and was accomplished using a centralised interactive voice response system. Randomisation was stratified according to centre and risk strata (previous preterm birth between 20 and 35 weeks or no previous preterm birth) using a permuted blocks strategy with a block size of 4.
Allocation concealment (selection bias)	Low risk	Reported that allocation concealment accomplished in 3 ways: 1. participant study kits at each site were numbered independently from the treatment assignments in the randomisation blocks; 2. IVR system specified which kit number was to be dispensed to the subject; 3. the study drug packaging , applicators and contents were identical in appearance.
Incomplete outcome data (attrition bias) All outcomes	Low risk	733 women eligible, 268 declined, 465 randomised.  1 lost to follow-up from progesterone group and 6 from placebo group.  ITT analysis performed.
Selective reporting (reporting bias)	Low risk	All expected outcomes reported upon.
Other bias	Low risk	Baseline characteristics were similar between groups.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Described as double blind.
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not reported.

**Hauth 1983**

Methods	Method of randomisation: stated to be "randomised, double blind intervention". Allocation concealment: not stated. Blinded outcome assessment: yes. Completeness of follow-up: outcome data available for all women randomised.
Participants	168 women on active military duty.
Interventions	Weekly intramuscular injection of either 1000 mg 17-hydroxyprogesterone caproate or placebo from 16 to 20 weeks until 36 weeks' gestation, or birth if earlier.
Outcomes	Preterm birth before 37 weeks' gestation; birthweight less than 2.5 kg; perinatal death.

**Hauth 1983** (Continued)

Notes Trial conducted in Lackland Airforce Base, Texas, USA.

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Sequence generation not stated.
Allocation concealment (selection bias)	Unclear risk	Unclear.
Incomplete outcome data (attrition bias) All outcomes	Low risk	Outcome data available for all women recruited.
Selective reporting (reporting bias)	Low risk	All expected outcomes were reported (low birthweight; perinatal mortality; pregnancy-induced hypertension; premature labour).
Other bias	Low risk	The groups were similar for parity, previous abortion, race, cigarette smoking, and marital status.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Caregivers and participants blinded.
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Blinding of outcome assessors.

**Ibrahim 2010**

Methods	Randomised placebo-controlled trial.  Ain Shams University Maternity Hospital, Cairo, Egypt.
Participants	50 women randomised: 25 allocated to progesterone group and 25 to placebo group.  Inclusion criteria: singleton pregnant women in their second trimester with a history of preterm labour.  Exclusion criteria: women with a history medical disease during pregnancy, multiple pregnancy, abdominal or cervical cerclage, known fetal anomalies or scarred uterus.
Interventions	Experimental intervention: 17- $\alpha$ -hydroxy progesterone caproate – 1 dose of 250 mg intramuscular progesterone- weekly until 36 weeks.  Control/Comparison intervention: standard dose of placebo IM per week until 36 weeks.
Outcomes	Mean gestation age.  Birth < 37 weeks.  Birth > 37 weeks.  Live neonates.  Need for NICU.

**Ibrahim 2010** (Continued)

Neonatal death.  
 Birthweight < 2500 g.  
 Birthweight > 2500 g.  
 Apgar score < 7.  
 Apgar score > 7.

Notes

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Not reported – says women were divided into 2 groups –but no details of method of randomisation.
Allocation concealment (selection bias)	Unclear risk	“Randomisation was done by the use of sealed envelopes which were opened by the nurse responsible for giving the injections to all participants whether Cidolut depot or placebo” – unclear whether the envelopes were opaque and sequentially numbered – so nurse may have been able to foresee assignment.
Incomplete outcome data (attrition bias) All outcomes	Low risk	All women appear to be included in the results – 25 in each group.
Selective reporting (reporting bias)	Low risk	All expected outcomes reported upon.
Other bias	Unclear risk	Baseline demographic characteristics not fully reported.
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Described as double blind – but no details described.
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not reported.

**Johnson 1975**

Methods	Method of randomisation: stated to be "random double blind fashion". Allocation concealment: next of identical drug packages. Blinded outcome assessment: yes. Completeness of follow-up: outcome data available for 43 women (7 women excluded after randomisation).
Participants	50 women with a history of 2 previous spontaneous abortions or previous preterm birth before 36 weeks' gestation.
Interventions	Weekly intramuscular injection of either 250 mg 17-hydroxyprogesterone caproate or placebo from 'booking' until 24 weeks' gestation.
Outcomes	Preterm birth before 37 weeks' gestation; birthweight less than 2.5 kg; perinatal death.

**Johnson 1975** (Continued)

Notes Trial conducted in Baltimore, USA.

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Generation of sequence not stated.
Allocation concealment (selection bias)	Low risk	Adequate; identical appearing treatment packs.
Incomplete outcome data (attrition bias) All outcomes	Low risk	7 women excluded post-randomisation (1%).
Selective reporting (reporting bias)	Low risk	All expected outcomes reported (premature delivery; birthweight; perinatal mortality).
Other bias	Low risk	Groups were similar for baseline characteristics, (see table 2, page 678), although placebo group included fewer smokers and less heavy smokers than progesterone group.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Caregivers and participants blinded.
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Outcome assessors blinded.

**Lim 2011**

Methods	Multicentre, double-blind, placebo-controlled randomised trial.  Multicentre, 55 obstetric clinics in Netherland.
Participants	671 women randomised: 336 allocated to progesterone and 326 allocated to placebo.  Inclusion criteria: women with a multiple pregnancy and gestational age between 15 and 19 weeks.  Exclusion criteria: women with a previous spontaneous preterm birth before 34 weeks, serious congenital defects or death of 1 or more fetuses, early signs of twin-to-twin transfusion syndrome, or primary cerclage were excluded from participation.
Interventions	Experimental intervention: 1 mL 17- $\alpha$ -hydroxyprogesterone caproate (250 mg/mL in castor oil) – starting between 16 and 20 weeks and continuing to 36 weeks. Injections were administered at the clinic, by a general practitioner or, in case the patient or a family member had a background in medical practice, at the patient's home.  Control/Comparison intervention: 1 mL placebo (castor oil) – study medication and placebo were identical in packaging, colour and consistency.
Outcomes	Primary outcomes: composite adverse neonatal outcome – severe respiratory distress syndrome; bronchopulmonary dysplasia; intraventricular haemorrhage grade II B or worse; necrotising enterocolitis; proven sepsis; death before discharge.

Lim 2011 (Continued)

Secondary outcomes:

Side effects (soreness, itching, and swelling).

Gestational age at delivery.

Preterm birth before 28, 32 and 37 weeks.

Length of admission to the NICU.

Maternal morbidity.

Hospitalisation of the mother due to (threatened) preterm labour.

Costs.

Notes

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"An independent data manager rendered a computer-generated list that was stratified by chorionicity, parity, and number of multiples, using random blocks of maximum block size."
Allocation concealment (selection bias)	Low risk	Web-based randomisation – "Randomization was accessible through a website" and "Allocation code was known only to ACE Pharmaceuticals"
Incomplete outcome data (attrition bias) All outcomes	Low risk	1865 women eligible, 1194 declined participation, 671 women entered trial.  336 randomised to progesterone group and no women lost to follow-up/326 randomised to placebo and 4 lost to follow-up.  681 children born to 336 women in progesterone group/ 680 children born to 331 women in placebo group.  Neonatal outcome available for 681 in progesterone group and 674 in placebo group.  States that "all analyses were based on the intention-to-treat principle."
Selective reporting (reporting bias)	Low risk	All expected outcomes reported upon.
Other bias	Low risk	Baseline characteristics similar.  Multiple pregnancies (twin, triplet and 1 quadruplet) - adjustments made for all neonatal, delivery, pregnancy and side effect outcomes.
Blinding of participants and personnel (performance bias)	Low risk	"Participants, caregivers, and data collectors were all blinded to allocation."

**Lim 2011** (Continued)

All outcomes

Blinding of outcome assessment (detection bias) All outcomes	Low risk	Participants, caregivers, and data collectors were all blinded to allocation.”
---	----------	--

**Majhi 2009**

Methods	Prospective randomised trial.  Department of Obstetrics and Gynaecology, Postgraduate Institute of Medical Education and Research (PGIMER), Chandigarh, India.
Participants	50 women randomised: 50 allocated to progesterone and 50 allocated to no treatment.  Inclusion criteria: women at high risk for preterm birth, having a singleton pregnancy and current gestation 16-24 weeks. High risk was defined by history of at least once prior spontaneous preterm birth of a singleton infant > 20 and < 37 weeks due to spontaneous labour or preterm rupture of fetal membranes.  Exclusion criteria: women with multifetal gestation, congenital malformation in the fetus, current or planned cervical cerclage or with any associated medical disorder were excluded.
Interventions	Experimental intervention: 100 mg natural micronised progesterone capsule intravaginally once daily at bedtime from 20-24 weeks' gestation until 36 weeks.  Control/Comparison intervention: no placebo – just managed according to the institute protocol.
Outcomes	Primary outcomes:  Preterm birth < 37 weeks.  Preterm birth ≤ 34 weeks.  Secondary outcomes:  Maternal hospitalisation.  Vaginal delivery.  LSCS.  Birthweight (Mean SD).  NICU.  Sepsis.  Hyperbilirubinaemia.  Necrotising enterocolitis.  Cord pH (Mean SD).

Notes

**Risk of bias**

**Majhi 2009** (Continued)

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer-generated random-number tables.
Allocation concealment (selection bias)	Low risk	Sequentially numbered opaque sealed envelopes – provided centrally by Dept Biostatistics and investigators were not involved in the randomisation procedure.
Incomplete outcome data (attrition bias) All outcomes	Low risk	118 women met the inclusion criteria; 100 women consented and were included – 50 assigned to each group.  There was no attrition during follow-up.
Selective reporting (reporting bias)	Low risk	All expected outcomes reported upon.
Other bias	Unclear risk	Both groups were similar in all characteristics except BV, which was commoner in the study group. It was treated in both groups.
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Not reported – no placebo used though – so participants would have been aware of assignment.
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not reported.

**Meis 2003**

Methods	Method of randomisation: computer-generated 2:1 random number schedule. Allocation concealment: next of identical drug packages. Blinded outcome assessment: yes. Completeness of follow-up: outcome data available for 463 women.
Participants	463 women with a history of previous spontaneous preterm birth; exclusion women with multiple pregnancy, known fetal anomaly, progesterone or heparin treatment during pregnancy, current or planned cervical cerclage, hypertension, seizure disorder.
Interventions	Weekly intramuscular injection of either 250 mg 17-hydroxyprogesterone caproate or placebo from 16 to 20 weeks until 36 weeks' gestation, or birth if earlier.
Outcomes	Preterm birth before 37 weeks' gestation; birthweight less than 2.5 kg; stillbirth; neonatal death; intraventricular haemorrhage; respiratory distress syndrome; bronchopulmonary dysplasia; sepsis; necrotising enterocolitis; retinopathy of prematurity; patent ductus arteriosus.
Notes	Trial conducted by the Maternal-Fetal Medicine Network, USA.

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer-generated sequence.

**Meis 2003** (Continued)

Allocation concealment (selection bias)	Low risk	Adequate; identical appearing treatment packs.
Incomplete outcome data (attrition bias) All outcomes	Low risk	Outcome data available for all 463 women recruited.
Selective reporting (reporting bias)	Low risk	All expected outcomes reported (preterm delivery < 37, < 35, < 32 weeks; pregnancy outcomes (e.g. caesarean delivery; chorioamnionitis; fetal and neonatal outcomes (e.g. birthweight; neonatal death; ventilatory support; necrotizing enterocolitis; proven sepsis).
Other bias	Low risk	Groups were similar for baseline characteristics, (see table 1, page 2382), although the women in the placebo group had had more previous preterm deliveries.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Women, caregivers and outcome assessors blinded.
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Women, caregivers and outcome assessors blinded.

**Moghtadaei 2008**

Methods	Randomised, double-blind, placebo-controlled trial.  Single site, Iran.
Participants	260 women randomised to treatment - number randomised to placebo not reported.  Inclusion criteria: women in advanced maternal age – primiparous aged 35 years or more.  Exclusion criteria: not reported.
Interventions	Experimental intervention: weekly injections of 17P (250 mg) starting at 16-20 weeks' gestation until 34 weeks.  Control/Comparison intervention: matching placebo.
Outcomes	Delivery before 37 weeks.  Delivery before 35 weeks.  Delivery before 32 weeks.  Hypertension.  Diabetes.  Intrauterine growth restriction.  Side effects at injection site.
Notes

**Norman 2009**

Methods	<p>Double-blind randomised placebo-controlled trial.</p> <p>Multicentre, 9 UK NHS hospitals – STOPPIT study (Study Of Progesterone for the Prevention of Preterm Birth In Twins), UK.</p>
Participants	<p>500 women randomised: 250 allocated to progesterone and 250 allocated to placebo.</p> <p>Inclusion criteria: women with twin pregnancy, with gestation and chorionicity established by scan before 20 weeks' gestation and attending the antenatal clinic during the recruitment period.</p> <p>Exclusion criteria: pregnancy complicated by a recognised structural or chromosomal fetal abnormality at the time of recruitment, or if they had contraindications to progesterone, planned cervical suture, planned elective delivery before 34 weeks' gestation, or planned intervention for twin-to-twin transfusion before 22 weeks' gestation. Women with higher multiple pregnancy were also excluded.</p>
Interventions	<p>Experimental intervention: daily vaginal progesterone gel 90 mg starting at 24 weeks and 0 days of gestation. Each applicator of intervention contained 1.45 g of gel and delivered 1.125 g of gel containing 8% progesterone</p> <p>Control/Comparison intervention: placebo gel – administered in the same way as active treatment, daily from 24 weeks' gestation. Each applicator of intervention contained 1.45 g of gel and delivered 1.125 g of gel containing 8% excipients.</p>
Outcomes	<p>Primary:</p> <p>Delivery or intrauterine death before 34 weeks.</p>

**Norman 2009** (Continued)

Secondary:

Gestation at delivery.

Mode of delivery.

Duration of each stage of labour.

Safety outcomes:

Admission to neonatal unit.

Duration of neonatal unit stay.

Mother died.

Intrauterine death.

Neonatal death.

Involved or prolonged inpatient maternal hospital admission.

Involved persistent/significant maternal disability or incapacity.

Life threatening.

Chorioamnionitis or intrauterine infection.

Congenital anomaly or birth defect.

Maternal symptoms.

Maternal satisfaction.

Notes

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"We used a randomisation schedule with permuted blocks of randomly mixed sizes to make up treatment packs (either active or placebo) for every patient, which were held in individual hospital pharmacies until use."
Allocation concealment (selection bias)	Low risk	Central allocation from research network – local researcher telephoned the interactive voice response randomisation application at the UK Clinical Research Network registered trials unit to be given a participant number that corresponded to a specific treatment pack.
Incomplete outcome data (attrition bias) All outcomes	Low risk	1483 assessed for eligibility, 983 excluded (did not meet eligibility; declined participation), 500 enrolled and randomised.  250 randomised to each group, 3 lost to follow-up from both treatment and control groups (6 altogether) – because of withdrawal of consent or not traceable after moving out of study area. 3 therefore excluded from each analysis.  Analysis was by ITT. 494 mothers and 988 babies remained for the per-protocol analysis.
Selective reporting (reporting bias)	Low risk	All expected outcomes appear to have been reported.

**Norman 2009** (Continued)

Other bias	Low risk	Baseline characteristics similar.  Multiple pregnancies - adjustment for some neonatal outcomes – give Odds Ratios: admission to neonatal unit;  duration of neonatal unit stay.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	“All study personnel and participants were masked to treatment assignment for the duration of the study.”
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not reported.

**O'Brien 2007**

Methods	Method of randomisation: random number table. Allocation concealment: identical appearing sequentially numbered treatment packs. Blinded outcome assessment: yes. Completeness of follow-up: outcome data available for 611 of 659 women randomised (48 (7.3%) women lost to follow-up).
Participants	659 women with a history of prior spontaneous preterm birth. Exclusions: adverse reaction to progesterone; progesterone treatment within 4 weeks of randomisation; medical conditions; suspected genital tract malignancy; thromboembolic disease; fetal anomaly; multiple pregnancy; planned cervical cerclage.
Interventions	Nightly vaginal progesterone gel (90 mg) versus placebo.
Outcomes	Preterm birth less than 32 weeks; Apgar scores, infant birthweight, NICU admission.  Secondary analysis of data from O'Brien 2012: infant weight, length and head circumference at 6, 12 and 24 months.
Notes	Trial conducted in 53 centres worldwide.

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Random number table.
Allocation concealment (selection bias)	Low risk	Adequate; identical appearing treatment packs.
Incomplete outcome data (attrition bias) All outcomes	Low risk	Outcome data available for 611 of 659 women randomised (7.3% women lost to follow-up).
Selective reporting (reporting bias)	Low risk	All expected outcomes reported (preterm birth; maternal, fetal and neonatal outcomes), detailed in table 2, page 692.
Other bias	Low risk	Baseline characteristics similar between groups (see table 1, page 691).

**O'Brien 2007** (Continued)

Blinding of participants and personnel (performance bias) All outcomes	Low risk	Women, caregivers and outcome assessors blinded.
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Women, caregivers and outcome assessors blinded.

**Papiernik 1970**

Methods	Method of randomisation: unclear. Allocation concealment: unclear. Blinded outcome assessment: yes. Completeness of follow-up: outcome data available for 99 women.
Participants	99 women with a "high preterm risk score".
Interventions	Every 3 days intramuscular injection of either 250 mg 17-hydroxyprogesterone caproate or placebo from 28 weeks' gestation until 32 weeks' gestation.
Outcomes	Preterm birth before 37 weeks' gestation; birthweight less than 2.5 kg; perinatal death.
Notes	Trial conducted in Paris, France.

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Not reported.
Allocation concealment (selection bias)	Unclear risk	Unclear.
Incomplete outcome data (attrition bias) All outcomes	Low risk	Outcome data available for 99 women randomised.
Selective reporting (reporting bias)	Unclear risk	Not possible to tell from translation.
Other bias	Low risk	From the translation of the paper "Each group studied was similar in age, the number of previous pregnancies, the onset of treatment and risk of preterm birth".
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Caregivers and participants blinded.
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Outcome assessor blinded.

## Rai 2009

Methods	<p>Randomised, double-blind, placebo-controlled trial.</p> <p>Single centre, Dept Obstetrics &amp; Gynaecology, University College of Medical Science and Guru Teg Bahadur Hospital, Delhi.</p>
Participants	<p>150 women randomised: 75 allocated to progesterone and 75 allocated to placebo.</p> <p>Inclusion criteria: asymptomatic women aged between 18 and 35 years who were between 18 and 24 weeks of pregnancy, with a history of at least 1 spontaneous preterm delivery (between 20 weeks and 36 weeks plus 6 days) and with a singleton live pregnancy.</p> <p>Exclusion criteria: women with first trimester bleeding, PROM, multiple pregnancy, fetal anomalies or active liver disease were excluded.</p>
Interventions	<p>Experimental intervention: 100 mg oral micronised progesterone – twice a day from recruitment (18-24 weeks) until 36 weeks or delivery.</p> <p>Control/Comparison intervention: placebo - twice a day from recruitment (18-24 weeks) until 36 weeks or delivery.</p>
Outcomes	<p>Primary:</p> <p>Mean prolongation of pregnancy in weeks and days of gestation.</p> <p>Gestational age at delivery:</p> <p>&lt; 28.</p> <p>28-31 + 6.</p> <p>32-33 + 6.</p> <p>34-36 + 6.</p> <p>Secondary:</p> <p>Use of tocolysis.</p> <p>Adverse drug effects.</p> <p>Neonatal outcomes:</p> <p>Neonatal age at delivery, week.</p> <p>Birthweight, g.</p> <p>NICU stay.</p> <p>&lt; 24 hours.</p> <p>24 hours – 1 week.</p> <p>&gt; 1 week.</p> <p>Apgar score at 1 minute.</p> <p>&lt; 6.</p>

Notes

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	“computer-generated numbers table.”
Allocation concealment (selection bias)	Low risk	Central allocation suggested - random number table provided by the Department of Biostatistics.
Incomplete outcome data (attrition bias) All outcomes	Low risk	150 assessed for eligibility, all enrolled and randomised.  75 randomised to each group – and 1 lost to follow-up from each group – 74 analysed in each group.  ITT not mentioned – but 74 from each group analysed.
Selective reporting (reporting bias)	Low risk	All expected outcomes appear to have been reported .
Other bias	Low risk	Baseline characteristics similar.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	“The patients and the medical staff were blinded to the study medication allocation until after the last patient had delivered and the study was complete.”
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not reported.

**Rode 2011**

Methods Randomised, double-blind, placebo-controlled trial.

**Rode 2011** (Continued)

Multicentre, 17 centres in Denmark and Austria.

**Participants**

677 women were randomised: 334 allocated to progesterone and 343 allocated to placebo

Inclusion criteria: women with a live, diamniotic twin pregnancy and chorionicity assessed by ultrasound before 16 weeks' gestation were eligible for recruitment.

Exclusion criteria: age < 18 years; known allergy to progesterone or peanuts (active treatment contained peanuts); history of hormone-associated thromboembolic disorders; rupture of membranes; treatment for or signs of twin-to-twin transfusion syndrome; intentional fetal reduction; known major structural or chromosomal fetal abnormality; known or suspected malignancy in genitals or breasts; known liver disease; women with higher-order multiple pregnancies; women who did not speak and understand Danish or German.

**Interventions**

Experimental intervention: vaginal micronized progesterone pessaries (200 mg) – self-administered daily by participants – starting from 20-24 weeks until 34 weeks' gestation.

Control/Comparison intervention: vaginal placebo pessaries (200 mg) – self-administered daily by participants – starting from 20-24 weeks until 34 weeks' gestation.

**Outcomes**

Primary:

Incidence of delivery before 34 + 0 weeks' gestation.

Secondary:

Delivery before 22, 28, 32, 37 weeks' gestation.

Delivery by caesarean section (emergency and planned).

Number of liveborn infants.

Miscarriage.

Intrauterine death.

Infant death during delivery.

Neonatal death.

Death after 28 days.

Sudden infant death.

Corticosteroids for fetal lung maturation.

Tocolytic therapy.

Maternal adverse outcomes (gestational diabetes; increased liver enzymes; pre-eclampsia; thromboembolic event).

Birthweight < 2500 g.

Birthweight < 1500 g.

Apgar score < 7 at 5 minutes.

Congenital or chromosomal anomalies.

Perinatal complication:

Hypoglycaemia.

**Rode 2011** (Continued)

Intraventricular haemorrhage.

Jaundice.

Necrotising enterocolitis.

Patent ductus arteriosus.

Respiratory distress syndrome.

Retinopathy of prematurity.

Septicemia.

Admission to NICU.

CPAP treatment of at least 24 hours.

Respirator treatment.

Neurophysiological development 6 and 18 months after estimated date of delivery (assessed via Ages and Stages Questionnaire (ASQ)).

Notes

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"The Perinatal Epidemiology Research Unit created a randomization sequence with a 1:1 ratio."
Allocation concealment (selection bias)	Low risk	<p>Central allocation suggested - used an interactive voice-response randomisation system:</p> <p>"We stratified by center and chorionicity using an interactive voice-response randomization system at the Perinatal Epidemiology Research Unit. Each local researcher telephoned the randomization system, was given a randomization number that corresponded to a specific treatment box from a given batch".</p>
Incomplete outcome data (attrition bias) All outcomes	Low risk	<p>1507 assessed for eligibility, 219 excluded, 1288 informed about the trial, 526 declined to participate/did not answer, 677 randomised - 343 to each group.</p> <p>2 from placebo group lost to follow-up - 343 included in analysis for progesterone group and 341 in placebo group.</p> <p>9 women in the progesterone group and 4 in the placebo group never started treatment because they changed their minds with respect to participation (n = 8), they miscarried or a fetus died in utero (n = 2) or they were withdrawn from the study (n = 3). Analyses based on 343 from progesterone group and 341 from placebo group.</p> <p>States that all analyses were performed according to the ITT principle.</p>

**Rode 2011** (Continued)

Selective reporting (reporting bias)	Low risk	All expected outcomes appear to have been reported.
Other bias	Low risk	Baseline characteristics were comparable for the groups but there were slightly more monochorionic gestations in the placebo group – but the difference was not statistically significant.  Multiple pregnancies - adjustments made for infant outcomes – present Relative Risks.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	“All participants and study personnel were blinded to treatment assignment for the duration of the trial, and the randomization code was not broken before all data had been collected, including the infant follow-up at 18 months of age.”
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Appears that outcome assessment was blinded – “Only the statistician and the independent Data Monitoring and Safety Committee had access to unblinded data during the study period”.

**Rouse 2007**

Methods	Method of randomisation: the "urn" method of randomisation. Allocation concealment: next of identical appearing treatment injections. Blinded outcome assessment: yes. Completeness of follow-up: 661 women randomised with outcome data available for 655 women.
Participants	661 women with a twin pregnancy; exclusion women with known fetal anomaly, spontaneous fetal death of a fetus after 12 weeks, presumed monoamniotic placenta, suspected twin-twin transfusion syndrome, marked ultrasonographic growth discordance, progesterone or heparin treatment during pregnancy, current or planned cervical cerclage, hypertension, insulin-dependent diabetes, and twin pregnancies that were the result of intentional fetal reduction.
Interventions	Weekly intramuscular injection of either 250 mg 17-hydroxyprogesterone caproate or placebo (castor oil) from 16 - 20 + 3 weeks until 34 completed weeks' gestation, or birth if earlier.
Outcomes	Primary outcome: composite of delivery or death prior to 35 weeks' gestation. Secondary outcomes: randomisation to delivery interval; composite adverse outcomes (retinopathy of prematurity, respiratory distress syndrome, sepsis, necrotising enterocolitis, bronchopulmonary dysplasia, grade III or IV intraventricular haemorrhage, periventricular leucomalacia), birthweight (less than 2500 g and less than 1500 g), 5-minute Apgar score < 7, patent ductus arteriosus, pneumonia, mechanical ventilation, seizures.  Preterm birth before 37 weeks' gestation; birthweight less than 2.5 kg; stillbirth; neonatal death; intraventricular haemorrhage; respiratory distress syndrome; bronchopulmonary dysplasia; sepsis; necrotising enterocolitis; retinopathy of prematurity; patent ductus arteriosus.
Notes	Trial conducted by the Maternal-Fetal Medicine Network, USA.

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	"The simple urn method of randomisation with stratification according to clinical center was used by the George Washington University Biostatistical Co-ordinating Center to create a randomization sequence for each center,..."

**Rouse 2007** (Continued)

Allocation concealment (selection bias)	Low risk	Adequate; identical appearing treatment packs.
Incomplete outcome data (attrition bias) All outcomes	Low risk	Outcome data available for 655 of 661 women (less than 1% loss to follow-up).
Selective reporting (reporting bias)	Low risk	All expected outcomes reported (delivery or fetal death before 35 weeks' gestation; other obstetric and neonatal outcomes) see table 2 and 3.
Other bias	Unclear risk	"Baseline demographic data were similar in the two study groups" (see table 1).  Multiple pregnancies - no adjustment in analysis apparent.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Women, caregivers and outcome assessors blinded.
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Women, caregivers and outcome assessors blinded.

**Rozenberg 2012**

Methods	Open-label randomised controlled trial.  Multicentre, 13 French university hospitals.
Participants	188 women randomised.  Inclusion criteria: women with singleton pregnancies admitted at 24 + 0 through 31 + 6 weeks of gestation with a cervical length < 25 mm for an episode of preterm labour that was then successfully arrested by tocolytic treatment. A course of betamethasone 12 mg, repeated after 24 hours, was given intramuscularly in all patients.  Exclusion criteria: cervical dilatation > 3cm, chorioamnionitis, fetal heart rate abnormalities, placenta previa, abruptio placentae, PROM, polyhydramnios, IUGR, pregnancy-related hypertension or pre-eclampsia, maternal or fetal condition requiring immediate delivery, anticonvulsive treatment or participation in any other trial.
Interventions	Experimental intervention: 500 mg of intramuscular 17 alpha-hydroxyprogesterone caproate (17 P) started after tocolysis ended and repeated twice weekly until 36 weeks or until preterm delivery.  Control/Comparison intervention: no treatment with 17P. Additional management in the 2 arms was left to the discretion of the attending physician, except that progesterone was not allowed in the control group.
Outcomes	Time from randomisation to delivery, preterm delivery before 37, 34 and 32 weeks, readmissions for preterm labour, NICU, birthweight, respiratory distress, bronchopulmonary dysplasia, necrotising enterocolitis, periventricular leucomalacia, perinatal death, severe maternal or neonatal adverse effect.
Notes	

**Rozenberg 2012** (Continued)

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Centralised, computer-generated randomisation process in a 1:1 ratio.
Allocation concealment (selection bias)	Unclear risk	Not described.
Incomplete outcome data (attrition bias) All outcomes	Low risk	A total of 188 women were randomised.  Outcome data available for 184 women.  States "assessed according to the intention-to-treat principle".
Selective reporting (reporting bias)	Low risk	All expected outcome results reported.
Other bias	Unclear risk	A subsequent letter to the journal questioned the use of the study medication unless it had been tested for purity and many samples of the medication did not meet FDA specifications. The letter stated that this casts doubt on the findings of any study using 17Pc. The authors confirmed that the study medication was not of questionable quality.  Study groups appeared similar at baseline although 12% of the intervention group and 24% of controls had had a previous preterm delivery.
Blinding of participants and personnel (performance bias) All outcomes	High risk	No blinding - trial is described as "open label".
Blinding of outcome assessment (detection bias) All outcomes	High risk	Not mentioned. High risk of bias (randomisation to the control group may have affected subsequent treatment and outcome assessment).

**Saghafi 2011a**

Methods	Described as an interventional study.  Obstetrics Clinic of Ghaem Hospital, Mashad University of Medical Sciences, Iran.
Participants	100 women randomised: 50 allocated to progesterone and 50 allocated to placebo.  Inclusion criteria: pregnant women with a previous history of preterm delivery who had no contraindication for continuing pregnancy.

**Saghafi 2011a** (Continued)

Exclusion criteria: women who had entered the active phase of delivery, cases of preterm PROM, pre-eclampsia, vaginal bleeding, maternal-fetal diseases for which continuation of the pregnancy was dangerous, symptoms of distress, and fetal anomalies.

Interventions	<p>Experimental intervention: 250 mg of intramuscular 17 alpha-hydroxyprogesterone caproate (17 P) weekly from 16 weeks' gestation up to a maximum of 37 weeks' gestation.</p> <p>Control/Comparison intervention: routine perinatal care.</p>
Outcomes	<p>Preterm delivery (&lt; 37 weeks).</p> <p>Apgar score at 1 and 5 minutes (mean values given).</p> <p>Newborn weight (g) mean values.</p> <p>Vaginal delivery (n).</p> <p>Low birthweight neonates (%) – didn't specify what low birthweight was.</p>

Notes

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Not described - just says "They were randomly divided into two groups...".
Allocation concealment (selection bias)	Unclear risk	Not described.
Incomplete outcome data (attrition bias) All outcomes	Low risk	Appears to be no loss. Outcome data available for all 100 women, 50 randomised to each group.
Selective reporting (reporting bias)	Unclear risk	Data limited – only reported as an abstract.
Other bias	Low risk	States that the 2 groups were similar for age, gravidity, abortions, previous preterm births - see table 1.
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Not described.
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not described.

**Senat 2012**

Methods	Open-label multicentre, randomised controlled trial in France – 13 French university hospitals.
Participants	165 women randomised and 161 followed up – it was not clear how many were randomised to each group.

**Senat 2012** (Continued)

Inclusion criteria: asymptomatic women with twin pregnancy and cervical length < 25 mm between 20 and 32 weeks of gestation.

Exclusion criteria: not reported in the abstract.

**Interventions**

Experimental intervention: 500 mg intramuscular 17 alpha-hydroxyprogesterone caproate (17P) – twice weekly until 36 weeks or until preterm delivery.

Control/Comparison intervention: no 17P.

Additional management in the 2 arms was left to the discretion of the attending physician, except that progesterone was not allowed in the control group.

**Outcomes**

Median time to delivery; delivery before 32 and 34 weeks' gestation.

**Notes**

Not able to report any outcome data because the number randomised to each group is not stated.

**Risk of bias**

<b>Bias</b>	<b>Authors' judgement</b>	<b>Support for judgement</b>
Random sequence generation (selection bias)	Low risk	Randomly assigned by computer-generated randomisation process in a 1:1 ratio.
Allocation concealment (selection bias)	Low risk	States – central randomisation. "A centralised, computer generated randomised process in a 1:1 ratio."
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	Unclear – limited data reported as only an abstract.
Selective reporting (reporting bias)	Unclear risk	Unclear – limited data reported as only an abstract.
Other bias	Unclear risk	Unclear – limited data reported as only an abstract.
Blinding of participants and personnel (performance bias) All outcomes	High risk	Described as an "open label trial".
Blinding of outcome assessment (detection bias) All outcomes	High risk	Described as an "open label trial".

**Serra 2013**

**Methods**

3-arm RCT in 5 centres in Spain, individual randomisation.

**Participants**

294 women attending 1 of 5 university hospital centres in Spain between December 2005 and January 2008.

Inclusion criteria: women were recruited at 11-13 weeks' gestation. If they had previously been treated with vaginal progesterone it was stopped. Women were 18 years or more, dichorionic, diamniotic twin pregnancy.

**Serra 2013** (Continued)

Exclusion criteria: singleton pregnancy, mono-chorionic twin pregnancies, triplets or higher multiple pregnancies, elective cervical cerclage before 14 weeks' gestation, history of hepatic problems, pregnancy cholestasis, abnormal liver or kidney function, allergy to peanuts or study medication, recurrent vaginal bleeding or infection, fetal anomalies, alcohol or illicit drug use and smoking more than 10 cigarettes per day.

Interventions	Intervention:  1. 200 mg vaginal progesterone self-inserted daily at bedtime. (98 women).  2. 400 mg vaginal progesterone self-inserted daily at bedtime (98 women).  3. (control) placebo vaginal pessaries self-inserted daily at bedtime (98 women).  All women were provided with specially manufactured identical looking pessaries, 2 to be administered each evening.  Total number randomised: n = 294.	
Outcomes	Preterm birth rate < 37 weeks of gestation; early preterm birth rate < 34, 32, 28 weeks of gestation; need for tocolytic treatment; steroid treatment; rate of preterm premature rupture of membranes < 37 weeks of gestation; cervical length measurements at 20, 24, 28 weeks of gestation; perinatal mortality and morbidity; caesarean section. Local tolerance to the treatment; number of serious systemic adverse effects.  Perinatal outcomes: short-term neonatal morbidity (respiratory distress syndrome; pneumonia; early onset sepsis; seizures; graded III-IV intraventricular haemorrhage; stage II-II necrotising enterocolitis; and/or patent duct arteriosus). Long-term neonatal morbidity included: broncho-pulmonary dysplasia; periventricular leucomalacia; and/or severe retinopathy of prematurity.  Birthweight < 2500 g; 5 minute Apgar score; major congenital malformation; admission to NICU; mechanical ventilation; neonatal death.	
Notes		
<b>Risk of bias</b>		
<b>Bias</b>	<b>Authors' judgement</b>	<b>Support for judgement</b>
Random sequence generation (selection bias)	Low risk	"Randomisation was performed by computer (SPSS Random Number Generator, using a randomisation sequence 1:1:1 ratio (blocks of nine, with no stratification)."
Allocation concealment (selection bias)	Low risk	Central allocation "An external monitoring centre provided a randomisation code number for each pregnant woman" "The medication was given at each visit by the hospital pharmacy department."
Incomplete outcome data (attrition bias) All outcomes	Low risk	It was stated that an ITT analysis was carried out. There was very little loss to follow-up.  294 randomised at 20 weeks.  290 analysed – analysed as ITT.  Placebo group – n = 98, n = 10 discontinued study, n = 2 lost to follow-up, 96 analysed  200 mg progesterone group = n = 98, n = 11 discontinued study, n = 1 lost to follow-up, 97 analysed.  400 mg progesterone group = n = 98, n = 10 discontinued study, n = 1 lost to follow-up, 97 analysed.

**Serra 2013** (Continued)

Selective reporting (reporting bias)	Unclear risk	Most expected outcomes reported upon. However – individual outcome results for short-term and long-term neonatal morbidity were not reported, e.g. respiratory distress syndrome, periventricular leucomalacia.
Other bias	Unclear risk	Baseline characteristics similar. Management may have differed in the 5 participating centres although this was not clear. Groups appeared similar at baseline.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Women and staff were blinded. Medication packs were coded and contained identical appearing pessaries.
Blinding of outcome assessment (detection bias) All outcomes	Low risk	It was reported that all study personnel were blind to treatment allocation for the duration of the project.

**Sharami 2010**

Methods	Described as placebo-controlled double-blind RCT. Alzghara Hospital, Iran. Recruitment between 2007 and 2009.	
Participants	<p>Inclusion criteria: 173 randomised. Women with singleton pregnancies, gestational age 28-36 weeks admitted with threatened preterm labour successfully treated with tocolysis with intact membranes and less than 2cm cervical dilatation.</p> <p>Exclusion criteria: patients with intrauterine infection, vaginal bleeding, pre-eclampsia, urinary tract infection, intrauterine growth retardation, hypertension and heart disease, dilatation <math>\geq</math> 2 cm, fetal distress and fetal abnormalities.</p>	
Interventions	<p>Intervention: n = 86 women. 200 mg vaginal progesterone daily until 36 weeks' gestation.</p> <p>Control/comparison intervention: n = 87 women. Placebo vaginal suppositories until 36 weeks' gestation.</p> <p>All patients (in both groups) received 12 mg betamethasone and antibiotic prophylaxis and advised to restrict physical activity.</p>	
Outcomes	<p>Primary:</p> <p>Time until delivery (latency time)</p> <p>PTB before 34 and 37 weeks of gestation</p> <p>Secondary:</p> <p>Selected maternal and neonatal outcomes including nausea, headache, pre-eclampsia, PROM, chorioamnionitis, post-partum haemorrhage for maternal complications and birth weight, Apgar score, admission to the NICU, fetal death, neonatal death, RDS, sepsis, and intraventricular haemorrhage (IVH).</p>	
Notes		
<b>Risk of bias</b>		
<b>Bias</b>	<b>Authors' judgement</b>	<b>Support for judgement</b>

**Sharami 2010** (Continued)

Random sequence generation (selection bias)	Unclear risk	Just states, "Random block allocation method" – no other details.
Allocation concealment (selection bias)	Unclear risk	No details reported.
Incomplete outcome data (attrition bias) All outcomes	Low risk	270 eligible, 97 women delivered within 48 hours, a total of 173 randomised.  Placebo group – n = 87, n = 4 lost to follow-up, 83 completed follow-up – 83 included in analysis.  Progesterone group = n = 86, n = 6 lost to follow-up, 80 completed follow-up – 80 included in analysis.
Selective reporting (reporting bias)	Unclear risk	Not clear. Several outcomes stated as secondary outcomes in the methods were not reported (this may have been because there were no cases but this was not stated, e.g. fetal death, intraventricular haemorrhage).
Other bias	Low risk	Baseline characteristics similar.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Both patients and physician were blinded to the type of suppositories.
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Described as double-blind. Not clear if outcome assessment was blind.

CNS: central nervous system

CPAP: continuous positive airways pressure

ITT: intention-to-treat

ICSI: intracytoplasmic sperm injection

IUGR: intrauterine growth restriction

IVF: in vitro fertilisation

LSCS: lower segment Caesarian section

LMP: last menstrual period

NICU: neonatal intensive care unit

PROM: premature rupture of membranes

PPROM: preterm premature rupture of membranes

PTB: preterm birth

RDS: respiratory distress syndrome

SD: standard deviation

**Characteristics of excluded studies** [ordered by study ID]

Study	Reason for exclusion
<a href="#">Abbott 2012</a>	RCT embedded in a longitudinal study, but comparison of progesterone versus cerclage, so not relevant to this review.
<a href="#">Arıkan 2011</a>	Acute treatment – being used as a tocolytic.
<a href="#">Berghella 2010</a>	Women were randomised to cerclage versus no cerclage – not randomised to 17P use or not – stratified at randomisation to intent to use or not use 17P.
<a href="#">Breart 1979</a>	Progesterone administration for prevention of miscarriage.

Study	Reason for exclusion
<a href="#">Brenner 1962</a>	Progesterone administration for prevention of miscarriage.
<a href="#">Chandiramani 2012</a>	Not clear that this is an RCT and also compares progesterone with cerclage, so not relevant to this review.
<a href="#">Corrado 2002</a>	Progesterone administered after amniocentesis for the prevention of miscarriage.
<a href="#">Hobel 1986</a>	Compares an oral progesterone agent with placebo but the only outcome reported is the rate of preterm birth as a percentage (not able to determine n = in either progesterone or placebo group). Other results reported as experimental group versus control (this allocation is not randomised but based on risk assessment at first and second antenatal visit).
<a href="#">Ionescu 2012</a>	Progesterone versus cerclage – so not relevant to this review.
<a href="#">Keeler 2009</a>	Comparison with McDonald cerclage, not placebo – topic of another review.
<a href="#">Le Vine 1964</a>	Quasi-randomised trial.
<a href="#">Rust 2006</a>	Progesterone versus cerclage – so not relevant to this review.
<a href="#">Suvonnakote 1986</a>	Quasi-randomised trial - women were 'divided' into 2 groups (trial group and control group).
<a href="#">Turner 1966</a>	Progesterone administration for prevention of miscarriage.
<a href="#">Walch 2005</a>	Progesterone administration for prevention of miscarriage.
<a href="#">Yemini 1985</a>	Quasi-randomised trial.

RCT: randomised controlled trial

### Characteristics of ongoing studies *[ordered by study ID]*

#### [Coomarasamy 2012](#)

Trial name or title	Progesterone in recurrent miscarriages (PROMISE) study.
Methods	
Participants	<ol style="list-style-type: none"> <li>1. Women with unexplained recurrent miscarriages (3 or more consecutive first trimester miscarriages).</li> <li>2. Age 18-39 years at randomisation (likelihood of miscarriages due to chromosomal aberrations is higher in older women; such miscarriages are unlikely to be prevented by progesterone therapy).</li> <li>3. Spontaneous conception (as confirmed by urinary pregnancy tests).</li> <li>4. Willing and able to give informed consent.</li> </ol>
Interventions	<p>Intervention group: progesterone pessaries (400 mg twice daily) started soon as possible after a positive pregnancy test (and no later than 6 weeks' gestation) and continued to 12 weeks of gestation.</p> <p>Control group: placebo.</p> <p>Total duration of follow-up per participant: 42 weeks.</p>
Outcomes	<p>Primary outcome: live births beyond 24 weeks.</p> <p>Secondary outcomes:</p>

### Coomarasamy 2012 *(Continued)*

1. Gestation at delivery.
2. Clinical pregnancy at 6-8 weeks.
3. On-going pregnancy at 12 weeks (range 11-13 weeks).
4. Miscarriage rate.
5. Survival at 28 days of neonatal life.
6. Congenital abnormalities with specific examination for genital anomalies.
7. Adverse events.

Starting date	01/05/2009, anticipated end date 0105/2012.
Contact information	Dr Arri Coomarasamy: a.coomarasamy@bham.ac.uk
Notes	

### Creasy 2008

Trial name or title	The effect of vaginal progesterone administration in the prevention of preterm birth in women with a short cervix. NCT00615550.
Methods	
Participants	Women with a singleton gestation and a short cervical length by transvaginal ultrasound defined as 10-20 mm.
Interventions	Progesterone 8% vaginal gel, 1.125 g once daily, beginning at 19 0/7 to 23 6/7 weeks' gestation through 36 6/7 weeks' gestation.  Placebo vaginal gel, 1.125 g once daily, beginning at 19 0/7 to 23 6/7 weeks' gestation through 36 6/7 weeks' gestation.
Outcomes	Reduction in the frequency of preterm birth (less than or equal to 32 6/7 weeks' gestation).
Starting date	March 2008.
Contact information	Joseph R Parella: <a href="mailto:jparella@columbialabs.com">jparella@columbialabs.com</a>
Notes	

### Crowther 2007

Trial name or title	Progesterone for the prevention of neonatal respiratory distress syndrome (The PROGRESS Study). ISRCTN20269066.
Methods	
Participants	Women with a history of previous spontaneous preterm birth.
Interventions	Daily vaginal progesterone vs placebo.
Outcomes	Neonatal lung disease.
Starting date	October 2005.

**Norman 2012** *(Continued)*

	ISRCTN14568373.
Methods	Double-blind randomised placebo controlled trial.
Participants	Women with singleton pregnancy and at high risk of preterm labour.
Interventions	Prophylactice vaginal natural progesterone, 200 mg daily from 22-34 weeks' gestation vs placebo.
Outcomes	Incidence of preterm delivery (before 34 weeks); neonatal outcome (composite of death and major morbidity); childhood cognitive and neurosensory outcomes at 2 years of age.
Starting date	Recruitment began in 2009 and is scheduled to close in Spring 2013.
Contact information	Jane E Norman.
Notes	

**Perlitz 2007**

Trial name or title	Prevention of recurrent preterm delivery by a natural progesterone agent. NCT00329316.
Methods	
Participants	Women with preterm labour in a prior pregnancy.
Interventions	Daily vaginal progesterone gel vs placebo.
Outcomes	Not specified.
Starting date	Not yet recruiting.
Contact information	Yuri Perlitz: yperlitz@poria.health.gov.il
Notes	

**Starkey 2008**

Trial name or title	Comparing intramuscular versus vaginal progesterone for prevention of preterm birth. NCT00579553.
Methods	
Participants	Women with singleton pregnancies and history of prior spontaneous preterm birth.
Interventions	Weekly intramuscular injection of 17 alpha hydroxylprogesterone caproate (250 mg) or daily vaginal progesterone (100 mg).
Outcomes	Maternal, fetal and neonatal outcomes.
Starting date	October 2006.

**Starkey 2008** (Continued)

Notes

**Swaby 2007**

Trial name or title Pilot randomised controlled trial of vaginal progesterone to prevent preterm birth in multiple pregnancy.

Methods

Participants Women with a multiple pregnancy.

Interventions Vaginal progesterone (90 mg) or placebo gel.

Outcomes Duration of pregnancy.

Starting date

Contact information C Swaby. University of Calgary, 1403-29 Street, Calgary, Canada.

Notes

**van Os 2011**

Trial name or title Preventing preterm birth with progesterone: costs and effects of screening low risk women with a singleton pregnancy for short cervical length, the Triple P study.

Netherlands Trial Register (NTR): NTR207.

Methods

Cohort study with a randomised placebo-controlled trial embedded.

Multicentre, Dutch Obstetric Consortium.

 Participants Inclusion criteria: women with low risk singleton pregnancies at 18-22 weeks' gestation with a short cervix  $\leq$  30 mm.

Interventions Vaginal progesterone 200 mg-capsules of micronised progesterone - vs placebo, taken between 22 and 34 weeks.

Outcomes Primary outcome: composite poor neonatal outcome (death or severe morbidity): severe respiratory distress syndrome; bronchopulmonary dysplasia; periventricular leucomalacia &gt; grade 1; intracerebral haemorrhage &gt; grade II; necrotising enterocolitis &gt; stage 1; proven sepsis and death before discharge from the nursery.

Secondary outcomes: time to delivery; preterm birth rate before 32, 34 and 37 weeks; days of admission in neonatal intensive care unit; maternal morbidity; maternal admission days for preterm labour; costs; growth, physical condition (close examination of genital tract), neurodevelopmental outcome of child at 24 month age; cost-effectiveness of screening for short cervical length.

Starting date October 2011 - not clear from paper.

Notes

**Wood 2007**

Trial name or title Vaginal progesterone versus placebo in multiple pregnancy. NCT00343265.

Methods

Participants Women with a multiple pregnancy.

Interventions Daily vaginal progesterone gel vs placebo.

Outcomes Primary: gestational age.

Starting date June 2006.

Contact information Stephen Wood: stephen.wood@calgaryhealthregion.ca

Notes

IM: intramuscular  
 vs: versus

**DATA AND ANALYSES**

**APPENDICES**

**Appendix 1. Search methods used for previous version of this review**

We searched the Cochrane Pregnancy and Childbirth Group’s Trials Register by contacting the Trials Search Co-ordinator (December 2008).

The Cochrane Pregnancy and Childbirth Group’s Trials Register is maintained by the Trials Search Co-ordinator and contains trials identified from:

1. quarterly searches of the Cochrane Central Register of Controlled Trials (CENTRAL);
2. weekly searches of MEDLINE;
3. weekly searches of EMBASE;
4. handsearches of 30 journals and the proceedings of major conferences;
5. weekly current awareness alerts for a further 44 journals plus monthly BioMed Central email alerts.

Details of the search strategies for CENTRAL, MEDLINE and EMBASE, the list of handsearched journals and conference proceedings, and the list of journals reviewed via the current awareness service can be found in the ‘Specialized Register’ section within the editorial information about the [Cochrane Pregnancy and Childbirth Group](#).

Trials identified through the searching activities described above are each assigned to a review topic (or topics). The Trials Search Co-ordinator searches the register for each review using the topic list rather than keywords.

In addition, we searched CENTRAL (*The Cochrane Library* 2008, Issue 1). See below for search terms.

We did not apply any language restrictions.

**Searching other resources**

We also manually cross referenced key publications.

We did not apply any language restrictions.

We searched the International Clinical Trials Register (using the terms pregnancy, progesterone and ante/prenatal) to identify ongoing registered clinical trials.

### Search terms for CENTRAL

Search terms included free text terms pregnancy, preterm birth, progesterone, progestogen, intramuscular, vaginal, oral, perinatal morbidity, perinatal mortality, and randomis(z)ed controlled trial. Please contact review author for exact strategy.

### Appendix 2. Methods for the previous version of this review

We used the standard methods of The Cochrane Collaboration (Higgins 2008). Review authors independently assessed trials for inclusion in the review and extracted the data. Any differences were resolved by discussion with all co-authors.

#### Assessment of risk of bias in included studies

The methodology used to assess risk of bias of studies included in the previous version of this review is given in [Appendix 2](#).

For this update, the following methods were used.

Two review authors independently assessed risk of bias for each study using the criteria outlined in the *Cochrane Handbook for Systematic Reviews of Interventions* (Higgins 2008). Any disagreement was resolved by discussion or by involving a third assessor.

#### (1) Sequence generation (checking for possible selection bias)

We describe for each included study the method used to generate the allocation sequence in sufficient detail to allow an assessment of whether it should produce comparable groups.

We assessed the method as:

- adequate (any truly random process, e.g., random number table; computer random number generator);
- inadequate (any non random process, e.g., odd or even date of birth; hospital or clinic record number);
- unclear.

#### (2) Allocation concealment (checking for possible selection bias)

We describe for each included study the method used to conceal the allocation sequence in sufficient detail and determine whether intervention allocation could have been foreseen in advance of, or during recruitment, or changed after assignment.

We assessed the methods as:

- adequate (e.g., telephone or central randomisation; consecutively numbered sealed opaque envelopes);
- inadequate (open random allocation; unsealed or non-opaque envelopes, alternation; date of birth);
- unclear.

#### (3) Blinding (checking for possible performance bias)

We describe for each included study the methods used, if any, to blind study participants and personnel from knowledge of which intervention a participant received. Studies will be judged at low risk of bias if they were blinded, or if we judge that the lack of blinding could not have affected the results. Blinding will be assessed separately for different outcomes or classes of outcomes.

We assessed the methods as:

- adequate, inadequate or unclear for participants;
- adequate, inadequate or unclear for personnel;
- adequate, inadequate or unclear for outcome assessors.

#### (4) Incomplete outcome data (checking for possible attrition bias through withdrawals, dropouts, protocol deviations)

We describe for each included study, and for each outcome or class of outcomes, the completeness of data including attrition and exclusions from the analysis. We state whether attrition and exclusions were reported, the numbers included in the analysis at each stage (compared with the total randomised participants), reasons for attrition or exclusion where reported, and whether missing data were balanced across groups or were related to outcomes. Where sufficient information was reported, or was supplied by the trial authors, we re-included missing data in the analyses which we undertook. We assessed methods as:

- adequate;
- inadequate;
- unclear;

where 'adequate' is less than 20% losses to follow-up.

### (5) Selective reporting bias

We describe for each included study how we investigated the possibility of selective outcome reporting bias and what we found.

We assessed the methods as:

- adequate (where it is clear that all of the study's pre-specified outcomes and all expected outcomes of interest to the review have been reported);
- inadequate (where not all the study's pre-specified outcomes have been reported; one or more reported primary outcomes were not pre-specified; outcomes of interest are reported incompletely and so cannot be used; study fails to include results of a key outcome that would have been expected to have been reported);
- unclear.

### (6) Other sources of bias

We describe for each included study any important concerns we have about other possible sources of bias.

We assessed whether each study was free of other problems that could put it at risk of bias:

- yes;
- no;
- unclear.

### (7) Overall risk of bias

We made explicit judgements about whether studies are at high risk of bias, according to the criteria given in the *Cochrane Handbook* (Higgins 2008). With reference to (1) to (6) above, we assessed the likely magnitude and direction of the bias and whether we considered it was likely to impact on the findings. We explored the impact of the level of bias through undertaking sensitivity analyses.

### Data management and analysis

We conducted data management and analysis using RevMan software (RevMan 2008). V Flenady, R Cincotta and J Dodd independently extracted data. Results are reported as mean differences for continuous variables, and risk ratios for categorical outcomes, both with 95% confidence intervals.

We conducted the meta-analysis using the fixed-effect model, and assessed heterogeneity by visual inspection of the outcomes tables and by using two statistics (H and I<sup>2</sup> test) of heterogeneity (Higgins 2002). Where we discovered statistical heterogeneity, this was explored.

Results are presented by reason women were considered to be at risk of preterm birth, including:

- past history of spontaneous preterm birth (including preterm premature rupture of membranes);
- multiple pregnancy;
- ultrasound identified short cervical length;
- fetal fibronectin testing;
- presentation with symptoms or signs of threatened preterm labour;
- other reason for risk of preterm birth.

Planned subgroup analyses included an assessment of the effect of: (1) time of treatment commencing (before 20 weeks' gestation versus after 20 weeks' gestation); (2) route of administration (intramuscular, intravaginal, oral, intravenous); and (3) different dosage regimens (divided arbitrarily into a cumulative dose of less than 500 mg per week and a dose of greater than or equal to 500 mg per week). To evaluate the effect of subgroup comparisons, we considered confidence intervals (where non-overlap was taken to indicate a statistically significant difference).

### WHAT'S NEW

Date	Event	Description
27 July 2015	Amended	Corrected spelling of included study <a href="#">Fonseca 2007</a> (was previously listed as Fonesca 2007).

Date	Event	Description
		Text has been added to <a href="#">Published notes</a> about this review being split into two reviews following two new protocols.

## HISTORY

Protocol first published: Issue 4, 2004

Review first published: Issue 1, 2006

Date	Event	Description
13 August 2013	Amended	Robert Cincotta added to the byline. Contribution to this update added.
5 August 2013	Amended	Contact details amended for Caroline Crowther.
12 June 2013	New citation required and conclusions have changed	<p>This updated review is now comprised of 36 included studies (involving 8523 women and 12,515 infants). There are now 11 ongoing studies. The results and conclusions have changed:</p> <p>Progesterone versus placebo for women with a history of preterm birth: now significant findings for perinatal mortality; significant findings for additional infant and maternal secondary outcomes.</p> <p>Progesterone versus placebo for women with a short cervix: significant findings now identified for secondary infant outcome (preterm birth less than 28 weeks' gestation) and secondary maternal outcome (adverse drug reaction (urticaria); now no significant findings for neonatal sepsis.</p> <p>Progesterone versus placebo for women with a multiple pregnancy: now no significant findings for any of the reported outcomes.</p> <p>Progesterone versus no treatment/placebo for women following presentation with threatened preterm labour: now no significant findings for two secondary infant outcomes (preterm birth less than 37 weeks' gestation; respiratory distress syndrome (RDS)).</p> <p>Progesterone versus placebo for women with 'other' risk factors for preterm birth: now significant findings for one secondary infant outcome (infant birthweight less than 2500 g).</p>
14 January 2013	New search has been performed	<p>Search updated.</p> <p>Data from 25 new trials incorporated into this update.</p>
27 January 2012	Amended	Fifty-two reports for 44 trials added to Studies awaiting classification.
31 December 2008	New search has been performed	<p>Search updated. A search in October 2007 identified 17 new trials. We included five (<a href="#">Borna 2008</a>; <a href="#">Facchinetti 2007</a>; <a href="#">Fonseca 2007</a>; <a href="#">O'Brien 2007</a>; <a href="#">Rouse 2007</a>); added a follow-up report to <a href="#">Meis 2003</a>; and excluded one (<a href="#">Walch 2005</a>). Ten trials are ongoing (<a href="#">Bruinse 2007</a>; <a href="#">Maurel 2007</a>; <a href="#">Grobman 2007</a>; <a href="#">Martinez 2007</a>; <a href="#">Nassar 2007</a>; <a href="#">Perlitz 2007</a>; <a href="#">Rode 2007</a>; <a href="#">Rozenberg 2007</a>; <a href="#">Serra 2007</a>; <a href="#">Wood 2007</a>).</p>

Date	Event	Description
		<p>A further updated search in December 2008 identified one more report of <a href="#">Borna 2008</a>; five more reports of <a href="#">O'Brien 2007</a>; six more reports of <a href="#">Rouse 2007</a>; one more report of <a href="#">Crowther 2007</a>; one more report of <a href="#">Bruinse 2007</a>; three ongoing studies (<a href="#">Creasy 2008</a>; <a href="#">Starkey 2008</a>; <a href="#">Swaby 2007</a>); and one study which is awaiting classification (<a href="#">Moghtadaei 2008a</a>).</p> <p>The review's conclusions have not changed.</p>
5 November 2008	Amended	Converted to new review format.
31 March 2005	New search has been performed	Search updated and new studies found and included or excluded.

## CONTRIBUTIONS OF AUTHORS

For the update in 2013, J Dodd and L Jones assessed studies, extracted data and entered it into RevMan. L Jones wrote the first version of the results. J Dodd revised the review, discussion and conclusions. V Flenady, CA Crowther and R Cincotta commented on all drafts of the update (2013).

## DECLARATIONS OF INTEREST

J Dodd, V Flenady and C Crowther are investigators in a randomised trial assessing the use of progesterone for prevention of respiratory distress syndrome (The PROGRESS Trial).

## DIFFERENCES BETWEEN PROTOCOL AND REVIEW

In view of the increase in the number of trials published, along with the huge variation in the patient populations recruited, we have decided to categorise the studies by the reason women were considered to be at increased risk of preterm birth. We have also included longer-term childhood health outcomes, in recognition of the need for ongoing follow-up of children exposed antenatally to progesterone (Update 2008), and maternal quality of life (Update 2013).

## NOTES

This review examines prenatal administration of progesterone for preventing preterm birth in women considered to be at risk of preterm birth. Women considered in this review includes women considered at high risk because of multiple pregnancy as well as women with singleton pregnancies considered at high risk for various clinical reasons (history of preterm birth, short cervix, threatened preterm labour and other risk factors). This review included 36 trials with several trials recruiting only women with multiple pregnancies. The results of this review may be easier to interpret and more clinically relevant if the results for women with multiple and singleton pregnancy are assessed and reported separately.

Consequently, this review will no longer be updated in it's current form but will be split into two separate reviews:

- Prenatal administration of progesterone for preventing preterm birth in women with a multiple pregnancy
- Prenatal administration of progesterone for preventing preterm birth in women with a singleton pregnancy

---

Each of these reviews will be prepared following publication of a new protocol.

## INDEX TERMS

### Medical Subject Headings (MeSH)

17-alpha-Hydroxyprogesterone [administration & dosage] [adverse effects]; Pregnancy, High-Risk; Premature Birth [\*prevention & control]; Prenatal Care [methods]; Progesterone [\*administration & dosage] [adverse effects]; Randomized Controlled Trials as Topic

### MeSH check words

Female; Humans; Pregnancy
