ABSTRACT

Background

Acute urinary retention is a urological emergency in men and requires urgent catheterisation. Any intervention which aims at improving urinary symptoms following an acute urinary retention episode could be potentially beneficial. Alpha blockers relax prostatic smooth muscle cells thereby decreasing the resistance to urinary flow and by doing so could improve urinary symptoms.

Objectives

To assess the effectiveness of alpha blockers on successful resumption of micturition following removal of a urethral urinary catheter after an episode of acute urinary retention in men. In the absence of internationally agreed outcome measures for the success of a trial without catheter, success was defined as the return to satisfactory voiding without need for re-catheterisation within 24 hours.

Search methods

We searched the Cochrane Incontinence Group Specialised Trials Register, which contains trials identified from the Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE, MEDLINE in process, and handsearching of journals and conference proceedings (searched 9 October 2013), CENTRAL (2013, Issue 5) (searched 5 June 2013), MEDLINE 1946 to May Week 4 2013, MEDLINE in Process (covering to 3 June 2013), EMBASE Classic and EMBASE 1947 to 2013 Week 22 (all searched 4 June 2013) and the reference lists of relevant articles. No language or other restrictions were imposed on the searches.

Selection criteria

Only randomised and quasi-randomised clinical trials of alpha blockers for trial without a urethral catheter following an episode of acute urinary retention in men were included.

Data collection and analysis

Two review authors independently examined all the citations and abstracts derived from the search strategy. Any disagreement about trial selection and inclusion was resolved by discussion. A third independent judgement was sought where disagreement persisted. Two review authors extracted independently, cross-checked and processed the data as described in the *Cochrane Handbook for Systematic Reviews of Intervention*. Quality of evidence of the critical outcomes was assessed by adopting the GRADE approach.

Main results

Nine randomised clinical trials were included in this review. Eight trials compared alpha blockers versus placebo (five trials tested alfuzosin and two trials tested tamsulosin, one trial tested both alfuzosin and tamsulosin, one trial tested silodosin) and one trial compared an alpha blocker (doxazosin) versus no treatment. Trial without catheter was performed after treatment with the drug for one to three days in seven trials and for eight and 32 days in two other trials respectively. There was moderate quality evidence to suggest that the rate of successful trial without catheter favoured alpha blockers over placebo (366/608, 60.2%, of men using an alpha blocker were able to void spontaneously after catheter removal compared with 185/486, 38.1%, using placebo, risk ratio (RR) 1.55, 95% confidence interval (CI) 1.36 to 1.76). The incidence of recurrent acute urinary retention was lower in groups treated with an alpha blocker (RR 0.69, 95% CI 0.60 to 0.79). This evidence was of moderate quality and was statistically significant for alfuzosin, tamsulosin and silodosin, though not for doxazosin. Of the trials mentioning adverse effects (for example, postural hypotension, dizziness), there was not enough information to detect statistically significant differences between the groups (RR 1.19, 95% CI 0.75 to 1.89) and the evidence was of low quality. Overall, adverse effect rates were low for both placebo and alpha blockers and, for example, vasodilatation-related adverse effects did not often result in discontinuation. However, the data in this review are limited due to the large amount of unpublished data that was not available to us.

Authors' conclusions

There was some evidence to suggest that alpha blockers increase the success rates of trial without catheter, and the incidence of adverse effects was low. There was some evidence of a decreased incidence of acute urinary retention. The need for further surgery, cost effectiveness and recommended duration of alpha blocker treatment after successful trial without catheter remain unknown as these were not reported by any trial. There is a lack of internationally agreed outcome measures for what constitutes successful trial without catheter. This makes meta-analysis difficult. Large, well-designed controlled trials, which use the recommendations set out in the CONSORT statement, and include clinically important outcome measures, are required.

PLAIN LANGUAGE SUMMARY

Alpha blocker treatment for men to increase chances to have urinary catheter successfully removed

Background on the condition

Acute urinary retention in men is a medical emergency characterised by the sudden and often painful inability to pass urine. There are many known causes including prostate obstruction (because of enlargement of the prostate or cancer), urethral strictures (a narrowing of the urethra due to scar tissue), urine infection, constipation and neurological conditions. A narrow drainage tube (urinary catheter) is temporarily inserted into the bladder through the penis to allow drainage of urine. Once the catheter is removed, some men fail to pass urine again and need to be re-catheterised. In these men, continued use of catheters or prostate surgery are the standard treatment options. Catheters are associated with risks such as infection and can harm quality of life. Measures for increasing the rate of successful catheter removal, that is, enabling patients to urinate spontaneously again, are therefore potentially beneficial. Alpha blockers (for example tamsulosin, alfuzosin) are a group of drugs known to have positive effects on urinary symptoms such as poor urinary flow. It is believed that their relaxing effect on the prostate may also increase the chance to void again after catheter removal. This review evaluated the evidence available to support this practice.

The main findings of the review

In nine clinical trials men were either given a dummy tablet (placebo, inactive drug), an alpha blocker for one to three days (in one study up to a maximum of eight days and in another for 32 days) or no treatment before the catheter was removed. In ideal circumstances, neither patients nor doctors knew which type of tablet was given, to prevent the bias in reporting the results. The results suggested that alpha blocker treatment increased the chances of successful catheter removal and return to urination although the overall scientific evidence available to support this was limited. Four different alpha blockers were tested (alfuzosin, tamsulosin, doxazosin and silodosin). Their results were similar except for doxazosin which did not seem to make a significant difference.

Adverse effects

Side effects caused by alpha blockers were few and comparable to placebo or no treatment, though this evidence was limited. They included retrograde ejaculation, dizziness, low blood pressure, fainting, sleepiness, feeling unwell and headache.

Conclusions

There was some evidence to say that alpha blockers also reduce the risk of suffering another (recurrent) episode of urinary retention after successful catheter removal, though it remains unclear whether they reduce the need for future surgery on the prostate. It is therefore unclear whether, or for how long, alpha blocker treatment should be continued after successful catheter removal and whether the costs of alpha blocker treatment in such situations are justified. Further research is needed to answer these questions.

SUMMARY OF FINDINGS

Summary of findings for the main comparison. Alpha blocker versus placebo or control for acute urinary retention in adult men

Alpha blocker versus placebo or control for acute urinary retention in adult men

Patient or population: acute urinary retention in adult men

Intervention: Alpha blocker versus placebo or control

Outcomes	Illustrative comparative risks* (95% CI)		Relative effect (95% CI)	No of Participants (studies)	Quality of the evidence (GRADE)	Comments
	Assumed risk	Corresponding risk				
	Control	Alpha blocker versus placebo or control				
Ability to void spontaneously after TWOC without the need for re-catheterisation	Study population		RR 1.55 (1.36 to 1.76)	1044 (9 studies)	⊕⊕⊕⊖ moderate ^{1,2}	
	383 per 1000	582 per 1000 (509 to 666)

Cost effectiveness - <u>not reported</u>	See comment	See comment	Not estimable	-	See comment	
Number with adverse effects	Study population		RR 1.2 (0.74 to 1.95)	657 (4 studies)	⊕⊕⊖⊖ low ^{2,4}	
	74 per 1000	89 per 1000 (55 to 145)				

*The basis for the **assumed risk** (e.g. the median control group risk across studies) is provided in footnotes. The **corresponding risk** (and its 95% confidence interval) is based on the assumed risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

CI: Confidence interval; **RR:** Risk ratio; **QoL:** quality of life; **TWOC:** trial without catheter

GRADE Working Group grades of evidence

High quality: Further research is very unlikely to change our confidence in the estimate of effect.

Moderate quality: Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.

Low quality: Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.

Very low quality: We are very uncertain about the estimate.

- 1 Random sequence generation unclear in 4 studies and high risk in 1 study. Allocation concealment unclear in 6 studies and high risk in 1 study.
- 2 A minimum of ten trials are required to assess for publication bias.
- 3 Random sequence generation unclear in 3 studies and high risk in 1 study. Allocation concealment unclear in 5 studies and high risk in 1 study.
- 4 Wide 95% confidence interval: RR 1.20 (95% CI 0.74 to 1.95)

BACKGROUND

Description of the condition

According to International Continence Society, urinary retention is defined as the inability to pass urine despite persistent effort (Haylen 2010). Acute urinary retention in men is a urological emergency. It is characterised by a sudden and often very painful inability to pass urine. The standard first-line management is bladder catheterisation (insertion of a drainage tube into the bladder). Reported incidence rates of acute urinary retention vary from 0.4% to 25% per year in men seen in urological practice every year (Schulman 2001). One large US cohort study estimated the risk of a retention episode at 23% for a 60-year old male if he lived for another 20 years (Jacobsen 1997). The incidence of acute urinary retention in the overall male population is low. It increases with age and various studies have reported incidence rates ranging from 2.2 to 6.8 out of 1000 man-years in the general male population (Jacobsen 1997; Meigs 1999; Temml 2003; Verhamme 2005). This rises to 17 to 25 in 1000 man-years in men with lower urinary tract symptoms (LUTS) presumed secondary to benign prostatic enlargement (BPE) (Barry 1997; McConnell 1998; Roerborn 2000). It has been claimed that emergency admissions due to retention have a larger adverse impact on patients' health-related quality of life than emergency admissions for renal colic or elective admission for surgery for LUTS or BPE. This is mainly due to the higher number of investigations and recurrent emergency attendances in the acute urinary retention group compared to the other two groups (Thomas 2005).

The causes of acute urinary retention can be classified into three categories. The first one is characterised by any condition that causes an increased resistance to urinary flow (for example, BPE, bladder neck stenosis, urethral stricture). The second category is characterised by weakness of the detrusor muscle or interruption of the sensory bladder innervation (for example, spinal cord injuries, neurological disorders such as multiple sclerosis). The third category is caused by any event leading to bladder overdistention (for example, following surgery or as a side effect of drug treatment) (Emberton 1999). Retention is also commonly associated with urinary tract infection.

The definitive treatment depends on the underlying cause. The principal aim of treatment is to restore spontaneous voiding without the need for re-catheterisation and, by doing so, avoiding the risk of catheter-related complications (such as causing a false urethral passage, infection, pain, haematuria (blood in the urine), urethral stricture formation) and worsening renal function (acute or chronic renal failure) to improve quality of life. Catheters are either introduced by the transurethral or suprapubic route and can be used short term, long term or intermittently.

Description of the intervention

There are three approaches to treatment once symptoms have been controlled by bladder catheterisation.

1. The first is early surgery, such as transurethral resection of the prostate, within a few days or semi-elective within a few weeks of the first episode of retention. Surgery carries the risk of bleeding, infection, retrograde ejaculation, erectile dysfunction, urinary incontinence, treatment failure and recurrence of lower urinary tract symptoms (Omar 2014).

2. The second approach is long-term catheterisation, using either an in-dwelling transurethral or suprapubic catheter, or intermittent catheterisation. This approach has disadvantages such as urinary tract infection (Niël-Weise 2005).
3. The third option is to remove the catheter again to see whether normal micturition resumes, a trial without catheter (TWOC). This can be done in an ambulant or in-patient hospital setting.

Success rates reported for TWOC in observational studies range from 23% to 28% (Murray 1984; Taube 1989a). Failure requires re-catheterisation and re-assessment of future management options, such as prostate surgery or long-term catheterisation. There are advantages both for the patient and healthcare system from a successful trial period without a catheter. Apart from not having to spend time with a catheter at home, successful resumption of voiding could mean delaying or ideally avoiding the need for surgery. It has also been shown that surgery, where necessary, is safer in the absence of an indwelling catheter (Pickard 1998).

How the intervention might work

Any intervention which aims to increase the rate of successful TWOC following an acute urinary retention episode is considered potentially beneficial. Alpha1-adrenoreceptors are highly prevalent in the prostate and bladder neck (Caine 1975; Caine 1987). The principle behind the use of alpha1-adrenoreceptor antagonists (alpha1 blockers) is that they reduce prostatic smooth muscle tone and thus resistance to urinary flow (Fulton 1995). This should result in an improvement of urinary symptoms. Caine and colleagues suggested that alpha blockers could improve the chances of successful TWOC, assuming there is adequate detrusor function (Caine 1976). However, their wide use at that time was restricted mainly because of cardiovascular side effects. Functionally more uroselective agents have been developed. Alpha1 blockers such as alfuzosin, doxazosin, indoramin, prazosin, silodosin, tamsulosin and terazosin are commonly used as first-line treatment for lower urinary tract symptoms associated with BPE.

Despite their greater selectivity, alpha1 blockers can still interact with many other drugs. Their main pharmacological adverse effect, apart from retrograde ejaculation, remains an additive or enhancing hypotensive effect especially when used with other antihypertensive drugs. Known adverse effects include drowsiness, (postural) hypotension, syncope, asthenia, depression, headache, dry mouth, nausea, vomiting, diarrhoea, constipation (gastro-intestinal disturbances), oedema, blurred vision, rhinitis, erectile disorders (including priapism), tachycardia and palpitations. They should, therefore, be avoided in patients with a history of postural hypotension and micturition syncope. Patients on antihypertensive treatment may require reduced dosage. Alpha blockers are also associated with hypersensitivity reactions including rash, pruritus and angioedema. Caution is advised in elderly patients and those with hepatic or severe renal impairment. Caution is also in elderly people undergoing cataract surgery as there is risk of intra-operative floppy iris syndrome (most strongly associated with tamsulosin) (BNF December 2013).

Why it is important to do this review

A systematic review of the available evidence from randomised controlled trials (RCTs), periodically updated, is needed to find out whether alpha blockers improve the chances of successful TWOC.

OBJECTIVES

To assess the effectiveness of alpha blockers on successful resumption of micturition following removal of a urethral urinary catheter after an episode of acute urinary retention in men. In the absence of internationally agreed outcome measures for the success of a trial without catheter (TWOC), success was defined as the return to satisfactory voiding without need for re-catheterisation within 24 hours.

METHODS

Criteria for considering studies for this review

Types of studies

All randomised and quasi-randomised controlled trials (Higgins 2011) of alpha blockers for TWOC after acute urinary retention in men.

Types of participants

Adult men of any age who needed to be catheterised transurethrally because of an episode of acute urinary retention.

Types of interventions

At least one trial group managed with alpha blockers versus any other type of management. Other types of management included placebo or no treatment, or other active treatments such as another alpha blocker.

The following comparisons were addressed:

1. an alpha blocker versus placebo or no treatment;
2. one alpha blocker versus another alpha blocker;
3. an alpha blocker versus another active treatment.

Types of outcome measures

Primary outcomes

1. Ability to void spontaneously after TWOC without the need for re-catheterisation
2. Incidence of recurrent urinary retention
3. Need for prostatic surgery
4. Adverse effects of alpha blockers
5. Condition-specific quality of life measures (e.g. IPSS (International Prostate Symptom Score)) (Batista-Miranda 1995)
6. Cost effectiveness

These six outcomes were considered 'critical' for the purpose of analysis using GRADE.

Secondary outcomes

1. Drop-out/discontinuation rates (due to adverse effects or lack of therapeutic effect)
2. Persistent lower urinary tract symptoms (LUTS)
3. Quality of life (QoL) (psychological)
4. General quality of life health measures (e.g. SF12, SF36 questionnaires)

Quality of evidence

The quality of evidence was assessed using the Grading of Recommendations Assessment, Development and Evaluation (GRADE) (Guyatt 2011; Guyatt 2011a; Guyatt 2013a; Guyatt 2013b). The following five domains were assessed for evaluating the quality of evidence.

1. Limitations of study design
2. Inconsistency of results
3. Indirectness of evidence
4. Imprecision of measurements
5. Publication bias

The primary outcomes listed above were categorised as 'critical' for decision-making from the male patient's perspective: the remaining secondary outcomes were categorised as 'important' or 'not important'. Evidence related to outcomes deemed 'critical' was then rated as high, moderate, low or very low quality. This rating indicates confidence in the accuracy of the measured effect of intervention compared to the true effect. The quality of evidence was downgraded if the randomisation process (random sequence generation and allocation concealment) of the trial was considered to be inadequate and/or if the effect estimate crossed the line of 'no effect' on either side by 25% or 50% (i.e. an effect estimate with a wide confidence interval). Further reasons to downgrade were if findings between trials were inconsistent or if trials measured outcomes not directly corresponding to the pre-specified review outcomes. Publication bias was only assessed if there were 10 or more trials. The GRADE working group recommended including up to seven critical outcomes in a systematic review. Quality of evidence was assessed for all primary outcomes if reported (Guyatt 2011; Guyatt 2011a; Guyatt 2013a; Guyatt 2013b).

Search methods for identification of studies

We did not impose any language or other restrictions on the searches.

Electronic searches

This review has drawn on the search strategy developed for the Cochrane Incontinence Review Group. Relevant trials were identified from the Group's Specialised Register of controlled trials which is described, along with the group search strategy, under the Incontinence Group's module in *The Cochrane Library*. The register contains trials identified from the Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE, MEDLINE in process, and handsearching of journals and conference proceedings. The Incontinence Group Specialised Register was searched using the Group's own keyword system. The date of the last search was 9 October 2013.

The terms used to search the Incontinence Group Specialised Register are given below.

```
{(DESIGN.CCT*) OR {DESIGN.RCT*}}
```

AND

```
{(INTVENT.MECH.CATH.TrialOffCatheter.prostate.) OR  
{INTVENT.MECH.CATH.trialWithoutCath.}}
```

(All searches were of the keyword field of Reference Manager 2012).

For the current version of the review the following databases were also searched (all on OVID SP), the date of the last search for all except CENTRAL was 4 June 2013. The search terms are given in [Appendix 1](#):

- **CENTRAL** (2013, Issue 5) was last searched on 5 June 2013
- **MEDLINE** 1946 to May Week 4 2013
- **MEDLINE in Process** (covering to 3 June 2013)
- **EMBASE Classic** and **EMBASE** 1947 to 2013 Week 22

For the original version of this review ([Zeif 2009](#)) extra, specific searches were performed. For details of this search please see [Appendix 2](#).

Searching other resources

The reference lists of relevant articles were checked for other potentially relevant trial reports.

Data collection and analysis

Selection of studies

Only randomised or quasi-randomised trials were included in this systematic review. Two review authors (EF and MO) independently

examined all the citations and abstracts derived from the search strategy. Full reports of potentially relevant trials were then retrieved and examined independently for eligibility in the same manner. Review authors were not blinded to the names of the trials' authors, institutions or the journals. We contacted authors of trials under consideration for additional information when required. Trials in languages other than English were translated as appropriate. Any disagreement about trial selection and inclusion was resolved by discussion. An independent judgment was sought where disagreement persisted. Excluded studies considered formally for this review were also listed along with reasons for their exclusion. Studies were excluded from the review if they were not randomised or quasi-randomised controlled trials of treatment with alpha blockers for urinary retention, or if they made comparisons other than those pre-specified. Trials were also excluded if the participants were not relevant.

The process of trial selection is documented in a PRISMA flow chart ([Figure 1](#)).

Figure 1. PRISMA study flow diagram

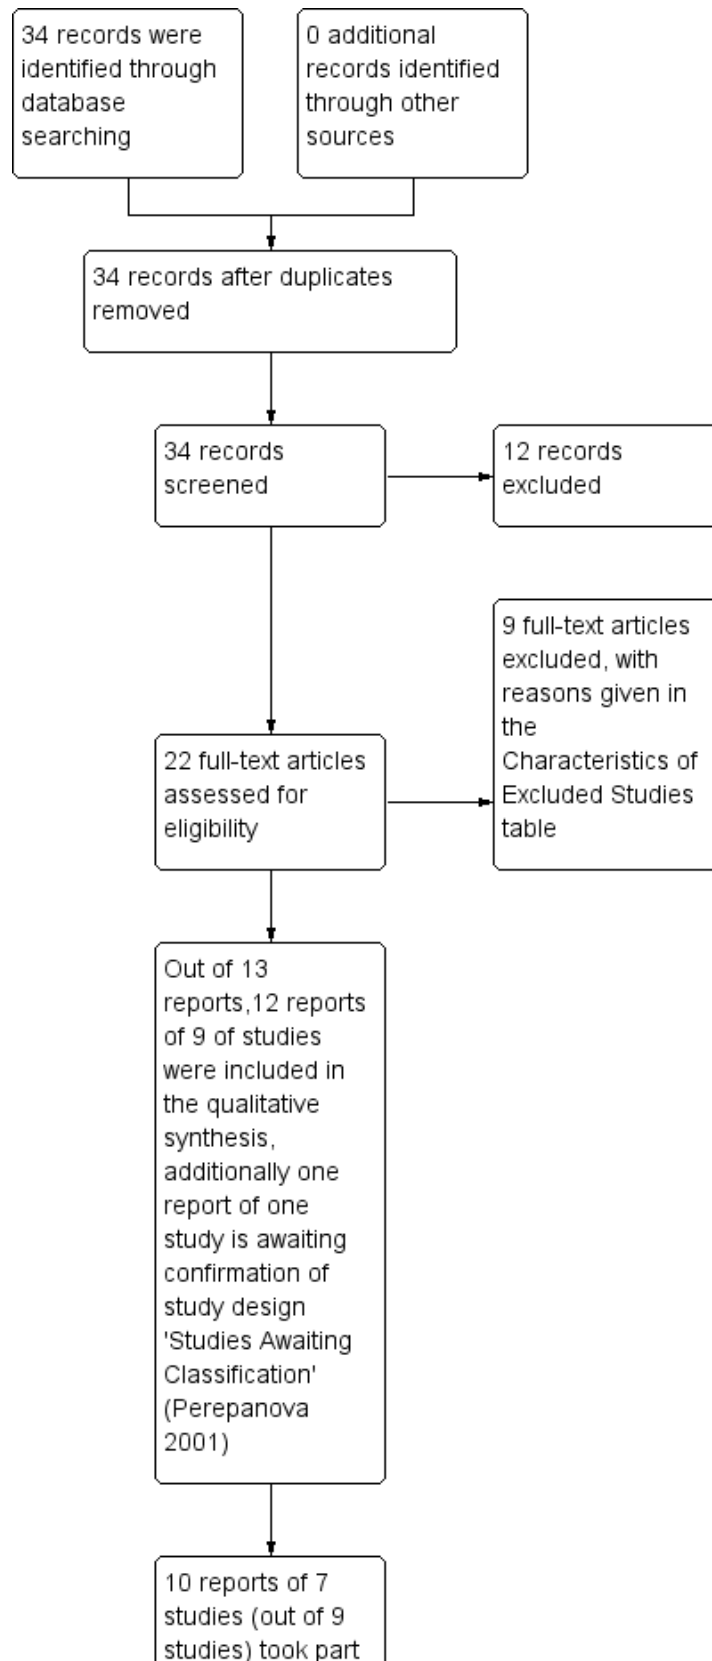

Figure 1. (Continued)

studies (out of 9 studies) took part in quantitative synthesis (meta-analysis)

Data extraction and management

Two review authors (EF and MO) independently extracted data from included trials using a standardised form. Any differences of opinion relating to study inclusion, methodological flaws or data extraction were resolved by discussion among the review authors and, when necessary, were referred for independent arbitration. Trial authors were contacted when there was insufficient information. All data entry was done using Review Manager software (RevMan 5.2). Quality of evidence was assessed by adopting GRADE approach by two review authors (EF and MO) using GRADEpro software. Data from included trials were processed according to the *Cochrane Handbook for Systematic Reviews of Interventions* (Higgins 2011).

Assessment of risk of bias in included studies

The Cochrane 'Risk of bias' assessment tool (Higgins 2011) was used to assess the risk of bias in included trials. Domains of bias included the following.

- Sequence generation
- Allocation concealment
- Blinding of participants or staff
- Blinding of outcome assessors
- Incomplete outcome data
- Selective reporting of outcomes
- Any other potential sources of bias

These domains were independently assessed by two review authors. Any difference of opinion was resolved by discussion. Where disagreement persisted, a third party was consulted.

Measures of treatment effect

The analyses in this systematic review were based upon available data from all included trials relevant to the comparisons and outcomes being studied. When trials were reported in multiple publications, only the most current or complete data were included for each outcome. When appropriate, meta-analysis was performed using a fixed-effect model for calculation of pooled estimates and their 95% confidence intervals (CI).

For categorical outcomes, the number of participants reporting an outcome was related to the number at risk in each group to derive the risk ratio (RR). If continuous variables had been identified, we planned to use the mean and standard deviation to derive a mean difference. For similar outcomes reported using different scales, the standard mean difference (SMD) would have been calculated. When data used to calculate RRs were unavailable, the most detailed available numerical data were used to calculate actual numbers or mean and standard deviations (e.g. P values). Differences between trials were further investigated when significant heterogeneity was found or appeared obvious from visual inspection of the results.

Unit of analysis issues

Analysis of the primary outcome was per man randomised.

Dealing with missing data

As far as possible, data were analysed on an "intention-to-treat" basis, so that participants were analysed in the groups to which they were originally randomised. Trials which did not do this were considered for exclusion. In the case of missing data, attempts were made to obtain these from the original trialists (see [Acknowledgements](#)). Data were reported as shown in the trials if this was possible except in the case of evidence of differential loss to follow-up, for which imputation of missing data was considered.

Assessment of heterogeneity

Only trials deemed clinically similar were combined. Heterogeneity between trials was evaluated by visual inspection of forest plots and the I^2 test. Thresholds for interpretation of the I^2 test were defined according to the *Cochrane Handbook for Systematic Reviews of Interventions* (Higgins 2011).

Assessment of reporting biases

In light of the difficulties associated with the detection of, and correction for, publication bias and other biases, the authors strived to minimise their impact by ensuring a fully comprehensive search strategy was used and by monitoring for duplication of data.

Data synthesis

Trials were combined for analysis of similar interventions based upon clinical criteria.

Subgroup analysis and investigation of heterogeneity

Data were subgrouped by the type of alpha blocker received by participants.

- Alfuzosin
- Tamsulosin
- Doxazosin
- Silodosin

Test for subgroup differences was carried out with Chi^2 and I^2 tests.

If heterogeneity between trials was evident, we planned investigation to identify its causes.

Sensitivity analysis

We planned to perform sensitivity analyses to determine the effects of including or excluding trials at high risk of bias, but this was not possible due to lack of trials.

RESULTS

Description of studies

Full characteristics of the trials are presented in the tables 'Characteristics of included studies' and 'Characteristics of excluded studies'.

Results of the search

The literature search resulted in 34 records to assess. The flow of literature through the assessment process is shown in the PRISMA flowchart (Figure 1).

Included studies

Nine randomised controlled trials were included in the systematic review. The trials involved a total of 1044 men who received either an alpha blocker, placebo or no treatment for one to three days in six trials, a maximum of eight days in one trial and 32 days in the other trial, before trial without catheter (TWOC) following an acute urinary retention episode. The number of study participants in each trial ranged from 44 to 360. The trials were conducted in China, India, Singapore, Spain, the UK and USA.

- Five trials compared alfuzosin versus placebo (Agrawal 2009; McNeill 1999; McNeill 2005; Shah 2002; Tiong 2009).
- Two trials compared tamsulosin versus placebo (Agrawal 2009; Lucas 2005).
- One trial compared tamsulosin versus no treatment (Hua 2003).
- One trial compared doxazosin versus no treatment (Prieto 2008).
- One trial compared silodosin versus placebo (Kumar 2013).

The primary endpoint of what constitutes successful TWOC was defined differently by the trialists, reflecting the lack of internationally agreed outcome measures.

- Agrawal 2009 and Prieto 2008 defined it simply as the return to satisfactory voiding after catheter removal.
- No definition was given by Hua 2003 and McNeill 1999.
- McNeill 2005 defined successful TWOC as the return to satisfactory voiding without a need for re-catheterisation within 24 hours.
- Shah and colleagues (Shah 2002) defined it as the ability to void with a residual volume of 200 mL or less
- Lucas 2005 used a flow rate greater than 5 mL/sec with a voided volume of greater than 100 mL and residual volume of 200 mL or less.
- Tiong 2009 and Kumar 2013 defined it as successful voiding with a post void residual volume of less than 150 mL.

The trials used a variety of outcome measures. Apart from successful TWOC, these included:

- prevention of recurrent urinary retention after successful TWOC (Lucas 2005; McNeill 2005; Shah 2002);
- need for prostatic surgery (Agrawal 2009; McNeill 2005; Shah 2002);
- persistent lower urinary tract symptoms (McNeill 2005);
- post-void residual volumes (McNeill 1999);
- condition-specific QoL (IPSS scores) (McNeill 2005);

- alpha blocker adverse effects (Lucas 2005; McNeill 1999; McNeill 2005; Tiong 2009);
- alpha blocker serious adverse effects (McNeill 2005);
- maximum urinary flow rate (Qmax) (Agrawal 2009; Prieto 2008);
- drop-out rates (Lucas 2005; McNeill 1999; McNeill 2005; Prieto 2008; Tiong 2009).

None of the eligible trials addressed outcome measures such as spontaneously voided volume, cost effectiveness, improvement in QoL (other than condition-specific QoL as assessed by IPSS score) or general health measures (for example SF12 or SF36 questionnaires).

Excluded studies

Nine studies were excluded (Joo 2008; Kraus 2010; Lim 1999; Liu 2009; Lorente 2004; Martov 2010; McNeill 2004; Taube 1989b; Wang 2009). One study involved elective catheterisation prior to spinal surgery (Joo 2008). Four studies did not involve use of a catheter (Kraus 2010; Liu 2009; Martov 2010; Wang 2009). Two studies addressed TWOC in patients without any alpha blocker or other treatment (Lim 1999; Taube 1989b), and one study used increasing dosages of alpha blocker in failed TWOC patients (Lorente 2004). One study involved long-term follow-up of patients who had previously had successful TWOC (McNeill 2004).

A 2006 report detailing preliminary results of a trial had been originally included in this review but was superseded by a full publication (Tiong 2009).

Lack of clarity regarding the process of randomisation in one trial (Perepanova 2001) meant that we needed to contact the trialists for additional information. This study was therefore moved into the 'Characteristics of studies awaiting classification' section pending a response.

Risk of bias in included studies

Allocation

Random sequence generation

Four of the included trials clearly described the method of randomisation. These were done by computer-based randomisation in three trials (Kumar 2013; McNeill 1999; Tiong 2009) and in one trial by a 'centrally established randomization list' (McNeill 2005). Four trials did not adequately specify their methods of randomisation (Agrawal 2009; Hua 2003; Lucas 2005; Shah 2002), and one study (Prieto 2008) was deemed high risk (quasi-randomised) due to the allocation of patients by year of birth (odd years versus even).

Concealment of allocation

Methods of allocation concealment were inadequately described in six of the included trials (Agrawal 2009; Hua 2003; Kumar 2013; Lucas 2005; McNeill 2005; Shah 2002). One low risk study (McNeill 1999) used a 'sealed copy of the code' to conceal randomisation and another stated that allocation was blinded (Tiong 2009). One study (Prieto 2008) was deemed high risk as allocation concealment was judged to be highly unlikely given the method of randomisation (described above, quasi-randomised).

Blinding

Blinding of participants and personnel (performance bias)

Blinding of participants and personnel was adequately described in four trials (Lucas 2005; McNeill 1999; McNeill 2005; Tiong 2009), one of which (McNeill 1999) stating that a central pharmacy 'packaged the SR alfuzosin and placebo to appear identical'. This aspect of study design was not adequately described in a further four trials (Agrawal 2009; Hua 2003; Kumar 2013; Shah 2002), and in one trial (Prieto 2008) was deemed to be high risk due to the method of randomisation (described earlier, quasi-randomised).

Blinding of outcome assessors (detection bias)

None of the included trials (Agrawal 2009; Hua 2003; Kumar 2013; Lucas 2005; McNeill 1999; McNeill 2005; Prieto 2008; Shah 2002; Tiong 2009) gave details of blinding of outcome assessment. Therefore all these trials were judged as "unclear" risk of bias for this domain.

Incomplete outcome data

Seven of the included trials were classified as low risk for incomplete outcome data (Hua 2003; Kumar 2013; Lucas 2005; McNeill 1999; Prieto 2008; Shah 2002; Tiong 2009). It was unclear in one trial (Agrawal 2009) if data were complete due to lack of detail in tables of analysis. One trial was classified high risk due to incomplete data for three patients (McNeill 2005).

Selective reporting

Due to lack of availability of the study protocols, it was not clear if selective reporting was present in any of the included trials (Agrawal 2009; Hua 2003; Kumar 2013; Lucas 2005; McNeill 1999; McNeill 2005; Prieto 2008; Shah 2002; Tiong 2009).

Other potential sources of bias

Two trials (Kumar 2013; Tiong 2009) were classified as low risk of other bias, two trials (Agrawal 2009; Hua 2003) as unclear risk, and five trials (Lucas 2005; McNeill 1999; McNeill 2005; Prieto 2008; Shah 2002) as high risk. Both Kumar 2013 and Tiong 2009 had comparable groups at baseline, had obtained ethical approval and informed consent and had a low withdrawal rate/no withdrawals at all and were judged at low risk of bias. The trials deemed unclear risk did not adequately explain such aspects of study design. All trials deemed high risk received financial support from pharmaceutical companies. Further reasons for this classification included lack of baseline comparability in trials groups (McNeill 1999), lack of justification for reporting both intention-to-treat and per-protocol analyses (McNeill 2005), and inconsistencies in description of trial interventions (Prieto 2008).

Detailed results of the 'Risk of bias' assessment are provided in Figure 2 and Figure 3.

Figure 2. 'Risk of bias' graph: review authors' judgements about each risk of bias item presented as percentages across all included studies.

Figure 3. 'Risk of bias' summary: review authors' judgements about each risk of bias item for each included study.

Effects of interventions

See: [Summary of findings for the main comparison Alpha blocker versus placebo or control for acute urinary retention in adult men](#)

Nine randomised controlled trials met the inclusion criteria for this review (Agrawal 2009; Hua 2003; Kumar 2013; Lucas 2005; McNeill 1999; McNeill 2005; Prieto 2008; Shah 2002; Tiong 2009). All compared alpha blockers versus placebo. Five trials tested alfuzosin (Agrawal 2009; McNeill 1999; McNeill 2005; Shah 2002; Tiong 2009), three trials tested tamsulosin (Agrawal 2009; Hua 2003; Lucas 2005), one trial tested doxazosin (Prieto 2008) and one trial tested silodosin (Kumar 2013).

Primary outcomes

We applied GRADE to all these primary outcomes and the results are summarised in the [Summary of findings for the main comparison](#).

Ability to void spontaneously after trial without catheter (TWOC)

All nine trials reported this outcome (Agrawal 2009; Hua 2003; Kumar 2013; Lucas 2005; McNeill 1999; McNeill 2005; Prieto 2008; Tiong 2009; Shah 2002). There was moderate quality evidence that the usage of alpha blockers was better compared to placebo (366/608, 60.2% of men using an alpha blocker were able to void spontaneously after catheter removal compared with 185/486, 38.1% using placebo, risk ratio (RR) 1.55, 95% confidence interval (CI) 1.36 to 1.76) (Analysis 1.1).

On subgroup analysis based upon individual drugs, three types of alpha blockers were statistically significantly better than placebo: alfuzosin RR 1.40 (95% CI 1.19 to 1.64); tamsulosin RR 1.97 (95% CI 1.49 to 2.59); and silodosin RR 2.09 (1.26 to 3.48) (Analysis 1.1). The only trial to investigate doxazosin versus no medication (Prieto 2008) did not show a statistically significant difference (RR 1.09, 0.66 to 1.81, Analysis 1.1.3), but the confidence interval was wide and the trial was small.

Incidence of recurrent acute urinary retention

Eight trials reported this outcome (Agrawal 2009; Kumar 2013; Lucas 2005; McNeill 1999; McNeill 2005; Prieto 2008; Shah 2002; Tiong 2009). There was moderate quality evidence that alpha blockers were effective in reducing the chance of recurrent urinary retention (204/573, 35.6% of men had a further episode of retention after alpha blocker use compared with 228/450, 50.7% after control, RR 0.69, 95% CI 0.60 to 0.79) (Analysis 1.2).

On subgroup analysis based upon individual drugs, statistically significant differences were found to favour three of the drugs trialled (alfuzosin: RR 0.72, 95% CI 0.60 to 0.85; tamsulosin: RR 0.66, 95% CI 0.50 to 0.87; silodosin: RR 0.37, 95% CI 0.18 to 0.74). Only one trial (Prieto 2008) investigated doxazosin and found no difference compared with patients who received no treatment, though the confidence intervals were wide (RR 0.98, 95% CI 0.65 to 1.48)

Three other trials (McNeill 2005; Shah 2002; Tiong 2009) reported recurrent retention (relapse) after successful TWOC but this was carried out during the second phases of the trials after both successful alpha blocker and placebo participants were either re-randomised or continued on alpha blocker treatment. Therefore, these data could not be used for analysis in this review.

Need for prostatic surgery

Although reported in three trials (McNeill 1999; McNeill 2005; Shah 2002), this outcome measure could not be assessed due to the fact that participants of both the alpha blocker and placebo groups were pooled together in one group following successful TWOC and either randomised again (McNeill 2005), openly followed up (McNeill 1999) or continued (or commenced) on alpha blocker treatment (Shah 2002).

Adverse effects of alpha blockers

Adverse effects described included dizziness, somnolence, fainting, headache, postural hypotension or hypotension, malaise, retrograde ejaculation and syncope. Five trials (Lucas 2005; McNeill 1999; McNeill 2005; Prieto 2008; Tiong 2009) reported this outcome (Analysis 1.3). No statistically significant difference was found in the incidence of adverse effects between alpha blockers and control overall (RR 1.19, 95% CI 0.75 to 1.89), with non-significant findings also on subgroup analysis (alfuzosin: RR 0.91, 95% CI 0.53 to 1.54; tamsulosin: RR 2.71, 95% CI 0.90 to 8.14); doxazosin: RR 3.13, 95% CI 0.13 to 73.01, though this evidence was of low quality.

Serious adverse effects of alpha blockers

Only one trial (McNeill 2005) mentioned serious alpha blocker adverse effects but did not specify what constituted a 'serious' effect. The number of events was small (3/238 with alfuzosin versus 2/122 with placebo) and the difference was not statistically significant (RR 0.77, 95% CI 0.13 to 4.54) (Analysis 1.4).

Improvement in condition-specific QoL (IPSS and bother score)

Two trials (Kumar 2013; McNeill 2005) reported IPSS scores.

- An improvement was described in mean IPSS score with alfuzosin treatment compared with placebo (McNeill 2005) (IPSS: alpha blocker 8.75 versus placebo 11.45, $P = 0.012$; bother score: alpha blocker 1.66 versus placebo 2.27, $P = 0.004$), although these patients had been re-randomised after a successful TWOC.
- Patients treated with silodosin (Kumar 2013) showed an improvement in mean IPSS scores at TWOC (TWOC: silodosin 25.7 +/- 2.5 versus placebo 24.9 +/- 1.8, $P = 0.02$).

In both trials, IPSS scores were only collected in those men who had a successful TWOC. These data were therefore not relevant to the analyses of this review, and the quality of evidence could not be estimated.

Cost effectiveness

No trials reported any information about cost effectiveness.

Secondary outcomes:

The following secondary outcomes were reported in the included trials.

Drop-out/discontinuation rates (due to adverse effects or lack of therapeutic effect)

Five trials described drop-out rates due to alpha blocker side effects involving alfuzosin, tamsulosin and doxazosin (Lucas 2005; McNeill 1999; McNeill 2005; Prieto 2008; Tiong 2009). There were lower drop-out rates for placebo compared to alpha blocker treatment with a statistically significant outcome in favour of placebo (RR

3.94, 95% CI 1.28 to 12.12) ([Analysis 1.5](#)). Subgroup analysis showed no statistically significant difference for individual drugs however (alfuzosin: RR 2.83, 95% CI 0.62 to 12.93; tamsulosin: RR 6.91, 95% CI 0.87 to 54.76; doxazosin: RR 3.13, 95% CI 0.13 to 73.01).

Persistent lower urinary tract symptoms (LUTS)

In the second phase (re-randomisation of successful TWOC patients) of a trial ([McNeill 2005](#)), a significant improvement of LUTS was described with alpha blocker treatment compared with placebo at six months follow-up (IPSS 8.75 versus 11.45, $P = 0.012$; bother score 1.66 versus 2.27, $P = 0.004$). Due to re-randomisation, we could not use this data as part of our pre-defined secondary outcomes.

DISCUSSION

This systematic review suggests that some alpha blockers may help men by increasing the rate of successful trial without catheter (TWOC) after an acute urinary retention episode. However, the current evidence is limited in terms of the number of trials and participants. A major limitation of this review is the lack of standardisation of the definition of a successful TWOC. When is a TWOC considered successful? Does it depend on maximum flow rate, residual volume, or both? Or is it simply no need for re-catheterisation within 24 hours? Does re-catheterisation after two or three days following a successful TWOC constitute a failed trial or is it recurrent urinary retention, that is a new event?

Costs and cost effectiveness of alpha blocker treatment is important for both patients and healthcare providers. It would probably make little sense if alpha blockers only delayed prostate surgery for a few months, with the added cost and distress of going back into retention. Because this outcome was not reported in the trials, this review was unable to answer whether alpha blockers before catheter removal are cost effective in this clinical scenario. A few trials tried to address these issues but we could not assess the information as part of a meta-analysis because men had been treated both with the active drug and a placebo. A review of the literature showed one retrospective study from Belgium that evaluated costs for the first six months after a failed TWOC following a first episode of acute urinary retention ([Lamotte 2005](#)). No alpha blockers were used in the study, which came to the conclusion that delayed transurethral resection of the prostate (TURP) during a subsequent or scheduled hospitalisation was less expensive compared to TURP performed during the initial emergency hospital admission.

A follow-on study to [McNeill 2005](#) examined whether use of alfuzosin during hospitalisation for acute urinary retention and for six months after successful TWOC was cost effective compared to placebo and immediate prostatectomy ([Annemans 2005](#)). Alfuzosin treatment was associated with a lower rate of prostatectomy after hospital discharge following successful TWOC. Alfuzosin treatment generated cost savings of £349 relative to placebo and £892 relative to immediate prostatectomy (both statistically significant, $P < 0.05$). However, this is limited evidence considering the possible implications of this important issue.

Another unanswered question is how long alpha blockers should be continued after successful TWOC? If future trials reporting on longer-term outcomes suggest that most men on alpha blockers end up having prostate surgery within one year, then this could

lead to a change in management strategy where men could be listed for prostate surgery regardless of a successful TWOC. In order to answer these questions, rigorous well-designed randomised controlled trials, which use the recommendations set out in the CONSORT statement and reporting all critical outcomes, are required.

Summary of main results

The critical outcomes were assessed using the GRADE approach. There was moderate quality evidence that alpha blockers increase success rates of a trial without a catheter. There was low quality evidence that alpha blockers may reduce the risk of recurrent urinary retention. There was insufficient evidence to determine whether the use of alpha blockers reduces the need for prostatic surgery. The effects on QoL, cost effectiveness and recommended duration of alpha blocker treatment after successful trial without catheter remain unknown, as these outcomes were not reported.

Overall completeness and applicability of evidence

Four of the pre-specified primary outcomes were reported. All of the included trials reported successful TWOC though only three trials addressed incidence of recurrent acute urinary retention directly ([Agrawal 2009](#); [Lucas 2005](#); [Prieto 2008](#)). Only one of these reported any useable data on long-term outcomes according to original allocation status ([Prieto 2008](#)). Other trials reported need for re-catheterisation as a TWOC failure endpoint ([Agrawal 2009](#); [Kumar 2013](#); [Lucas 2005](#); [McNeill 1999](#); [McNeill 2005](#); [Prieto 2008](#); [Shah 2002](#); [Tiong 2009](#)). We therefore combined these data by considering need for re-catheterisation following TWOC as a surrogate marker of relapse of acute urinary retention.

Four trials also addressed the issue of adverse effects due to alpha blocker treatment ([Lucas 2005](#); [McNeill 1999](#); [McNeill 2005](#); [Tiong 2009](#)), with one trial ([McNeill 2005](#)) reporting serious (but undefined) adverse effects. Five trials reported drop out due to adverse effects ([Lucas 2005](#); [McNeill 1999](#); [McNeill 2005](#); [Prieto 2008](#); [Tiong 2009](#)) but these were rare (less than 5% of men on active treatment).

A condition-specific quality of life measure (IPSS score) was also reported by two trials ([Kumar 2013](#); [McNeill 2005](#)) but the data were only reported in men who had had a successful TWOC, so were not relevant to a comparison between the groups. Other generic measures of quality of life (e.g. SF36) were not reported by any of the included trials.

None of the included trials reported useable data regarding the need for further surgery according to original allocation status. Similarly, other pre-specified secondary outcomes including urinary flow rate, cost effectiveness or costs were not reported. The incidence of LUTS was reported in the second phase of one trial ([McNeill 2005](#)), though again the data were not usable.

Quality of the evidence

The assessment of trial methodology is crucial in determining the quality of the estimated size of treatment effects of all interventions. In this review, methodological flaws of the included trials were assessed using the reports of the trials. Quality of reporting was therefore fundamental to our judgement of methodological quality and quality of effect estimates. None of the reported outcomes deemed 'critical' were assessed to be of high

quality, with one outcome deemed moderate quality and two low quality. The quality of evidence of three of the 'critical' outcomes were not estimable.

Potential biases in the review process

Every effort was made to ensure adherence to the methodological framework set out in the *Cochrane Handbook for Systematic Reviews of Intervention* (Higgins 2011). We were nevertheless mindful of potential biases which may enter into the review process and endeavoured to correct these where possible. We ensured that the entire process (such as abstract and full text screening) was done independently by two review authors. An independent third party was involved in case of disagreement in order to minimise potential bias in the review process.

Agreements and disagreements with other studies or reviews

The review authors are unaware of any similar review relating to the subject investigated.

AUTHORS' CONCLUSIONS

Implications for practice

Results from this review suggest that administration of an alpha blocker during trial without catheter (TWOC) for adult men catheterised for acute urinary retention may be of benefit in decreasing rates of recurrent acute urinary retention relative to control. The incidence of adverse effects appears to be low. However, the data in this review are limited due to the large amount of unpublished data that was not available to us (Ramirez 2014).

Implications for research

There is an urgent need for standardisation of the definition of what constitutes a successful TWOC for future studies. More randomised controlled trials are needed to assess whether alpha blocker treatment is beneficial for successful TWOC, prevents recurrent urinary retention and whether it reduces the need for prostatic surgery. Furthermore, long-term follow-up studies in which patients with successful TWOC are maintained on the allocated intervention are needed to determine if they are worthwhile in the longer term. Other questions to be answered are cost effectiveness and the duration of alpha blocker treatment after TWOC.

As the majority of the identified trials were single centred, therefore, future trials should be large, adequately powered and multi-centred. The trials should include outcomes which are critical from patients' perspective and which should also abide by the principles and recommendations of the CONSORT guideline.

ACKNOWLEDGEMENTS

The review authors would like to acknowledge Hans-Joerg Zeif for his contribution to the first version of the review (Zeif 2009). Our sincere gratitude goes to Malik Mukhitdinov for his services in translation of a Russian study (Perepanova 2001) and for the kind responses of the trial authors Dr Luis Prieto Chaparro and Dr Marlon Jay Tibung to our questions. We would also like to express our thanks to the members of the Cochrane Incontinence Review Group.

CHARACTERISTICS OF STUDIES
Characteristics of included studies [ordered by study ID]
Agrawal 2009

Methods	Prospective, randomised, placebo-controlled, single centre study
---------	--

Agrawal 2009 (Continued)

Participants	150 patients (50 alfuzosin, 50 tamsulosin, 50 placebo), mean age 69, 72 and 71 years respectively (aged 48 to 90 years)
Interventions	A (50): Alfuzosin 10 mg OD B (50): Tamsulosin 0.4 mg C (50): Placebo, Then TWOC after 3 days
Outcomes	Number who had successful TWOC: A 33/50, B 35/50, C 18/50 Initial catheterisation volume American Urological Association score Post void residual urinary volume (mL) Peak urinary flow rate (mL/sec) Adverse effects
Notes	Second trial phase: successful TWOC patients continued in respective treatment groups and followed up at 1 week, 2 weeks, 1 month and 3 months.

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Method of randomisation not specified: '...randomized into three groups.'
Allocation concealment (selection bias)	Unclear risk	Not specified
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	More detail in tables of analysis needed.
Selective reporting (reporting bias)	Unclear risk	All the outcomes as detailed in the method section of the trial were reported in the result section. Some outcomes which are considered important from patients' perspective were not reported. Without the protocol it was difficult to judge whether or not these outcomes were included in the protocol and not reported in the report.
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Not specified
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not specified
Other bias	Unclear risk	Other aspects of trial design such as baseline comparability, sample size calculation, use of intention-to-treat analysis and financial support were inadequately or not at all specified.

Hua 2003

Methods	Prospective, randomised single centre study
Participants	72 patients (36 tamsulosin, 36 no treatment)
Interventions	A (36): Tamsulosin 0.4 mg once daily for three days B (36): No treatment, TWOC after 3 days (both groups given prophylactic antibiotics)
Outcomes	TWOC success rates: A 22/36, B 10/36
Notes	Full text article in Chinese with English abstract. TWOC success rates stated in English abstract but no other usable data available for any of the specified outcomes.

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	'...were randomly divided into treatment group and control group of 36 patients each.'
Allocation concealment (selection bias)	Unclear risk	Not specified
Incomplete outcome data (attrition bias) All outcomes	Low risk	No incomplete data
Selective reporting (reporting bias)	Unclear risk	All the outcomes as detailed in the method section of the trial were reported in the result section. Some outcomes which are considered important from patients' perspective were not reported. Without the protocol it was difficult to judge whether or not these outcomes were included in the protocol and not reported in the report.
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Not specified
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not specified
Other bias	Unclear risk	Other aspects of trial design such as baseline comparability, sample size calculation and financial support not specified.

Kumar 2013

Methods	Prospective, randomised placebo-controlled single centre study
Participants	60 patients (30 silodosin, 30 placebo). Mean age (SD): • Group A: 64.5 (9.3)

Kumar 2013 (Continued)

- Group B: 65.8 (8.1)

Interventions	A (30): Silodosin 8 mg once daily for 3 days B (30): placebo
Outcomes	Number who had successful TWOC: A 23/30, B 11/30 Factors influencing TWOC failure Effects of silodosin on uroflowmetry and IPSS in patients who had successful TWOC
Notes	Study conducted in tertiary care regional referral centre in Northern India Successful TWOC: <ul style="list-style-type: none"> • 'If the patient voided successfully, a postvoid bladder scan was performed to measure his residual urine volume. If there was less than 150 mL postvoid residual volume after voiding at least 100 mL of urine, he was considered to have a successful TWOC.' Failed TWOC: <ul style="list-style-type: none"> • '...if the patient re-experienced painful AUR or if the PVR urine volume was >150 mL, he was re-catheterised and considered to have a failed TWOC.'

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	'...centrally established computer-assigned randomization list...'
Allocation concealment (selection bias)	Unclear risk	Not specified
Incomplete outcome data (attrition bias) All outcomes	Low risk	No incomplete outcome data
Selective reporting (reporting bias)	Unclear risk	All the outcomes as detailed in the method section of the trial were reported in the result section. Some outcomes which are considered important from patients' perspective were not reported. Without the protocol it was difficult to judge whether or not these outcomes were included in the protocol and not reported in the report.
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Placebo administered was 'similar to silodosin capsule in colour, weight, and shape' Unclear if personnel were blinded.
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not specified
Other bias	Low risk	Study groups were comparable at baseline Power calculation was performed Ethical approval obtained Written informed consent obtained

Kumar 2013 (Continued)

No withdrawals/loss to follow-up

Lucas 2005

Methods	Randomised, double-blind, placebo-controlled, parallel-group, multicentre study
Participants	149 patients (75 tamsulosin, 74 placebo), mean age 69.4 years
Interventions	A (75): Tamsulosin 0.4mg once daily B (74): Placebo TWOC 'after up to 8 doses'
Outcomes	Number who had successful TWOC: A 34/75, B 18/74
Notes	Qmax, PVR volume and spontaneously voided volume analysed but not separately (in groups of 'any two successful criteria')

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	'...randomized, double-blind, placebo-controlled, parallel-group, multicentre study'
Allocation concealment (selection bias)	Unclear risk	Not specified ('...randomly assigned to receive...')
Incomplete outcome data (attrition bias) All outcomes	Low risk	No incomplete data
Selective reporting (reporting bias)	Unclear risk	All the outcomes as detailed in the method section of the trial were reported in the result section. Some outcomes which are considered important from patients' perspective were not reported. Without the protocol it was difficult to judge whether or not these outcomes were included in the protocol and not reported in the report.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Double blinded
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not specified
Other bias	High risk	'This study was sponsored by a grant from Yamanouchi Pharma Ltd.'

McNeill 1999

Methods	Prospective, randomised, placebo-controlled multicentre trial
---------	---

McNeill 1999 (Continued)

Participants	81 patients (40 alfuzosin, 41 placebo), mean age 68.4 years
Interventions	A(40): Alfuzosin SR 5 mg twice daily B (41): Placebo TWOC after 24 hours
Outcomes	Number who had successful TWOC: A 22/40, B 12/41 Factors affecting successful TWOC Incidence of adverse events Incidence of repeat episode of AUR in patients who had successful TWOC Need for surgery in patients who had successful TWOC
Notes	Allocation concealment well explained

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	'...tablets was allocated a study number generated randomly by computer'
Allocation concealment (selection bias)	Low risk	'A sealed copy of the code was held by each participating pharmacy, ...'
Incomplete outcome data (attrition bias) All outcomes	Low risk	No incomplete data.
Selective reporting (reporting bias)	Unclear risk	All the outcomes as detailed in the method section of the trial were reported in the result section. Some outcomes which are considered important from patients' perspective were not reported. Without the protocol it was difficult to judge whether or not these outcomes were included in the protocol and not reported in the report.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Double blinded. 'A central pharmacy...packaged the SR alfuzosin and placebo to appear identical...'
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not specified if assessors were blinded at time of TWOC.
Other bias	High risk	High risk: <ul style="list-style-type: none"> • Baseline comparability: 'The mean age was five years lower in the SR alfuzosin group than in the placebo group (P = 0.049).' • Sample size calculation: 'The initial intention was to recruit 100 patients to each arm of the trial, to detect a 20% difference in outcome with 95% power, but such numbers could not be recruited before the trial medication expired'. • Financial support was obtained from Lorex Synthélabo UK & Ireland. Low risk:

McNeill 1999 (Continued)

- Ethical approval and informed consent obtained.
- Data were analysed on an intention-to-treat basis

McNeill 2005

Methods	Randomised, double-blind, placebo-controlled multicentre trial
Participants	363 patients randomised (A 238, B 122. See notes)
Interventions	A (238): Alfuzosin 10 mg once daily B (122): Placebo Then TWOC after 3 days
Outcomes	Number who had successful TWOC: A 146/236, B 58/121 Factors influencing TWOC success
Notes	Second phase of trial: successful TWOC patients again randomised into alfuzosin versus placebo for 6 months (AUR relapse/ BPH surgery need). Data missing for 3 patients therefore results for primary outcome were reported as sub-totals without these patients (A 236, B 121). Adverse events were however reported as sub-totals including these patients (A 238, B 122)

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	'Patients were randomized...according to a centrally established randomization list.'
Allocation concealment (selection bias)	Unclear risk	Not explained
Incomplete outcome data (attrition bias) All outcomes	High risk	Incomplete data for 3 patients
Selective reporting (reporting bias)	Unclear risk	All the outcomes as detailed in the method section of the trial were reported in the result section. Some outcomes which are considered important from patients' perspective were not reported. Without the protocol it was difficult to judge whether or not these outcomes were included in the protocol and not reported in the report.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Double blinded
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not specified
Other bias	High risk	High risk: <ul style="list-style-type: none"> • Funding obtained from Sanofi-Aventis

McNeill 2005 (Continued)

- Results reported as either intention-to-treat or per-protocol without justification for change.

Low risk:

- Ethical approval and informed consent obtained

Prieto 2008

Methods	Randomised, controlled single centre study
Participants	46 patients (23 doxazosin, 23 no treatment), mean age 74 years
Interventions	A (23): Doxazosin modified release 4 mg once daily B (23): No treatment TWOC on day 32.
Outcomes	TWOC success rates: A 13/22, B 13/24 Maximum urinary flow rate in patients with spontaneous micturition Post-void residual volume in patients with spontaneous micturition
Notes	Second phase trial: successful TWOC patients review at 6, 12 and 24 months for recurrence of AUR

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	High risk	'Two groups were formed.' Patients 'born in even-numbered years' (doxazosin group) versus 'born in odd-numbered years' (no treatment group)
Allocation concealment (selection bias)	High risk	Patients 'born in even-numbered years' (doxazosin group) versus 'born in odd-numbered years' (no treatment group)
Incomplete outcome data (attrition bias) All outcomes	Low risk	No incomplete data
Selective reporting (reporting bias)	Unclear risk	All the outcomes as detailed in the method section of the trial were reported in the result section. Some outcomes which are considered important from patients' perspective were not reported. Without the protocol it was difficult to judge whether or not these outcomes were included in the protocol and not reported in the report.
Blinding of participants and personnel (performance bias) All outcomes	High risk	Blinding is unlikely given the study design.
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not specified
Other bias	High risk	High risk:

Prieto 2008 (Continued)

- Funding obtained from Pfizer.
- Inconsistency in description of intervention for Group B; no medication versus placebo.

Low risk:

- Ethical approval obtained

Shah 2002

Methods	Randomised, double-blind, placebo-controlled single centre study
Participants	62 patients (34 alfuzosin, 28 placebo), mean age 68.6 years
Interventions	A (34): Alfuzosin SR 5 mg twice daily versus B (28): Placebo, TWOC after minimum of three doses or 36 hours after admission
Outcomes	TWOC success rates: A 17/34, B 16/28 Need for further TURP (phase 2)
Notes	Phase 2 of study; all patients with successful TWOC were given Alfuzosin SR 5 mg twice daily and followed up at 1 year and 2 years.

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	'...double blind, placebo controlled study...' 'Patients were randomised to receive ...'
Allocation concealment (selection bias)	Unclear risk	Not specified
Incomplete outcome data (attrition bias) All outcomes	Low risk	No incomplete data
Selective reporting (reporting bias)	Unclear risk	All the outcomes as detailed in the method section of the trial were reported in the result section. Some outcomes which are considered important from patients' perspective were not reported. Without the protocol it was difficult to judge whether or not these outcomes were included in the protocol and not reported in the report.
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Double blinded
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not specified
Other bias	High risk	Funding obtained from Lorex Synthelabo Pharma.

Tiong 2009

Methods	Prospectively, randomised trial single centre study
Participants	67 patients (35 alfuzosin, 32 placebo)
Interventions	A (35): Alfuzosin XL 10 mg once daily B (32): Placebo '...TWOC at least 2h after taking the second dose of trial medication.'
Outcomes	TWOC success rates: A (21/35), B (11/32)
Notes	Both patient groups offered alpha blocker treatment after successful TWOC

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Randomised '...using a centrally established computer-assigned randomization list'.
Allocation concealment (selection bias)	Low risk	'The allocation and administration of treatment were double-blinded'.
Incomplete outcome data (attrition bias) All outcomes	Low risk	No incomplete data
Selective reporting (reporting bias)	Unclear risk	All the outcomes as detailed in the method section of the trial were reported in the result section. Some outcomes which are considered important from patients' perspective were not reported. Without the protocol it was difficult to judge whether or not these outcomes were included in the protocol and not reported in the report.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	'The allocation and administration of treatment were double-blinded'.
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Not specified
Other bias	Low risk	<ul style="list-style-type: none"> Groups comparable at baseline for all characteristics measured (except mean retention urine volume at initial catheterisation; borderline non-significance [P = 0.06]) Ethical approval and informed consent obtained Low withdrawal rate

AUR = acute urinary retention

BPH = benign prostatic hyperplasia

IPSS = International Prostate Symptom Score

PVR = post-void residual

TURP = transurethral resection of the prostate

TWOC = trial without catheter

SD = standard deviation

SR = sustained release
 XL = extended release

Characteristics of excluded studies *[ordered by study ID]*

Study	Reason for exclusion
Joo 2008	Tamsulosin versus no treatment for TWOC in spinal surgery patients electively catheterised perioperatively (not in acute urinary retention prior to surgery).
Kraus 2010	No catheters involved. Urodynamic assessment of daily tadalafil versus placebo on lower urinary tract symptoms.
Lim 1999	No alpha blockers used in study. Study describes outcome of TWOC in 79 untreated patients.
Liu 2009	No catheters involved as patients not in acute urinary retention. Randomised trial of amlodipine with or without terazosin for LUTS.
Lorente 2004	Use of increasing dosage of doxazosin in failed TWOC patients. 40 patients randomly assigned to doxazosin 4 mg once daily (n = 20) or no treatment (n = 20) for seven days before TWOC. Failed TWOC patients either received doxazosin 8mg (treatment group) or 4 mg (control group) once daily before a second TWOC.
Martov 2010	No catheters involved as study assessing tamsulosin for stent-related irritative symptoms.
McNeill 2004	Long-term follow-up study of patient cohort who had successful TWOC following an episode of acute urinary retention (alfuzosin versus placebo).
Taube 1989b	No alpha-blockers used in study. Study describes outcome of TWOC immediately, after 24 and 48 hours in 60 untreated patients (subdivided into three groups).
Wang 2009	No catheters involved as study assessing effect of tamsulosin in patients with indwelling double-J ureteral stents.

LUTS = lower urinary tract symptoms
 TWOC = trial without catheter

Characteristics of studies awaiting assessment *[ordered by study ID]*

[Perepanova 2001](#)

Methods	Prospective, randomised, controlled trial.
Participants	Patients admitted on an emergency basis with AUR due to benign prostatic hyperplasia.
Interventions	Group A: Doxazosin 4 mg Group B: Placebo Catheters removed after 12 hours.
Outcomes	Number with successful TWOC: A 19/30, B 1/6 Need for further surgery: A10/30, B 5/6
Notes	Paper translated from Russian.

Perepanova 2001 (Continued)

Method of randomisation and allocation concealment unclear: 30 patients in Group A, 6 patients in Group B.

Which patient received which surgery unclear.

No statistical analysis was performed on outcomes.

AUR = acute urinary retention

TWOC = trial without catheter

DATA AND ANALYSES
Comparison 1. Alpha blocker versus placebo or control

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Ability to void spontaneously after TWOC without the need for re-catheterisation	9	1094	Risk Ratio (M-H, Fixed, 95% CI)	1.55 [1.36, 1.76]
1.1 Alfuzosin versus control	5	667	Risk Ratio (M-H, Fixed, 95% CI)	1.40 [1.19, 1.64]
1.2 Tamsulosin versus control	3	321	Risk Ratio (M-H, Fixed, 95% CI)	1.97 [1.49, 2.59]
1.3 Doxazosin versus control	1	46	Risk Ratio (M-H, Fixed, 95% CI)	1.09 [0.66, 1.81]
1.4 Silodosin versus control	1	60	Risk Ratio (M-H, Fixed, 95% CI)	2.09 [1.26, 3.48]
2 Incidence of recurrent urinary retention	8	1023	Risk Ratio (M-H, Fixed, 95% CI)	0.69 [0.60, 0.79]
2.1 Alfuzosin versus control	5	667	Risk Ratio (M-H, Fixed, 95% CI)	0.72 [0.60, 0.85]
2.2 Tamsulosin versus control	2	249	Risk Ratio (M-H, Fixed, 95% CI)	0.66 [0.50, 0.87]
2.3 Doxazosin versus control	1	47	Risk Ratio (M-H, Fixed, 95% CI)	0.98 [0.65, 1.48]
2.4 Silodosin versus control	1	60	Risk Ratio (M-H, Fixed, 95% CI)	0.37 [0.18, 0.74]
3 Number with adverse effects due to alpha-blocker treatment	5	1064	Risk Ratio (M-H, Fixed, 95% CI)	1.19 [0.75, 1.89]
3.1 Alfuzosin versus control	3	868	Risk Ratio (M-H, Fixed, 95% CI)	0.91 [0.53, 1.54]

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
3.2 Tamsulosin versus control	1	149	Risk Ratio (M-H, Fixed, 95% CI)	2.71 [0.90, 8.14]
3.3 Doxazosin versus control	1	47	Risk Ratio (M-H, Fixed, 95% CI)	3.13 [0.13, 73.01]
4 Number with serious adverse effects due to alpha-blocker treatment	1		Risk Ratio (M-H, Fixed, 95% CI)	Totals not selected
4.1 Alfuzosin versus control	1		Risk Ratio (M-H, Fixed, 95% CI)	0.0 [0.0, 0.0]
5 Number of drop-outs due to adverse effects of alpha blockers treatment	5	705	Risk Ratio (M-H, Fixed, 95% CI)	3.94 [1.28, 12.12]
5.1 Alfuzosin versus control	3	509	Risk Ratio (M-H, Fixed, 95% CI)	2.83 [0.62, 12.93]
5.2 Tamsulosin versus control	1	149	Risk Ratio (M-H, Fixed, 95% CI)	6.91 [0.87, 54.76]
5.3 Doxazosin versus control	1	47	Risk Ratio (M-H, Fixed, 95% CI)	3.13 [0.13, 73.01]

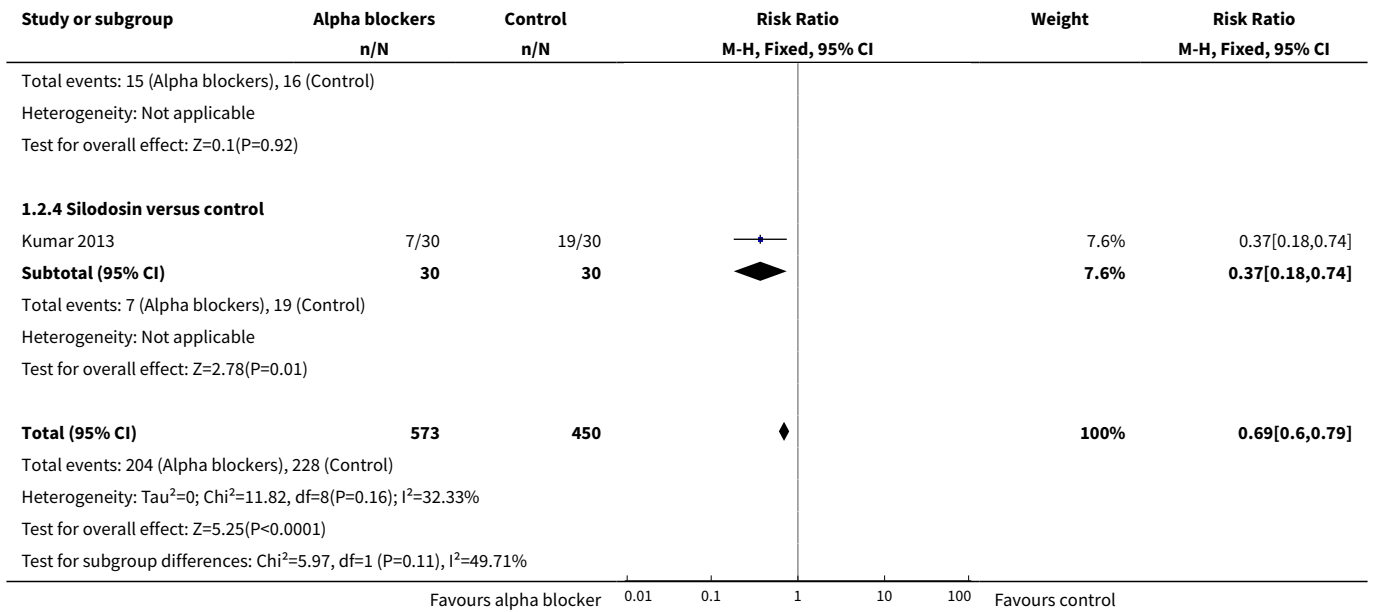

Analysis 1.1. Comparison 1 Alpha blocker versus placebo or control, Outcome 1 Ability to void spontaneously after TWOC without the need for re-catheterisation.

Analysis 1.2. Comparison 1 Alpha blocker versus placebo or control, Outcome 2 Incidence of recurrent urinary retention.

Analysis 1.3. Comparison 1 Alpha blocker versus placebo or control, Outcome 3 Number with adverse effects due to alpha-blocker treatment.

Analysis 1.4. Comparison 1 Alpha blocker versus placebo or control, Outcome 4 Number with serious adverse effects due to alpha-blocker treatment.

Analysis 1.5. Comparison 1 Alpha blocker versus placebo or control, Outcome 5 Number of drop-outs due to adverse effects of alpha blockers treatment.

APPENDICES

Appendix 1. Details of the additional searches performed for the current version of the review

The following additional searches were performed for this review:

CENTRAL (on OVID SP) (May 2013) was last searched on 5 June 2013 using the following search terms:

1. exp Adrenergic alpha-Antagonists/
2. catheterization/ or urinary catheterization/
3. 1 and 2
4. Urinary Retention/
5. 1 and 4
6. twoc.tw.
7. trial without catheter.tw.
8. trial off catheter.tw.
9. 3 or 5 or 6 or 7 or 8

EMBASE Classic + EMBASE 1947 to 2013 Wk 22, **MEDLINE** 1946 to May Week 4 2013 and **MEDLINE in Process** (covering to 3 June 2013) (all on OVID SP) were last searched on 4 June 2013 using the following search terms:

1. exp Adrenergic alpha-Antagonists/
2. catheterization/ or urinary catheterization/
3. 1 and 2
4. twoc.tw.
5. trial without catheter.tw.
6. trial off catheter.tw.
7. 3 or 4 or 5 or 6
8. controlled clinical trial.pt.
9. randomized controlled trial.pt.
10. randomized controlled trials/
11. random allocation/

Appendix 2. Details of the searches performed by original review authors for the original version of the review (Zeif 2009)

The review authors performed electronic searches in the following databases for the original version of the review (Zeif 2009): CENTRAL, MEDLINE and EMBASE (last search 13 February 2008). The search terms used in all three databases were: trial without catheter AND urinary retention AND alpha blocker. A further search of MEDLINE (January 2005 to January Week 4 2009) was performed (11 February 2009) using the search term: trial without catheter.mp.

FEEDBACK

The role of alpha blockers prior to removal of urethral catheter for acute urinary retention in men, 13 July 2014

Summary

Dear Editor,

I would like to make the following comments related to the main conclusion of this article, namely: "There was some evidence to suggest that alpha blockers increase the success rates of trial without catheter, and the incidence of adverse effects was low."

- Tamsulosin is associated with severe hypotension (Bird 2013, Ramirez 2013)
- Over three quarters of registered human studies with this drug are unpublished (Ramirez 2014)

Jorge H Ramírez

Reply

Dear Professor Ramirez,

Thank you for your feedback. In this systematic review, the number of people with adverse effects due to alpha blockers was reported in Analysis 1.3. The results were not statistically significant (Risk Ratio 1.19; 95% Confidence interval (CI) 0.75 to 1.89), and had a wide confidence interval. Forty-one out of 649 in the treatment group and 22/415 in the control group reported adverse effects. The number of people with serious adverse effects due to alpha blocker treatment was reported in Analysis 1.4. These results were also not statistically significant (Risk Ratio 0.77; 95% CI 0.13 to 4.54), and only 3/238 in the treatment group reported serious adverse effects.

We also highlight within the abstract and plain language summary that alpha blockers are associated with adverse effects, specifically:

- "Of the trials mentioning adverse effects (for example, postural hypotension, dizziness), there was not enough information to detect statistically significant differences between the groups"– Abstract.
- "Side effects caused by alpha blockers were few and comparable to placebo or no treatment, though this evidence was limited. They included retrograde ejaculation, dizziness, low blood pressure, fainting, sleepiness, feeling unwell and headache." – Plain Language Summary

In your study we noticed that the incidence of hypotension for tamsulosin was 42.4 events per 10,000 person years. We think that this shows that the incidence of hypotension is indeed low. Out of 383,567 participants, 2562 admissions to hospital for severe hypotension were identified in your study (Bird 2013). Moreover, in our review the use of alpha blockers was short term, covering only the period prior to removal urethral catheter. However, we note the large amount of unpublished evidence regarding tamsulosin (and probably other alpha blockers) and have added a caveat in the review to this effect (Ramirez 2014).

“However, the data in this review are limited due to the large amount of unpublished data that was not available to us” (Ramirez 2014)

With kind regards,

Muhammad Imran Omar

WHAT'S NEW

Date	Event	Description
3 November 2014	Feedback has been incorporated	Response from the review authors Feedback 1

HISTORY

Protocol first published: Issue 3, 2007

Review first published: Issue 4, 2009

Date	Event	Description
5 June 2014	New citation required but conclusions have not changed	Added five new trials (Agrawal 2009; Hua 2003; Kumar 2013; Prieto 2008; Tiong 2009) in this update. Risk of bias was re-assessed incorporating additional domains as per current recommendation. Quality of evidence assessed by using the GRADE approach.
5 June 2014	New search has been performed	Added five new trials (Agrawal 2009; Hua 2003; Kumar 2013; Prieto 2008; Tiong 2009) in this update. Risk of bias was re-assessed incorporating additional domains as per current recommendation. Quality of evidence assessed by using the GRADE approach.
16 September 2008	Amended	Converted to new review format.

CONTRIBUTIONS OF AUTHORS

For the 2014 update, two review authors (EF, MO) independently assessed the identified trials, extracted data and performed 'Risk of bias' assessment. EF and MO assessed the quality of evidence of the critical outcomes. All review authors contributed to the analysis of data. EF took the lead in modifying the manuscript and all review authors contributed to writing the manuscript.

Hans-Joerg Zeif conceived, drafted and wrote the original review. Kesavapillai Subramonian critically revised and approved the review. Both review authors independently examined all the citations and abstracts derived from the search strategy and extracted, cross-checked and processed data independently as described in the Cochrane Collaboration Handbook.

DECLARATIONS OF INTEREST

The review authors have no conflict of interest to declare.
