## Abstract

SNHG3, a long noncoding RNA (lncRNA), has been linked to poor outcomes in patients with liver hepatocellular carcinoma (LIHC). In this study, we found that SNHG3 was overexpressed in LIHC and associated with poor outcomes in patients with LIHC. Functional assays, including colony formation, spheroid formation, and in vivo assays showed that SNHG3 promoted stemness of cancer stem cells (CSC) and tumor growth in vivo by interacting with microRNA-502-3p (miR-502-3p). miR-502-3p inhibitor repressed the tumor-suppressing effects of SNHG3 depletion. Finally, by RNA pull-down, dual-luciferase reporter assay, m6A methylation level detection, and m6A-IP-qPCR assays, we found that miR-502-3p targeted YTHDF3 to regulate the translation of integrin alpha-6 (ITGA6) and targeted HBXIP to inhibit the m6A modification of ITGA6 through methyltransferase-like 3 (METTL3). Our study revealed that SNHG3 controls the YTHDF3/ITGA6 and HBXIP/METTL3/ITGA6 pathways by repressing miR-502-3p expression to sustain the self-renewal properties of CSC in LIHC.

cancer stem cells, ITGA6, liver hepatocellular carcinoma, long noncoding RNA SNHG3, microRNA-502-3p

## 1 | INTRODUCTION

With a 5-year survival of 18%, liver cancer is the second most lethal tumor after pancreatic cancer.<sup>1</sup> For patients with early-stage liver hepatocellular carcinoma (LIHC) with no history of cirrhosis or portal

hypertension, resection is recommended, but it is associated with a recurrence rate of approximately 60%–70% at 5 years.<sup>2</sup> The majority of patients with the most frequent subtype of LIHC are diagnosed at advanced stages, at which treatment options are limited to systemic therapy.<sup>3</sup> Cancer stem cells (CSC), a small population of tumor

**Abbreviations:** CSC, cancer stem cells; DMEM, Dulbecco's modified Eagle's medium; FBS, fetal bovine serum; FISH, fluorescence in situ hybridization; HBXIP, hepatitis B virus X-interacting protein; ITGA6, integrin alpha-6; LIHC, liver hepatocellular carcinoma; METTL3, methyltransferase-like 3; RIP, RNA immunoprecipitation; SNHG3, small nucleolar RNA host gene 3; YTHDF3, YTH domain-containing family protein 3.

cells, have been revealed to hold highly tumorigenic, metastatic, and chemotherapy- and radiation-resistant properties, thus resulting in relapse after therapy.<sup>4</sup> Therefore, studying the molecular crosstalk underlying the maintenance of CSC in LIHC is of great value in improving patient prognosis.

The significance of long noncoding RNAs (lncRNAs) in the initiation and progression of LIHC has been appreciated because they govern the proliferation, apoptosis, vessel formation, and invasive ability of cancer cells by binding to DNA, RNA, or proteins.<sup>5</sup> Mechanistically, the competing endogenous RNA (ceRNA) model describes lncRNAs as sponges for microRNAs (miRNAs) to indirectly modulate the targets of miRNAs.<sup>6</sup> SNHG3s are a family of lncRNAs that are overexpressed in many malignancies, including respiratory and digestive tumors.<sup>7</sup> SNHG3 primarily competes as a ceRNA that targets tumor suppressor miRNAs, thereby regulating biological processes in tumors.<sup>8</sup> Moreover, SNHG3 has been identified as one of the 11 CSC-related lncRNAs with prognostic value in LIHC.<sup>9</sup> However, its functional role in regulating CSC in LIHC remains unclear. By intersection of differentially expressed miRNAs in the GSE108724 and GSE166348 datasets and possible targets of SNHG3 in the Starbase website (<https://starbase.sysu.edu.cn/index.php>), we obtained four candidates: hsa-miR-500a-3p, hsa-miR-502-3p, hsa-miR-151a-3p, and hsa-miR-196b-5p. Only miR-502-3p has not been reported to be related to the stemness of CSC.<sup>10-12</sup> Therefore, we selected miR-502-3p for subsequent assays.

We previously reported that miR-448 targets YTHDF3, thus controlling the expression of ITGA6,<sup>13</sup> a factor generally used to identify CSC populations and sustain the self-renewal of CSC.<sup>14</sup> In contrast, HBXIP was shown to potentiate the malignant biological behaviors of LIHC cells via N6-methyladenosine (m6A) modification of hypoxia-inducible factor-1 $\alpha$  in a METTL3-dependent manner.<sup>15</sup> Intriguingly, METTL3 catalyzes the m6A modification of ITGA6, thereby encouraging the translation of ITGA6 mRNA.<sup>16</sup> These data led us to hypothesize that HBXIP and YTHDF3 are the putative targets of miR-502-3p. The motivation and innovation of this study was to decode the interaction between SNHG3 and miR-502-3p in two possible pathways, the YTHDF3/ITGA6 axis and the HBXIP/METTL3/ITGA6 axis in LIHC, thereby providing an understanding of the role of SNHG3 in LIHC.

## 2 | MATERIALS AND METHODS

### 2.1 | Tumor tissue collection

Cancerous and adjacent tissues resected from 86 patients who had been diagnosed with LIHC at the Central South University Xiangya School of Medicine Affiliated Haikou Hospital between March 2019 and March 2021 were collected. None of the patients had received chemotherapy or drugs before surgery. The patients were followed up every 2 months after surgery, with a total follow-up period of 12 months. The study was approved by

the Ethics Committee of Central South University Xiangya School of Medicine Affiliated Haikou Hospital, in compliance with the Declaration of Helsinki. Informed consent was obtained from all patients.

### 2.2 | Cell culture and lentiviral infection

Huh7 and PLC/PRF/5 cells were cultured in DMEM/F12 containing 10% FBS, 100  $\mu$ g/mL penicillin, and 100 U/mL streptomycin. For CSC isolation, Huh7 and PLC/PRF/5 cells were grown in serum-free DMEM/F12 medium (Thermo Fisher Scientific Inc.) with penicillin-streptomycin, B27 supplement, 20 ng/mL EGF, 20 ng/mL bFGF, and N2 supplement for 2 weeks. The medium was renewed every 3 days. The cells forming spheres in the supernatant were made into single-cell suspensions (termed PLC/PRF/5/CSC or Huh7/CSC). The CSC markers, CD13 and CD133, were subsequently identified using flow cytometry. PLC/PRF/5/CSC or Huh7/CSC cells were cultured in DMEM/F12 plus penicillin-streptomycin, B27 supplement, 20 ng/mL EGF, 20 ng/mL bFGF, and N2 supplement at 37°C with 5% CO<sub>2</sub>.

The lentiviral vectors were designed and constructed by GenePharma. Huh7/CSC and PLC/PRF/5/CSC cells were infected with different lentiviral vectors for 72 h. Positive cells were screened using puromycin, and the effect of infection was verified by RT-qPCR or Western blot. Detailed methods of malignant phenotype measurements and binding relation assessments can be found in Appendix S1.

### 2.3 | RT-qPCR

The TRIzol kit was used for total RNA extraction, and a PrimeScript™ RT reagent kit (RR037Q, Takara Biotechnology Ltd.) was used for reverse transcription. TB Green® Premix Ex Taq™ II (RR820Q; Takara) was used for qPCR. Quantitative analysis of miRNA was performed using the Mir-X miRNA qRT-PCR TB Green Kit (638314, Takara). mRNA or miRNA expression was normalized to  $\beta$ -actin or U6 and calculated using the 2<sup>- $\Delta\Delta$ Ct</sup> method. Primers used are listed in Table 1.

### 2.4 | Western blot

Cells or tissues were lysed in RIPA lysis buffer containing 1% protease inhibitor with 1% phosphatase inhibitor. The proteins were separated by SDS-PAGE and transferred to PVDF membranes. The membranes were sequentially sealed with goat serum and incubated with primary antibodies (Appendix S1) overnight at 4°C and with HRP-conjugated goat anti-rabbit secondary antibody (1:2000, ab6721, Abcam) for 120 min at room temperature. An ECL kit was used for protein development, and band intensity was analyzed using ImageJ software.

## 2.5 | Animal studies

The experimental protocol was authorized by the ethics committee of the Central South University Xiangya School of Medicine Affiliated Haikou Hospital and conformed to the Guide for the Care and Use of Laboratory Animals. Five-week-old male BALB/c nude mice ( $n=120$ , Vital River) were maintained under specific pathogen-free (SPF) conditions.

For tumor growth assessment,  $10^4$  Huh7/CSC infected with different lentiviral vectors were mixed with Matrigel at a 1:1 ratio, and the mixture was injected subcutaneously into nude mice ( $n=6$ ). Tumor volume was assessed every other week during the experiment using the following formula: (long diameter  $\times$  short diameter<sup>2</sup>)/2. At week 5 after injection, the nude mice were euthanized using 150 mg/kg sodium pentobarbital. The tumor tissues were weighed, and 4- $\mu$ m paraffin sections were prepared from the tumor tissues after embedding in paraffin.

For mouse survival assessment, a mixture of  $10^5$  infected Huh7/CSC cells with Matrigel was administered to the liver of nude mice. The mice were monitored daily, and the time of death was recorded. The mortality rate of the mice was analyzed after the death of the last mouse in each group ( $n=6$ ).

## 2.6 | Immunohistochemistry

Paraffin-embedded sections of subcutaneous tumor tissues were de-waxed, rehydrated, and heated for antigen retrieval. Goat serum sealing was performed to avoid nonspecific binding. The sections were probed with the antibody against Ki67 (1:200, ab15580, Abcam) overnight at 4°C and with goat anti-rabbit secondary antibody (1:1000, ab6721, Abcam) for 0.5 h at room temperature. The sections were stained with DAB, and positivity was observed under a light microscope.

## 2.7 | Statistical analyses

All data were analyzed using GraphPad Prism 8.0 (GraphPad) and are indicated as mean  $\pm$  SD. Comparisons between the two groups were

analyzed using paired or unpaired t-tests. The data among multiple groups were analyzed using one-way or two-way ANOVA and Tukey's post-hoc test. Kaplan-Meier analysis was used to generate survival curves, and Pearson's correlation coefficient was used to evaluate the correlation of indicators. Statistical significance was set at  $p < 0.05$ .

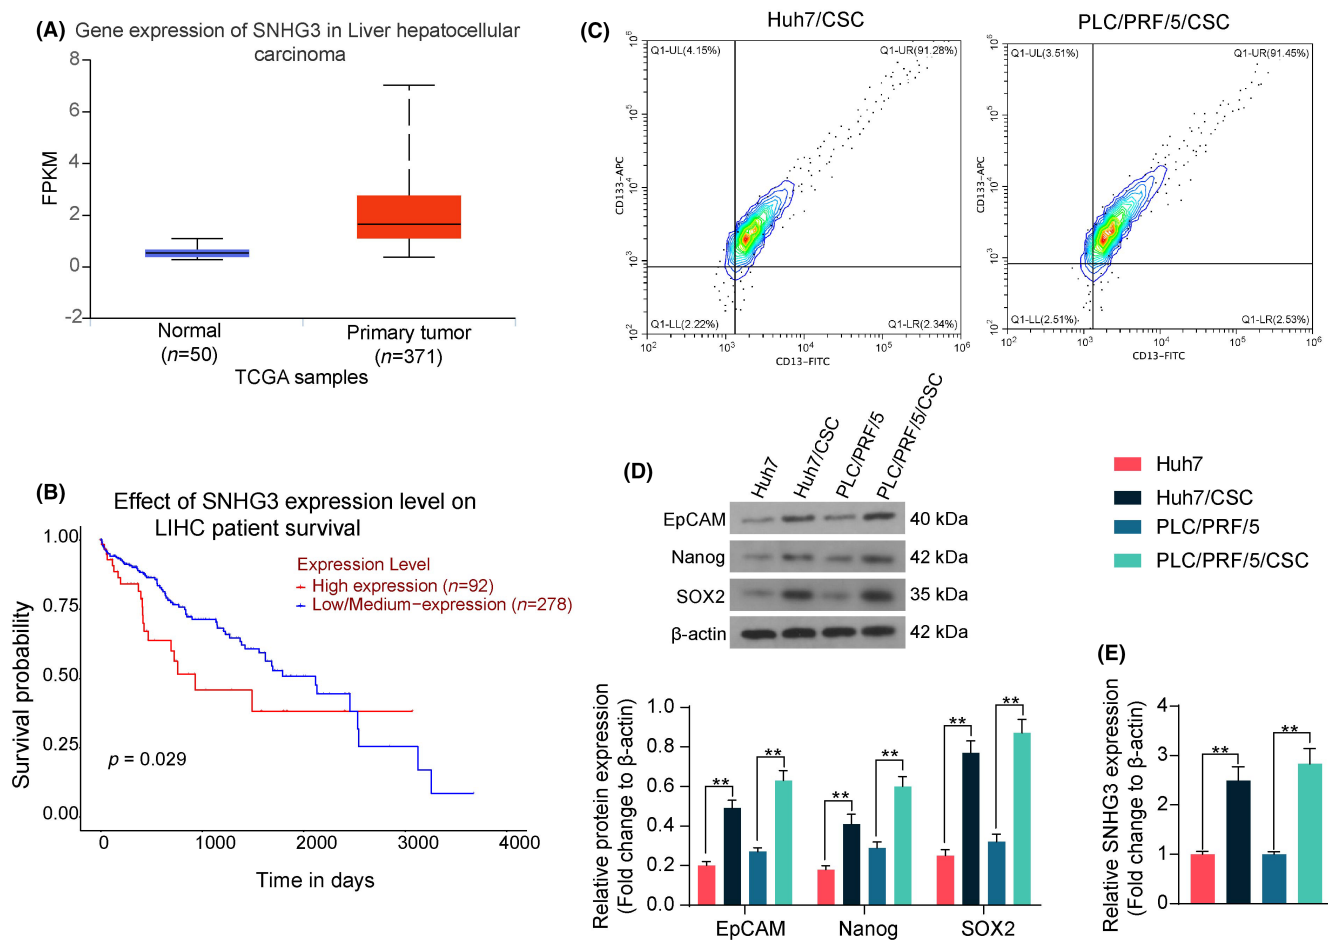

## 3 | RESULTS AND DISCUSSION

The oncogenic role of SNHG3 has been indicated in bladder cancer,<sup>17</sup> non-small cell lung cancer,<sup>18</sup> oral squamous cell carcinoma,<sup>19</sup> and gastric cancer.<sup>20</sup> More importantly, SNHG3 has been reported to induce epithelial-mesenchymal transition and sorafenib resistance by mediating the miR-128/CD151 pathway in LIHC.<sup>21</sup> However, there are no clues regarding the sustained effects of SNHG3 on CSC in LIHC.

### 3.1 | SNHG3 is overexpressed in LIHC and linked to the stemness of LIHC cells

In the UALCAN database (<http://ualcan.path.uab.edu/index.html>), SNHG3 was found to be overexpressed in LIHC (Figure 1A), which was associated with poor patient prognosis (Figure 1B). RT-qPCR and FISH in tumors and adjacent tissues from our cohort showed overexpression of SNHG3 in tumor tissues (Figure S1A,B). Patients were categorized into high- and low-SNHG3-expression groups based on median SNHG3 expression. Survival was worse in patients with high SNHG3 expression levels (Figure S1C). CSCs are regulated by the expression of several stemness-associated genes, such as SOX2 and Nanog, and CSCs within LIHC are mostly marked by various surface markers, including EpCAM.<sup>22</sup> Intriguingly, the expression of SNHG3 was positively correlated with EpCAM, Nanog, and SOX2 expression (Figure S1D).

We isolated Huh7/CSC and PLC/PRF/5/CSC, and flow cytometry analysis of the CSC markers CD13 and CD133 confirmed the successful isolation of Huh7/CSC and PLC/PRF/5/CSC (Figure 1C). A much higher expression of stemness-related genes was observed

**FIGURE 1** Overexpression of SNHG3 in liver hepatocellular carcinoma (LIHC) relates to the stemness of cancer stem cells (CSC). (A) UALCAN database analysis of SNHG3 expression in LIHC. (B) UALCAN database analysis of SNHG3 expression in LIHC with patient survival. (C) Detection of stem cell markers in CSC populations by flow cytometry. (D) EpCAM, Nanog, and SOX2 protein expression in Huh7, PLC/PRF/5, and CSC populations using Western blot. (E) SNHG3 expression in Huh7, PLC/PRF/5, and CSC populations using RT-qPCR. in Huh7/CSC and PLC/PRF/5/CSC cell lines (Figure 1D), along with elevated expression of SNHG3 (Figure 1E).

### 3.2 | Depletion of SNHG3 hinders self-renewal properties of CSC and curbs tumor growth

SNHG3 expression was reduced in Huh7/CSC and PLC/PRF/5/CSC using the three shRNAs. The shRNA with the highest efficiency was selected using RT-qPCR and FISH for subsequent assays (Figure 2A,B). Knockdown of SNHG3 decreased the expression of stemness-associated genes in Huh7/CSC and PLC/PRF/5/CSC (Figure 2C). Depletion of SNHG3 repressed cell viability and colony formation, but its overexpression overturned this effect in osteosarcoma.<sup>23</sup> Furthermore, knockdown of SNHG3 restrained the tumor growth of prostate cancer cells and elevated methionine dependence in vivo.<sup>24</sup> Soft agar colony formation and sphere-forming assays revealed a significant decrease in colony formation and sphere-forming abilities of Huh7/CSC and PLC/PRF/5/CSC

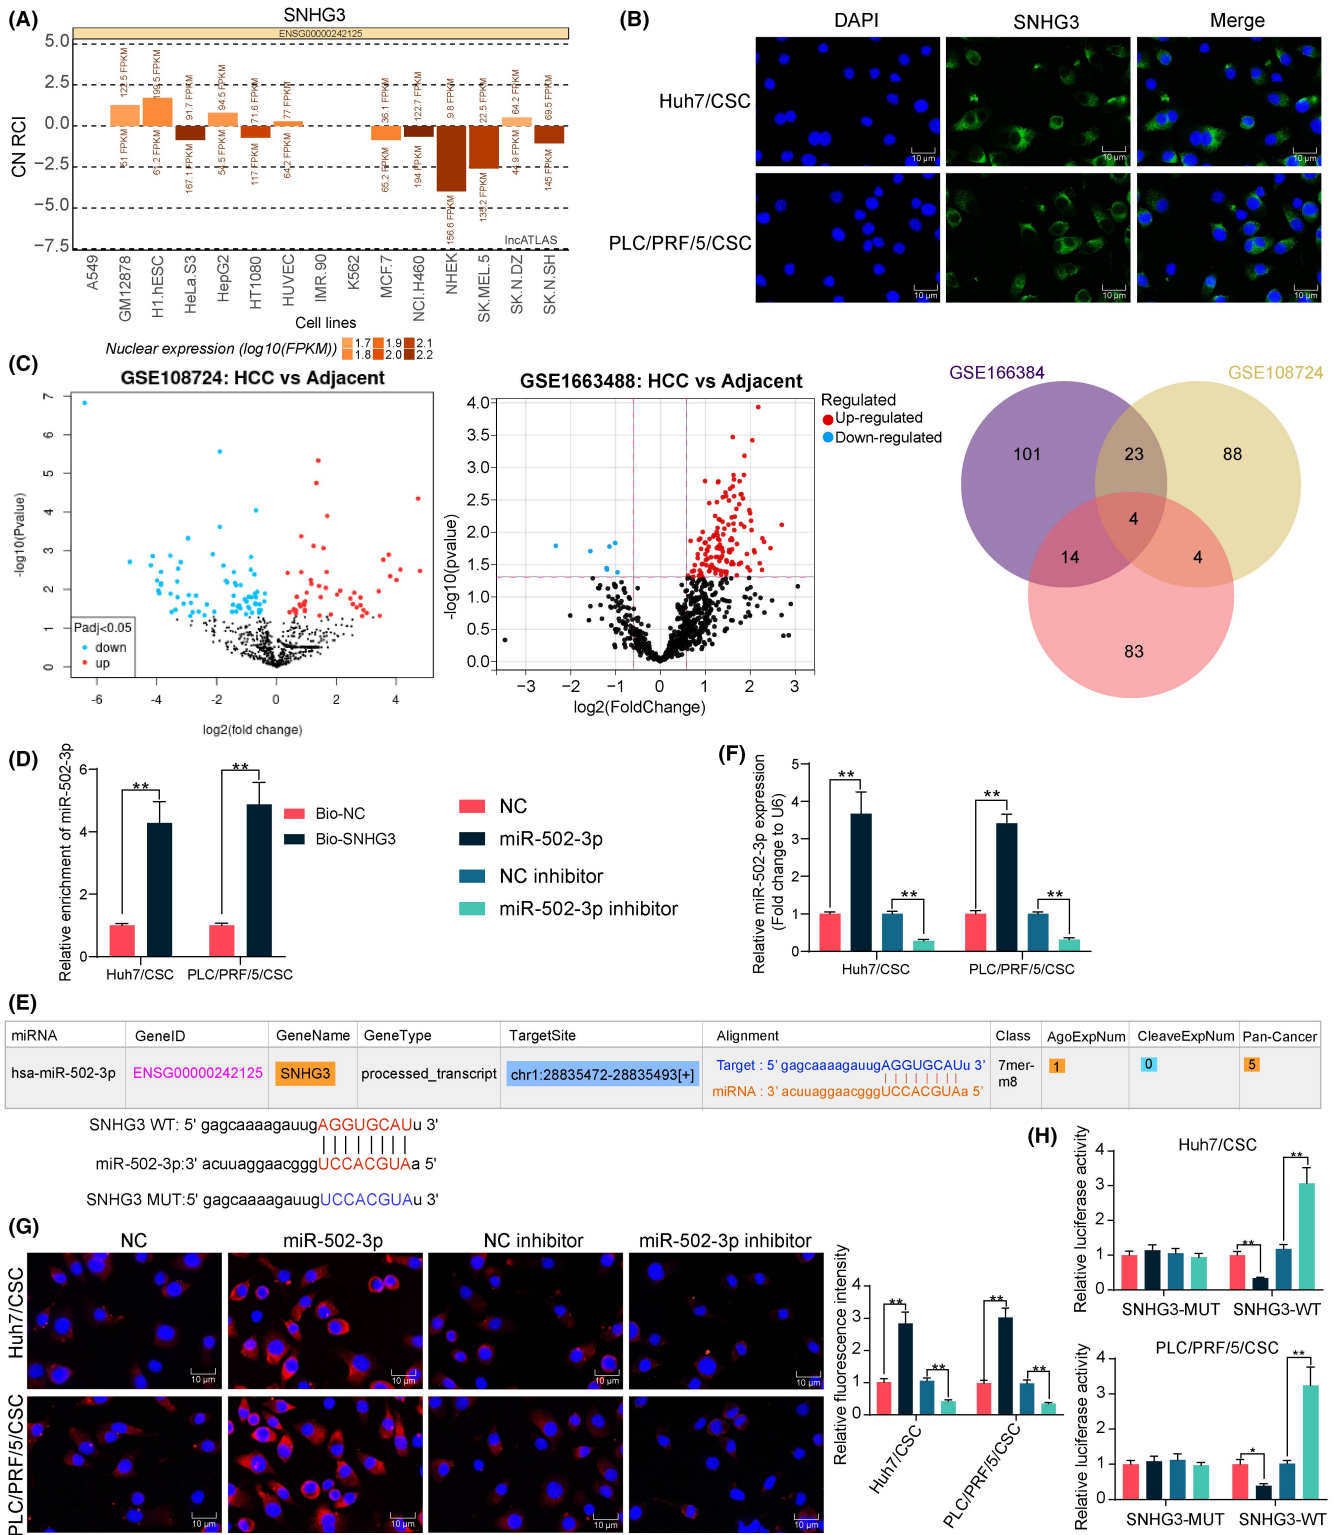

cells in response to SNHG3 inhibition (Figure 2D,E). Cell migration and invasion were reduced after SNHG3 depletion (Figure 2F,G). Loss of SNHG3 inhibited subcutaneous tumor volume and tumor weight (Figure 2H), with a significant decline in Ki67 expression in tumor tissues (Figure 2I). The survival rate of mice with orthotopic implantation of Huh7/CSC with sh-SNHG3 was enhanced compared with that of the control group (Figure 2J).

### 3.3 | SNHG3 interacts with miR-502-3p

SNHG3 was predicted in the LncAtlas database (<https://lncatlas.crg.eu/>) to be predominantly localized in the cytoplasm of LIHC cells (Figure 3A), which was further confirmed in Huh7/CSC and PLC/PRF/5/CSC cells using FISH (Figure 3B). We then predicted miRNAs sharing interaction sites with SNHG3 in the Starbase database, followed by the intersection with the differentially expressed miRNAs in LIHC-related GSE108724 and GSE166348 (Figure 3C). Four differentially expressed miRNAs,

**FIGURE 2** SNHG3 depletion reduces the stemness of cancer stem cells (CSC) and tumor growth in liver hepatocellular carcinoma (LIHC). SNHG3 expression after knockdown of SNHG3 in CSC populations using RT-qPCR (A) and FISH (B). (C) EpCAM, Nanog, and SOX2 protein expression in CSC populations using Western blot. The colony formation (D), sphere-forming ability (E), migration (F), and invasion (G) of CSC populations were assessed. (H) The tumor growth of mice injected with CSC populations. Data are presented as mean  $\pm$  SD ( $n = 6$ ) and analyzed using unpaired  $t$ -test or two-way ANOVA. \*\* $p < 0.01$ .

**FIGURE 3** SNHG3 competitively binds to miR-502-3p. (A) The localization of SNHG3 predicted in the LncAtlas database. (B) FISH detection of SNHG3 localization in cancer stem cell (CSC) populations. (C) The intersection of differentially expressed genes and miRNA targets of SNHG3 in the Starbase database. (D) The binding relationship between SNHG3 and miR-502-3p was analyzed using RNA pull-down. (E) Analysis of SNHG3 binding sites to miR-502-3p and binding site mutation sequence design by the Starbase database. miR-502-3p expression after miR-502-3p or inhibitor treatment in CSC populations by RT-qPCR (F) and FISH (G). (H) The luciferase activity in CSC populations was analyzed using a dual-luciferase reporter assay. Data are presented as mean  $\pm$  SD and analyzed using two-way ANOVA. \*\* $p < 0.05$ , \*\*\* $p < 0.01$ .

hsa-miR-500a-3p, hsa-miR-502-3p, hsa-miR-151a-3p, and hsa-miR-196b-5p, were screened. miR-502-3p was also identified to interact with circular RNA ribosomal protein L15 in gastric cancer<sup>25</sup> and lncRNA PRKAG2-AS1 in LIHC.<sup>26</sup> Therefore, miR-502-3p was selected as the miRNA of interest.

RT-qPCR and FISH showed that miR-502-3p expression was reduced in the collected LIHC tissues (Figure S2A,B). RNA pull-down experiments confirmed the binding relationship between SNHG3 and miR-502-3p (Figure 3D). Next, we obtained the binding sites of SNHG3 for miR-502-3p from the Starbase database and mutated the binding site (Figure 3E). Huh7/CSC and PLC/PRF/5/CSC were transfected with miR-502-3p or inhibitor, followed by efficiency validation using RT-qPCR and FISH (Figure 3F,G). The relative luciferase activity of SNHG3-WT was significantly reduced or augmented upon transfection with miR-502-3p or inhibitor, respectively (Figure 3H).

### 3.4 | miR-502-3p inhibitor compromises the tumor-suppressive effects of sh-SNHG3

As expected, miR-502-3p expression was lower in Huh7/CSC and PLC/PRF/5/CSC cells than in Huh7 and PLC/PRF/5 cells (Figure 4A,B). miR-502-3p inhibitor was used to infect Huh7/CSC and PLC/PRF/5/CSC with SNHG3 knockdown, and miR-502-3p was downregulated after infection in the cells (Figure 4C,D). Intervention with miR-502-3p inhibitor increased the expression of EpCAM, Nanog, and SOX2 in cells (Figure 4E), and a significant promotion in the colony formation and sphere-forming ability of Huh7/CSC and PLC/PRF/5/CSC (Figure 4F,G) and a significant elevation in the migration and invasion of cells were observed (Figure 4H,I). Inhibition of miR-502-3p accelerated subcutaneous tumor growth, as evidenced by an increase in tumor volume and weight (Figure 4J) and an increase in the number of Ki67-positive cells in the tumor tissue (Figure 4K). miR-502-3p inhibitor caused shorter surviving days in mice (Figure 4L).

### 3.5 | miR-502-3p targets YTHDF3 to suppress ITGA6 expression

m6A is a ubiquitous post-transcriptional modification of RNA, and abnormal m6A modification is tightly linked to LIHC progression.<sup>27,28</sup> The m6A-related regulators, including writers (METTL3, METTL14, METTL5, and METTL16), erasers (ALKBH5, ALKBH3, and FTO), and readers (YTHDF1, YTHDF2, YTHDF3, YTHDC1, and YTHDC2) cooperatively maintain the dynamic and reversible balance of m6A methylation.<sup>29</sup> As YTHDF3 has been a research target and ITGA6 is a target of YTHDF3 in our previous study regarding LIHC,<sup>13</sup> we wondered whether miR-502-3p targeted YTHDF3 to mediate the expression of ITGA6 in LIHC. In the StarBase database, miR-502-3p was found to bind to YTHDF3 (Figure 5A), so we speculated that miR-502-3p regulates ITGA6 expression through YTHDF3. YTHDF3

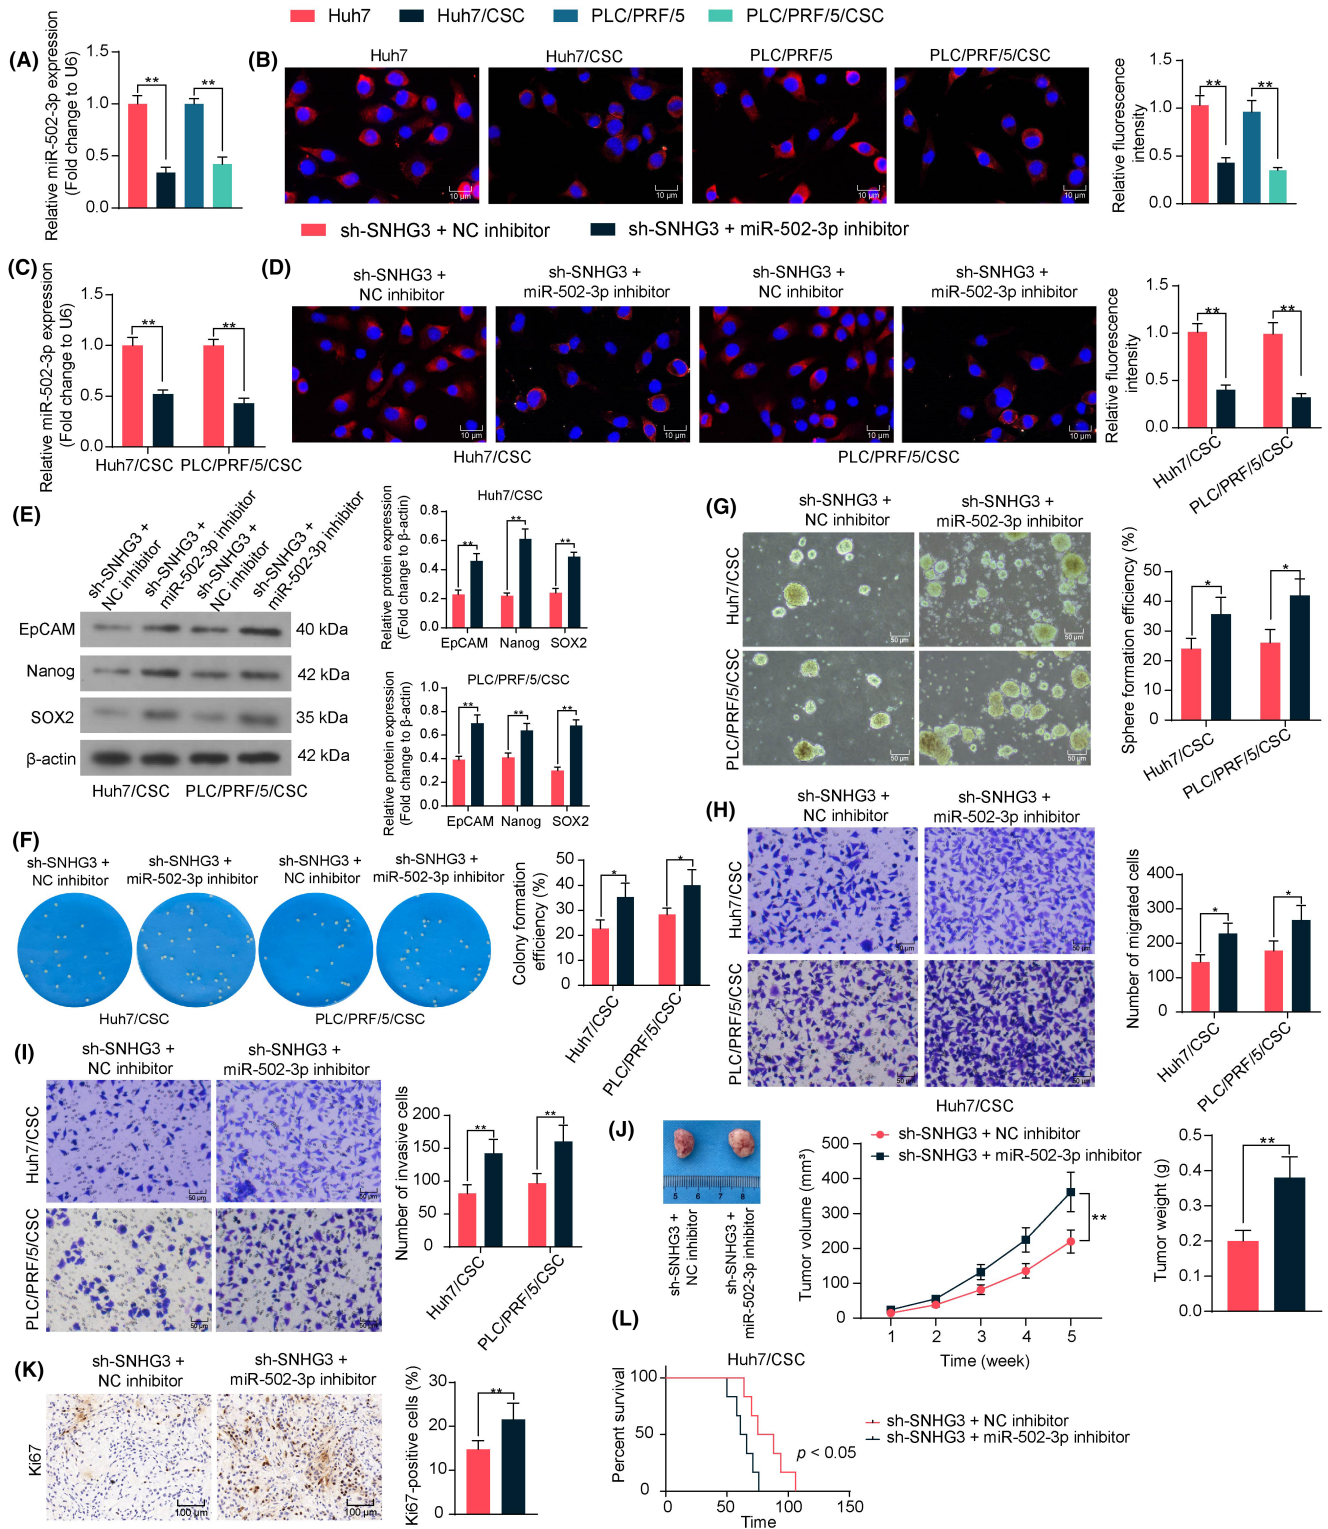

expression was elevated in LIHC according to the Starbase database (Figure 5B).

YTHDF3 expression was elevated in clinical LIHC tissues, and miR-502-3p was negatively correlated with YTHDF3 expression (Figure S2C). Western blot analysis also revealed significantly elevated YTHDF3 expression in LIHC tissues (Figure S2D). YTHDF3 mRNA and protein expression was detected in Huh7/CSC and PLC/PRF/5/CSC infected with sh-SNHG3 alone or in combination with miR-502-3p inhibitor. SNHG3 inhibition led to a decrease in YTHDF3 expression, and the miR-502-3p inhibitor partially restored YTHDF3 expression in the presence of sh-SNHG3 (Figure 5C,D). The binding relationship between miR-502-3p and YTHDF3 was confirmed using an RNA pull-down assay (Figure 5E). We mutated the binding sites of miR-502-3p and YTHDF3 and observed that the luciferase activity of YTHDF3-WT was decreased upon transfection with miR-502-3p and increased following transfection with miR-502-3p inhibitor (Figure 5F).

StarBase analysis showed elevated ITGA6 expression in LIHC (Figure 5G). Consistently, our enrolled patients with LIHC showed an upregulation of ITGA6, which was positively correlated with YTHDF3 expression (Figure S2E). RIP experiments confirmed the binding of YTHDF3 to the ITGA6 mRNA (Figure 5H). Huh7/CSC and PLC/PRF/5/CSC cells with a YTHDF3 knockdown were generated. After verifying transfection efficiency, we observed that YTHDF3 downregulation contributed to a decline in the protein expression of YTHDF3 and ITGA6 (Figure 5I,J). SNHG3 inhibition led to a remarkable decline in the protein expression of ITGA6, whereas the miR-502-3p inhibitor significantly augmented ITGA6 protein expression in the cells (Figure 5K).

### 3.6 | YTHDF3 promotes the translation of ITGA6 in LIHC

We overexpressed ITGA6 in Huh7/CSC and PLC/PRF/5/CSC based on the knockdown of YTHDF3 or knockdown of SNHG3, in which ITGA6 expression was significantly restored (Figure 6A). Knockdown of YTHDF3 decreased stemness-related gene expression, whereas overexpression of ITGA6 contributed to the upregulation of tumor stemness-related genes (Figure 6B). The colony-forming ability and sphere-forming ability of Huh7/CSC and PLC/PRF/5/CSC were reduced following knockdown of YTHDF3, and the self-renewal ability of Huh7/CSC and PLC/PRF/5/CSC was enhanced after overexpression of ITGA6 in addition to YTHDF3 or SNHG3 knockdown (Figure 6C,D). Transwell assays confirmed the repressive effect of YTHDF3 and SNHG3 knockdown on cell migration and invasion was reversed by ITGA6 (Figure 6E,F). Depletion of YTHDF3 inhibited subcutaneous tumor growth, whereas overexpression of ITGA6 promoted tumor growth (Figure 6G), which occurred concomitantly with the elevated KI67 expression (Figure 6H). Knockdown of YTHDF3 prolonged the survival of tumor-bearing mice, whereas ITGA6 diminished the effect of the knockdown of SNHG3 and YTHDF3 and shortened the survival of mice (Figure 6I).

### 3.7 | METTL3-mediated m6A modification expedites ITGA6 translation

METTL3 has been documented as an essential methyltransferase and indispensable for the performance of m6A modification. METTL3 controls RNA expression in an m6A-dependent manner, thereby involving carcinogenesis, tumor progression, and drug resistance in LIHC.<sup>30</sup> Moreover, ITGA6 was associated with the promotion of METTL3 expression in human bladder cancer tissues, and ITGA6 upregulation in patients indicated lower survival.<sup>31</sup> Therefore, we postulated that the METTL3-catalyzed ITGA6 m6A modification was also responsible for the oncogenic role of ITGA6 in LIHC. Surprisingly, we found that m6A methylation of ITGA6 was significantly higher in Huh7/CSC and PLC/PRF/5/CSC than in Huh7 and PLC/PRF/5 cells, respectively (Figure 7A). The StarBase database demonstrated that METTL3 was overexpressed in LIHC (Figure 7B).

In our cohort, METTL3 was highly expressed in LIHC tissues compared with adjacent tissues, and its expression was positively correlated with ITGA6 expression (Figure S3A–B). Overexpression of METTL3 at both the mRNA and protein levels was detected in Huh7/CSC and PLC/PRF/5/CSC but not in Huh7 and PLC/PRF/5 cells (Figure 7C,D). We overexpressed METTL3 in Huh7/CSC and PLC/PRF/5/CSC cells, and RT-qPCR and Western blot analysis verified successful transfection (Figure 7E,F). The global m6A methylation (Figure 7G) and the m6A methylation level of ITGA6 mRNA (Figure 7H) in Huh7/CSC and PLC/PRF/5/CSC cells were remarkably enhanced after ectopic expression of METTL3. RIP experiments confirmed the binding of METTL3 to the ITGA6 mRNA (Figure 7I). Huh7/CSC- and PLC/PRF/5/CSC-overexpressing METTL3 were subjected to YTHDF3 knockdown, and RT-qPCR was conducted to verify the transfection efficiency (Figure 7J). ITGA6 protein expression was elevated after ectopic expression of METTL3, while it was partially decreased after YTHDF3 knockdown (Figure 7K).

### 3.8 | miR-502-3p targets HBXIP to repress METTL3-mediated ITGA6 expression

Interestingly, HBXIP promoted gastric cancer via m6A modification of MYC mRNA governed by METTL3.<sup>32</sup> There was a predicted binding site between miR-502-3p and HBXIP (LAMTOR5) in the Starbase database, and HBXIP was highly expressed in LIHC (Figure 8A). We speculated that miR-502-3p, which inhibited ITGA6 expression by targeting YTHDF3 in LIHC, can also affect METTL3 expression by targeting HBXIP and eventually repress ITGA6.

HBXIP mRNA and protein expression were also significantly elevated in LIHC tissues of our cohort (Figure S3C). Moreover, HBXIP mRNA expression shared a negative correlation with miR-502-3p expression and a positive correlation with METTL3 and ITGA6 expression (Figure S3D). HBXIP mRNA and protein expression was higher in Huh7/CSC and PLC/PRF/5/CSC than in Huh7 and PLC/PRF/5

cells, respectively (Figure 8B,C). In Huh7/CSC and PLC/PRF/5/CSC, depletion of SNHG3 suppressed the expression of HBXIP and METTL3, while miR-502-3p inhibitor upregulated HBXIP and METTL3 (Figure 8D,E). RNA pull-down assays confirmed the binding relationship between miR-502-3p and HBXIP (Figure 8F). Similarly, we mutated the binding sites of miR-502-3p and HBXIP and found that the luciferase activity of Huh7/CSC and PLC/PRF/5/CSC with the mutated binding site was insignificantly affected by miR-502-3p or miR-502-3p inhibitor (Figure 8G).

Next, we performed a knockdown of HBXIP in Huh7/CSC and PLC/PRF/5/CSC, followed by RT-qPCR to verify the knockdown efficiency (Figure 8H). METTL3 expression showed a significant reduction upon sh-HBXIP infection (Figure 8I). As a consequence, the protein expression of HBXIP, METTL3, and ITGA6 was downregulated as well (Figure 8J). Further overexpression of METTL3 was performed on Huh7/CSC and PLC/PRF/5/CSC with HBXIP knockdown, and RT-qPCR showed a significant promotion in METTL3 expression (Figure 8K). A significant increase in ITGA6 protein expression after METTL3 overexpression intervention was observed (Figure 8L). The m6A methylation on ITGA6 mRNA was decreased following HBXIP silencing, which was reversed by METTL3 (Figure 8M). The m6A methylation of ITGA6 was assessed in Huh7/CSC and PLC/PRF/5/CSC with sh-SNHG3 alone or in combination with miR-502-3p inhibitor. SNHG3 knockdown decreased the m6A modification on ITGA6, and miR-502-3p inhibitor increased the m6A modification (Figure 8N).

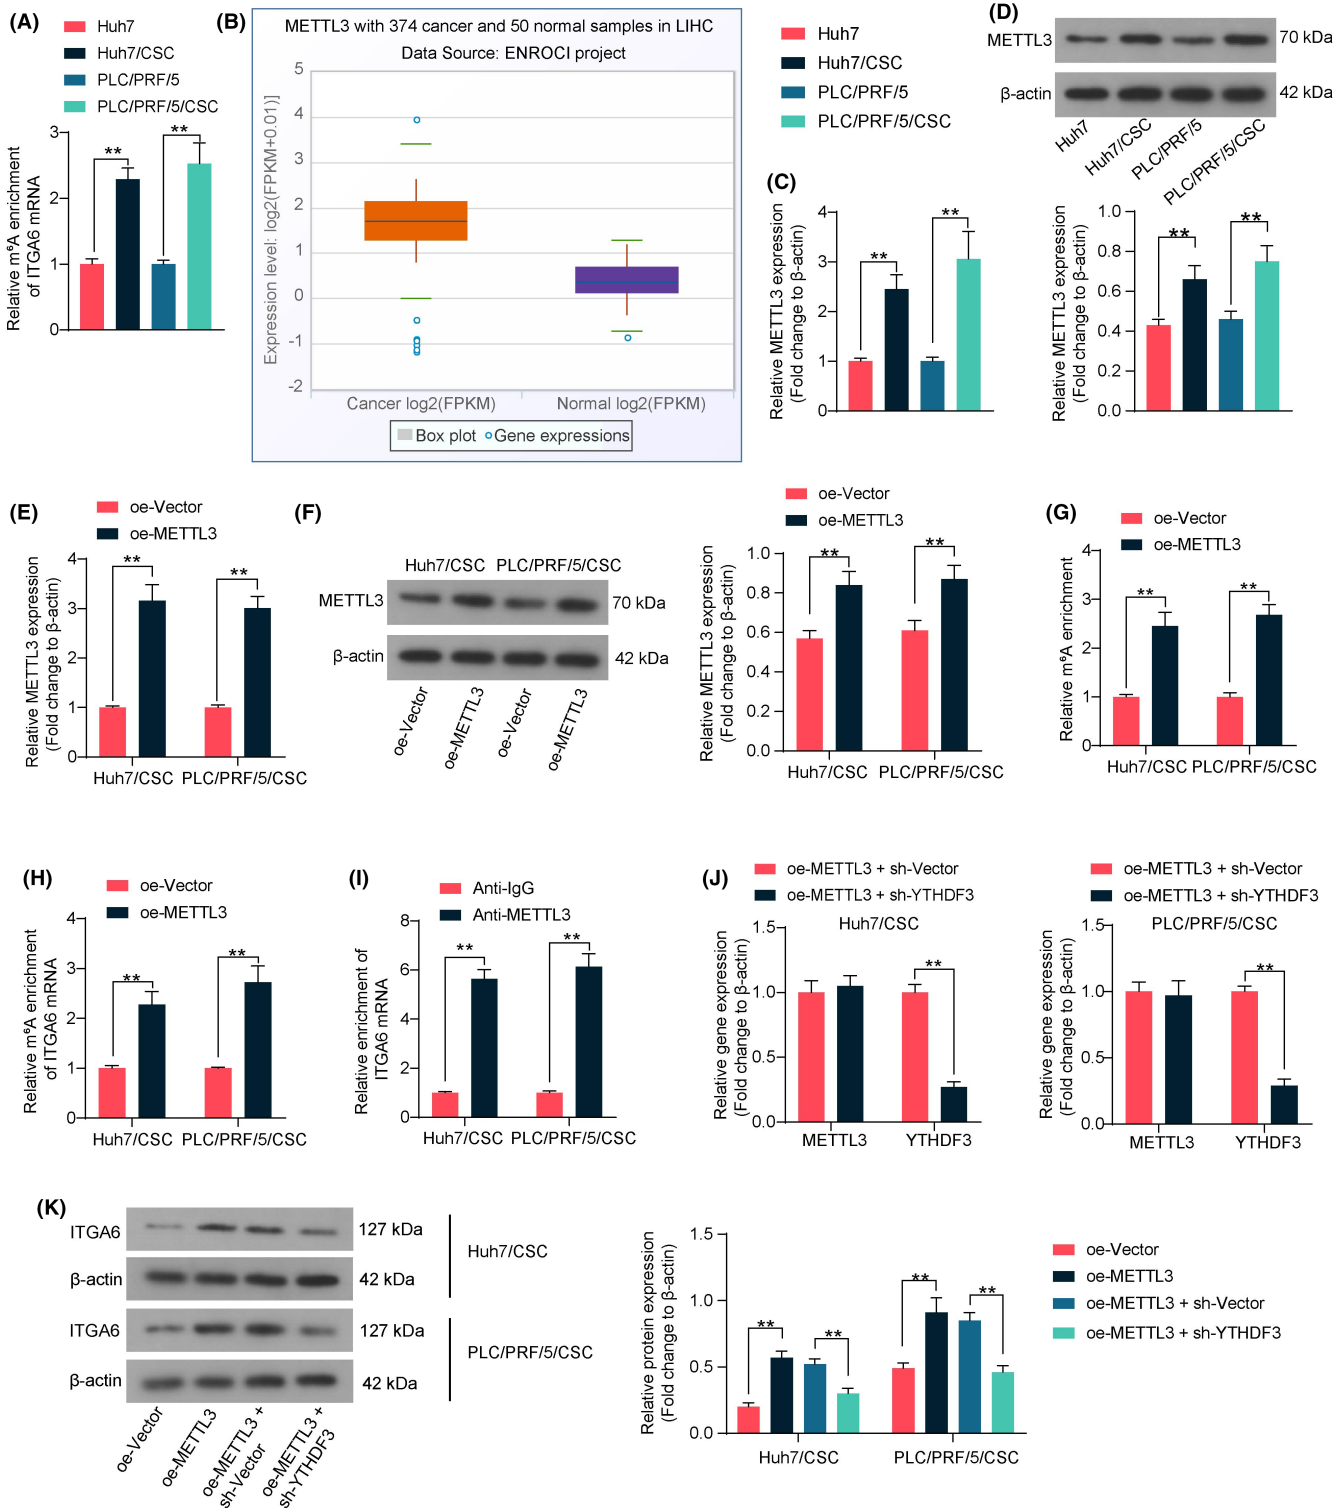

### 3.9 | The HBXIP/METTL3/ITGA6 axis is involved in influencing stemness in LIHC

Western blot showed that suppression of HBXIP resulted in an upregulation in the expression of EpCAM, Nanog, and SOX2, which was reversed by overexpression of METTL3 (Figure S4A). Similarly, the knockdown of HBXIP significantly decreased the colony formation and sphere-forming ability of CSC, and then METTL3 overexpression strengthened the number of colony formation and sphere-forming significantly (Figure S4B,C). Overexpression of METTL3 resulted in increased migratory and invasive activity of CSC in the presence of HBXIP loss (Figure S4D,E).

We demonstrated that (1) SNHG3 was an oncogenic lncRNA and may be a biomarker of LIHC and (2) SNHG3 had effects on LIHC progression by promoting CSC self-renewal through the miR-502-3p-mediated YTHDF3/ITGA6 and HBXIP/METTL3/ITGA6 pathways (Figure 9). The above findings suggest that SNHG3 may become a promising target for LIHC and provide a strategy for LIHC treatment.
