### Abstract

The biological basis for investigating dichlorodiphenyltrichloroethane (DDT) exposure and breast cancer risk stems from *in vitro* and animal studies indicating that DDT has estrogenic properties. The objective of this study was to update a meta-analysis from 2004 which found no association between dichlorodiphenyldichloroethylene (DDE) and breast cancer. We searched PubMed and Web of Science for studies published through June 2012 assessing DDT/DDE exposure and breast cancer. Summary Odds Ratios (ORs) with 95% confidence intervals (CIs) were calculated for the prevalence of breast cancer in the highest versus the lowest exposed groups for DDT and DDE. Difference of means of exposure for cases versus controls was analyzed for DDT and DDE. From the 500 studies screened, 46 were included in the meta-analysis. Slightly elevated, but not statistically significant summary ORs were found for DDE (1.05; 95% CI: 0.93 – 1.18) and DDT (1.02; 95% CI: 0.92 – 1.13). Lipid adjusted difference of means analysis found a significantly higher DDE concentration in cases versus controls (11.30 ng/g lipid;  $p = 0.01$ ). No other difference of means analysis found significant relationships. The existing information does not support the hypothesis that exposure to DDT/DDE increases the risk of breast cancer in humans.

### Keywords

DDT; DDE; Breast Cancer; Systematic Review; Meta-Analysis

### 1. Introduction:

In the 1940s, dichlorodiphenyltrichloroethane (DDT) became the first modern synthetic insecticide and was initially used in both military and civilian settings to combat malaria,

*Disclaimer:* the findings and conclusion in this report are those of the authors and do not necessarily represent the official position of ATSDR.

typhus and other insect-borne human diseases, among other uses (ATSDR, 2002). By the 1960s, its use had become global. However, the United States Department of Agriculture began to implement regulations on many of DDT's uses in response to research implicating its reduced efficacy (namely resistance in a number of insect species) and environmental and toxicological effects (ATSDR, 2002). The U.S. banned DDT in 1972, but its use continues in places such as Africa, in order to control malaria epidemics (ATSDR, 2002; Lopez-Cervantes et al., 2004; Smith, 1999).

Despite its ban in many countries, DDT remains persistent in the environment and in the food chain with a half-life of soil ranging from 2-15 years (ATSDR, 2002; Laden et al., 1999; Snedeker, 2001). DDT and its major metabolites, dichlorodiphenyldichloroethylene (DDE) and dichlorodiphenyldichloroethane (DDD), are lipophilic and therefore, have long half-lives via bioaccumulation in body fat. DDT has a half-life in serum of about 10 years; the half-life in adipose varies depending on individual fat composition and DDE has an even longer half-life, estimated at 4.2-5.6 years on a population basis (ATSDR, 2002; Smith, 1999). It has been suggested that DDT exposure may be associated with breast cancer because *in vitro* and animal studies have shown DDT to have estrogenic properties (Longnecker et al., 1997). Because increased estrogen levels have been linked with breast cancer, it is possible that exposure to DDT may increase breast cancer risk (Longnecker et al., 1997).

In the past twenty years, a number of epidemiological studies have been conducted to investigate the potential relationship between DDT exposure and breast cancer risk. Wolff et al. (1993) were the first to find a positive association between exposure to DDE and breast cancer risk. Many subsequent studies, however, failed to replicate these results (reviewed in Lopez-Cervantes et al., 2004). The available literature presents heterogeneous study designs, as shown by the meta-analyses conducted by Lopez-Cervantes and colleagues (2004). For example, although the biological proxies for DDT exposure have primarily been blood serum and breast adipose (Lopez-Cervantes et al., 2004), adipose obtained from biopsy samples taken from the abdomen and buttocks have been used to overcome bias associated with using benign breast disease control populations (Raaschou-Nielsen et al., 2005; van't Veer et al., 1997). Additionally, the methods used to control for the effect of circulating lipids on serum concentrations of DDT and its metabolites varied across studies (Lopez-Cervantes et al., 2004). This lack of standardization across studies presents a potential reason for the failure to find an association between exposure and breast cancer risk. Two meta-analysis studies have evaluated the available literature on DDT exposure and breast cancer risk (Laden et al., 2001a; Lopez-Cervantes et al., 2004). Since the 2004 meta-analysis, 12 new epidemiological studies investigating the relationship between DDT/DDE exposure and breast cancer risk were published -- including three nested case-control studies. Here we present a systematic review and meta-analysis assessing whether the most recent epidemiological studies support the hypothesis that DDT exposure increases the risk of breast cancer in the female population using both OR and mean exposure as effect size measures.

## 2. Methods:

### 2.1 Study Selection:

PubMed and Web of Science databases were searched through June 2012 for English-language publications. The following keywords search strategy were used: {"breast neoplasms"[MeSH Terms] OR ("breast"[All Fields] AND "neoplasms"[All Fields]) OR "breast neoplasms"[All Fields] OR ("breast"[All Fields] AND "cancer"[All Fields]) OR "breast cancer"[All Fields] OR "mammary glands, human"[MeSH Terms] OR { ("mammary"[All Fields] AND "glands"[All Fields] AND "human"[All Fields]) OR "human mammary glands"[All Fields] OR ("mammary"[All Fields] AND "gland"[All Fields]) OR "mammary gland"[All Fields] AND ("ddt"[MeSH Terms]) OR "ddt"[All Fields] OR "dichlorodiphenyltrichloroethane"[All Fields] OR (1[All Fields] AND 1-dichloro-2[All Fields] AND 2-bis[All Fields]) AND 4-chlorophenyl[All Fields] AND ("ethylene"[Supplementary Concept] OR "ethylene"[All Fields] OR "ethylenes"[MeSH Terms] OR "ethylenes"[All Fields])} OR {dde[All Fields] OR dimic[All Fields] OR ("dimethylaminonaphthalene-5-sulfonaminoethylmethylamine"[Supplementary Concept] OR "dimethylaminonaphthalene-5-sulfonaminoethylmethylamine"[All Fields] OR "ddns"[All Fields]) OR ("ddt"[MeSH Terms] OR "ddt"[All Fields]) AND dehydrochloride[All Fields] OR ("dichlorodiphenyl dichloroethylene"[MeSH Terms] OR ("dichlorodiphenyl"[All Fields] AND "dichloroethylene"[All Fields]) OR "dichlorodiphenyl dichloroethylene"[All Fields] OR "dichlorodiphenyldichloroethylene"[All Fields]) OR "dichlorodiphenyl dichloroethene"[All Fields]}

References cited in the selected articles were also reviewed for potentially eligible studies. Studies were *a priori* excluded according to the following criteria: 1) commentary; 2) contained duplicate data (e.g. used the same data/cohort as a study already included in the pool of eligible studies); 3) did not have data on the control group; 4) did not have exposure data; 5) did not have breast cancer risk data or that the risk could not be calculated based on the data available. Also, we excluded studies that were not published in English.

The *a priori* eligibility criteria of the studies to be included in the analyses are the following: (i) the paper must examine a correlation between breast cancer and DDT/DDE exposure; and (ii) the study must have primary human data (e.g. no animal studies, review papers, etc.)

### 2.2 Data Extraction:

The following data was extracted for each study: Study authors, publication year, country of study, study years, study design, sample type, mean exposure level and standard deviation, OR and corresponding 95% CI, and any factors used for adjustment of mean exposure levels and/or odds ratios. All data were extracted independently by two authors (F.S. and S.I.).

### 2.3 Statistical Analysis:

Summary odds ratio and 95% confidence intervals were estimated by comparing the number of breast cancer patients whose blood DDT/DDE concentrations fell in the highest range versus the number of patients whose samples had the lowest concentrations. ORs were pooled based on random-effects (where all studies estimate an average of a distribution of

true effect size) modeling. Cut points for the different concentration groups varied from study to study. Thus, the highest versus the lowest exposure groups were determined based on the specifications within each study. We stratified according to menopausal status to look for potential differences in breast cancer risk among cases diagnosed with pre-menopausal versus post-menopausal breast cancer. The literature suggests that there is a difference between pre-menopausal and post-menopausal breast cancer due to difference in lifetime exposure to estrogen. Research done by the Collaborative Group on Hormonal Factors in Breast Cancer (2012) found that premenopausal women had a greater risk of breast cancer than postmenopausal women of similar age.

For the difference of means analysis, effect size was calculated by the difference between the mean DDT/DDE exposure of the breast cancer cases and the control group (comparison group without breast cancer). Each mean difference was weighted according to the inverse of its variance, and the average was taken (weighted mean difference, or WMD). The WMD in each study was pooled using a random-effects model. Results are given with 95% confidence intervals. Data were analyzed using the Comprehensive Meta-Analysis (CMA) software, version 2.

Between-study heterogeneity in the results of the studies was assessed using a chi-square test and the  $I^2$  measure of inconsistency based on both fixed- and random-effects modeling. Significant heterogeneity was defined as a chi-square test  $p$ -value  $< 0.1$ .  $I^2$  takes values between 0% and 100% with higher values denoting a greater degree of heterogeneity ( $I^2 = 0-25\%$ : no heterogeneity;  $I^2 = 25-50\%$ : moderate heterogeneity;  $I^2 = 50-75\%$ : large heterogeneity; and  $I^2 = 75-100\%$ : extreme heterogeneity) (Higgins et al., 2003). When heterogeneity was moderate to extreme, we stratified our analysis by study design (case-control versus nested case-control), by control group (hospital-based versus population-based), and by sample type (blood serum versus adipose tissue). In addition to stratification analyses, we conducted also meta-regression analyses against the above covariates as a comparison measure of heterogeneity.

Case control design study assesses DDT body burdens at or shortly before the time of breast cancer diagnosis. The clinical diagnosis of cancer is different than the time when cancer began to develop, and this is particularly relevant for cancers that exhibit a long latency. Furthermore, the biological monitoring of DDT presents its own potential for epidemiological bias since serum levels can also be influenced by factors that relate directly to the outcome of interest such as weight change. The weight loss experienced by cancer patients in advanced stages will mobilize the DDT/DDE stored in the adipose tissues and thus increase the serum levels. This potential bias may be overcome with the use of a nested case-control study design. A nested case-control study depends on the pre-existence of a cohort that has been followed over time. The cohort is assembled in such a way that information on exposure is collected on all subjects at baseline before the occurrence of the disease occurrence, such as blood sample taken and stored. When a case of the outcome of interest is identified, samples of the cohort who have not developed the outcome by that time are selected as controls. The advantage of the nested case-control design is that the most appropriate control group is chosen from members of the same cohort who have not developed the outcome at the time that they are chosen.

Publication bias was assessed using the methods proposed by Begg and Mazumdar (1994) and by Egger et al. (1997). All p-values are two-tailed.

### 3 Results:

#### 3.1 Study Results:

The initial search yielded 627 studies, 127 of which were duplicates. Of the 500 remaining studies screened based on title and abstract, we excluded 369 because they did not contain all of the search query terms pertaining to DDT/DDE and breast cancer. Thus leaving 131 studies for full-text screening. (Figure 1). The eligibility process excluded 80 studies, leaving 51 studies for the exclusion process. All 51 of these studies were suitable for qualitative synthesis. Table 1 presents the studies excluded from the meta-analyses – either based on whether the weighted mean difference or the OR was the effect size, or both, , leaving 46 studies for meta-analyses as detailed in Table 2 and Table 3. . Thirty-one of these studies contained enough information to be included in the difference of means analysis. Forty of the studies contained enough information for inclusion in the odds ratio meta-analysis.

#### 3.2 DDE and Breast Cancer:

Overall, the summary odds ratio evaluating the risk of breast cancer from DDE exposure was slightly elevated but not statistically significant (OR = 1.04; 95% CI: 0.94 – 1.15) (Figure 2 and Table 4). There was no publication bias among the studies (Begg p-value = 0.09, Egger's p-value = 0.14) and heterogeneity was moderate ( $I^2 = 31.14$ ). To resolve this moderate heterogeneity, the results were stratified by study design and tissue sample. The OR for the nested case control studies was 0.90 (95% CI: 0.75 – 1.08). Further stratification of the nested case control by tissue type did not yield significant results (adipose tissue OR = 0.70, 95% CI: 0.45 – 1.08; and blood serum OR = 0.95, 95% CI: 0.78 – 1.17). The OR for case control studies was found not significant (OR = 1.11; 95% CI: 0.98 – 1.25), and stratification by tissue sample indicates no association (Table 4) Interestingly, stratification by blood serum case-control studies showed a statistically significant higher odds of having breast cancer in the highest exposed group compared to the lowest (OR = 1.15; 95% CI: 1.01 – 1.39). One potential explanation for this significant outcome is that case-control studies exhibited higher heterogeneity than the nested case-control studies. Heterogeneity analyses using meta-regression with random effects yielded null log-likelihood ratio p-values as well as low  $\tau^2$  values also indicating that there was moderate heterogeneity (Table 5).

For the DDE and breast cancer difference of means meta-analysis, results were stratified by whether or not the study was lipid adjusted or not. In the studies that reported exposure levels unadjusted for lipids, the differences of means between cases and controls was null (0.45 ng/mL, SE = 0.85, p = 0.60) (Table 6). Heterogeneity was high in these studies, even after stratifying for design, control population, and difference of means rank. There was not a publication bias reported in these studies (Begg p-value = 0.83, Egger's p-value = 0.58). For the lipid adjusted studies, there was a statistically significant higher DDE concentration in cases compared to controls (110.30 ng/g lipid, SE = 44.94, p = 0.01) (Table 6).

**3.2.1 DDE and Menopausal Status Analysis:** Stratification based on menopausal status found no statistically significant higher breast cancer risk for either pre- (OR = 1.165, 95% CI: 0.98 – 1.48) or post-menopausal (OR = 1.23, 95% CI: 0.94 – 1.61) stratification (Figure 3). We also found no heterogeneity ( $I^2 = 0.00$ ) for both pre- and post-menopausal stratification. We did not find any publication bias (Begg's p-value = 0.44, Egger's p-value = 0.43).

### 3.3 DDT and Breast Cancer:

Overall, the summary odds ratio for DDT exposure and breast cancer was slightly elevated but not statistically significant (OR = 1.02, 95% CI: 0.92 – 1.13) (Table 4). There was no publication bias found (Begg's = 0.23; Egger's = 0.12); however, there was high heterogeneity ( $I^2 = 64.49$ ). Stratification by study design yielded similarly null results (Nested case control OR = 0.85, 95% CI: 0.56 – 1.28; Case Control OR = 0.99, 95% CI: 0.99 – 1.00). And further stratification by tissue sample type yielded comparable results. This stratification by study design and tissue sample showed that the high level of heterogeneity we observed was solely due to the Nested Case Control studies (Case Control  $I^2 = 0.00$ ; Nested Case Control  $I^2 = 70.76$ ). .

Similarly to the DDE and breast cancer difference of means meta-analysis, results for DDT and breast cancer difference of means analysis were stratified by whether or not the study was lipid adjusted or not. In the studies that reported exposure levels unadjusted for lipids, the differences of means between cases and controls was null (0.45 ng/mL, SE = 0.37, p = 0.23) (Table 6). In the lipid adjusted DDT studies, there was no difference in exposure between the cases and controls (–0.09 ng/g lipid, SE = 0.08, p = 0.28) (Table 6).

## 3. Discussion:

The results of this meta-analysis showed that the most recent body of literature does not support a relationship between DDT/DDE and breast cancer risk. We found that those exposed to the highest levels of DDT and DDE compared to those exposed to the lowest levels had a slightly elevated but not statistically significant risk of breast cancer (DDE Summary OR = 1.04, 95% CI: 0.94 – 1.15; DDT Summary OR = 1.02, 95% CI: 0.92 – 1.13). Although breast cancer patients had slightly elevated levels of DDE, the null summary OR does not indicate that DDE exposure is associated with breast cancer risk.

Overall, we observed moderate to high levels of heterogeneity among the mean exposure data even after stratification by study design and sample type. For example, even after stratifying by type of control group, tissue type and difference of means rank, the high degree of heterogeneity of the case control studies that presented mean lipid unadjusted DDE serum concentrations could not be resolved. One possible explanation for the heterogeneity among the mean exposure studies data is the fact that mean exposure represents a crude effect measure that is unadjusted for other confounders, such as exposure level and genetic markers for breast cancer. The moderate heterogeneity observed in the OR studies could be attributed to the large variety of adjustment factors. We found a lack of standardization with regard to the combination of factors accounted for in the adjustment of the crude OR among the studies used in this meta-analysis.

The quality of chemical exposure assessment may be a cause of heterogeneity. There were differences on specificity and sensitivity in the methodology used to assess DDE or DDT level in tissues. These factors may affect the results of the difference of means analyses by creating between-study heterogeneity by influencing the differences between the highest versus lowest exposure groups. However, the quality of the exposure assessments would have a minor impact on the pooled OR analyses, since this is a unit-less measure (ratio) comparing highest vs. lowest exposure group in the same cohort, and therefore enables comparison across studies.

Despite the fact that the most common methodological approach used in the studies included in this meta-analysis was the case control design, which has the disadvantage that DDT/DDE tissue levels at diagnosis may be considerably different than those at the time of cancer onset, we found little indication that the study design was related to the conflicting results in the studies analyzed. Our results support the notion that the nested case-control design, which depends on the pre-existence of a cohort that has been followed over time, is the preferred method when looking for a causal relationship between exposure and disease risk because these studies generally showed lower levels of heterogeneity than the case-control studies. However, both study designs showed low to moderate heterogeneity, supporting the idea that the study type did not affect our results. Additionally, we found only limited evidence that sample type may affect results. Stratifying the OR analysis for DDE and breast cancer by blood serum samples within the case control studies yielded a statistically significant association between DDE and breast cancer (OR = 1.15, 95% CI: 1.01-1.32). However, there was high heterogeneity among these studies indicating that there may be other factors affecting these results.

The inconsistency found among the epidemiological studies included in our meta-analysis could be due to confounders that distort the relationship between DDT/DDE exposure and breast cancer risk. Many of the studies adjusted for common variables (i.e. age, BMI, family history of breast cancer, etc.) (Table 2 and 3). However, not many of the studies adjusted for breast feeding and diet, both of which have been related to DDT/DDE body burden (Bradman et al., 2007). Lactation has been shown to help eliminate body levels of DDT/DDE in addition to helping decrease the risk of breast cancer. It is known that DDT/DDE remains in the food chain despite its ban, thus exposure through diet is a common problem (Laden et al., 1999; Snedecker, 2001). If studies do not account for these confounding variables, then the results may be skewed. Because we stratified our analysis and found generally low heterogeneity among our results, this lack of control for these variables does not seem to be significant. However, this is not enough to dismiss the possibility of differences among studies being explained by confounding variables.

Recently, there has been increasing indications that the age at which one is exposed to chemicals such as DDT may play a direct role in one's risk for a disease. Organotins, such as tributyltin, are a good example of this. There has been much evidence suggesting that exposure to organotins *in utero* can act as a causative agent for obesity in adulthood through epigenetic changes that alter transcription in the adipogenesis pathway (Grün et al., 2006). Because of this perceived mechanism, more research has begun to investigate how chemical exposure at different ages can differentially affect disease progression and expression. Cohn

et al. (2007) reported that exposure to DDT before the age of 14 significantly increased the likelihood of developing breast cancer. They looked at a cohort of individuals who had blood samples drawn when DDT was still used in the United States (1959-1967), ensuring that the exposure level would be high among all of the individuals. They found a significant increase in the level of DDT within the cases of their cohort (those who developed breast cancer) as compared to their age-matched controls; however, this significance was found to be derived primarily from the group of cases who were younger than 14 at the time of the highest DDT exposure. This suggested that age at exposure to DDT has a direct effect on the prevalence of breast cancer within a population, providing further evidence that effects from environmental exposure may be influenced by the stage of development during exposure.

In a review paper, Cohn (2003) notes that DDT and DDE can cross into the placenta during pregnancy, thus representing a potential mechanism for fetal exposure. Moreover, a number of studies support the hypothesis that breast cancer may have fetal origins. For instance, higher birth weight and exposure to synthetic estrogen *in utero* appear to be associated with an increased risk of breast cancer (Michels & Xue, 2006; Palmer et al., 2006). However, fetal characteristics such as birth weight are indirect measures of the relationship between *in utero* development, hormonal exposures and breast cancer risk; furthermore, these studies are unable to pinpoint specific developmental events during which exposures to hormones, organochlorine pesticides, and other estrogenic substances may initiate future breast cancer development (Troisi et al., 2007). This represents a significant gap in our understanding of disease progression related to age at time of exposure and supports the need for more research to be done within this area.

The idea that exposure during specific developmental windows may affect the prevalence of a given outcome is further supported by the relationship between DDT/DDE exposure and age at menarche. Ouyang et al. (2005) used a cross sectional study of 466 women in China to show that women exposed to the highest quartile of DDT/DDE had a statistically significant lower age at the time of menarche than those exposed to the lowest quartile. This study is important to note because DDT was not banned in China until 1984; the women in this study were 21-34 years of age at the time of blood sample collections in 1998. Therefore, these women were exposed to high levels of DDT from birth for between 7 and 21 years when DDT was being used as well as exposure to remnants of the chemical after the ban since DDT is persistent in the environment. Furthermore, it has been shown that an earlier age of menarche statistically increases the risk of breast cancer (Collaborative Group on Hormonal Factors, 2012). This supports the idea that early exposure *in utero* and during childhood and adolescence to DDT/DDE and other environmental toxins may lead to an increased risk of disease by acting to affect normal developmental stages. Because not many of the studies incorporated into our meta-analysis controlled for age of menarche, there may have been an understatement on the risk of exposure due to confounding. Future studies should make attempts to control for this factor as well as the age of exposure in order to take into consideration the mass of new information relating developmental stage during exposure and the potential for an increased risk of adult-onset diseases.

A limitation of the OR pooled analyses is that the chemical blood burden range defining the lowest referent group, as well as the highest level group, is different across the studies. This

is based on the time the study was conducted, and reflects, also, the policies regulating the use of the chemicals: for example, the level of exposure to DDT has dramatically decreased in US since the use of DDT was banned. However, the high and low group are based on the exposure level of the investigated cohort, and since the OR are unit-less measure, the pooled OR across the studies still has its merit.

Another potential limiting factor of this study is that it does not rule out the possibility that exposure to mixtures of DDT and other organochlorine pesticides and common chemicals with estrogenic properties may pose an increased breast cancer risk. Some recent *in vitro* studies suggest that interactions between these chemicals, endogenous and/or exogenous hormones, and their ligands and receptors may lead to homeostatic changes in hormonal concentrations in mammary tissue that can induce malignant conversion of cells (Aube et al., 2011; Valeron et al., 2009). While our systematic review yielded some studies evaluating breast cancer risk associated with exposures to other chemicals such as PCBs, HCB, beta-HCH, Dieldrin, and trans-nonachlor, they failed to examine the breast cancer risk associated with these combined chemical exposures. For example, in their population-based retrospective study, Boada et al. (2012) found that 24.3% of their breast cancer patient blood samples contained a mixture of aldrin, DDE and DDD not found in healthy subjects, but the breast cancer risk associated with exposure to the mixture was not calculated. Thus, the relationship between breast cancer and mixtures of pesticides and other chemical mixtures represents an important area in need of further investigation.

The results of our meta-analysis do not support an association between DDT and DDE exposure and the risk of breast cancer. Although we cannot completely rule out a very small effect from exposure, based on previous findings in similarly conducted meta-analyses as well as the high number of studies that we were able to analyze, we believe that this study further confirms the evidence against a relationship between DDT and breast cancer risk.

Studies Excluded from DDE Meta-Analysis.

Excluded From Difference of Means Analysis									
Study + Pub Date & State, Country	Cases/ Controls (n)	Control Group(s)	Biologic Specimen Type + Year of Collection	Study Design	Case vs. Control Mean (SD) + Statistical Significance	Units	OR (95% CI)	Reason For Exclusion	
Aronson et al.2000; Canada	217/213	BBD	Adipose, 1995-1997	CC	693 vs. 596 <sup>a</sup> ; p<.05; S.S.	ng/g lipid	1.62 (.84-3.11)	Geometric Mean & SD, No SD or SE Data	
Bagga et al.2000; California, USA	73/73	HC	Adipose, 1995-1996	CC	800 vs. 709.1; p= .23; N.S.	ng/g lipid	1.126 (.79-1.60)	No SD or SE Data	
Cohn et al.2007; California, USA	129/129	PC	Blood Serum, 1959-1967	nested	-	-	1.00 (.4-2.4)	Mean Exposure Not Reported	
Dorgan et al. 1999; Missouri, USA	105/208	PC	Blood Serum, 1977-1987	nested	-	-	.8 (.4-1.5)	Mean Exposure Not Reported	
Gammmon et al.2002; New York, USA	643/429	PC	Blood Serum, 1996-1997	CC	671.96 (2.76) vs. 645.74 (2.59) <sup>d</sup> ; p=.52; N.S.	ng/g lipid	1.2 (.76-1.9)	Geometric Mean & SD	
Hoyer et al.1998; Denmark	240/477	PC	Blood Serum, 1976	nested	-	-	.88 (.56-1.38)	Mean Exposure Not Reported	
Hoyer et al.2000; Denmark	155/274	PC	Blood Serum, 1976-1978	nested	-	-	1.4 (.7-2.8)	Mean Exposure Not Reported	
Ibarrutza et al.2004; Spain	198/260	HC	Adipose, 1996-1998	CC	326.86 (2.78) vs. 307.24 (3.62) <sup>d</sup> ; p=.57; N.S.	ng/g lipid	1.22 (.68-2.20)	Geometric Mean & SD	
Itoh et al.2009; Japan	403/403	HC	Blood Serum, 2001-2005	CC	360 vs. 370 <sup>b</sup> ; p=.1; N.S.	ng/g lipid	1.02 (.46-2.26)	Median, No SD or SE	
Iwasaki et al.2008; Japan	139/278	PC	Plasma, 1990-2002	nested	7.04 vs. 6.08 <sup>b</sup> ; p=.42; N.S.	ng/mL	1.48 (.7-3.13)	Median, No SD or SE	
Laden et al.2001; USA	372/372	PC	Blood Serum, 1989-1994	nested	768 (788) vs. 372 (817) <sup>b</sup> ; p=.28; N.S.	ng/g lipid	.82 (.49-1.37)	Median, No SD or SE	
Liljgren et al.1998; Sweden	43/35	HC (BBD)	Adipose, 1993-1995	CC	767 vs. 1026; N.S.	ng/g lipid	.4 (.2-1.2)	No SD or SE	
Mendonca et al.1999; Brazil	177/355	HC	Blood Serum, 1995-1996	CC	5.1 vs. 4.8; p=.93; N.S.	ng/mL	.83 (.4-1.6)	No SD or SE	
Moysich et al.1998; New York, USA	154/192	PC	Blood Serum, 1986-1991	CC	11.47 (10.49) vs. 10.77 (10.64); N.S.	ng/mL	1.34 (.71-2.55)	Adjusted Mean	
Pavuk et al.2003; Slovakia	24/88	PC	Blood Serum, 1998-1999	CC	4912.1 vs. 3129.1 <sup>d</sup> ; p=.04; S.S.	ng/g lipid	3.04 (.65-14.3)	Geometric Mean, No SD or SE	
Raaschou-Nielsen et al.2005; Denmark	409/409	PC	Adipose, 1993-1997	nested	639 vs. 686.3; statistical significance not reported, but authors noted that controls had	ng/g lipid	.7 (.5-1.2)	No SD or SE	

Study + Pub Date & State, Country	Cases/Controls (n)	Control Group(s)	Biologic Specimen Type + Year of Collection	Study Design	Case vs. Control Mean (SD) + Statistical Significance	Units	OR (95% CI)	Reason For Exclusion
Romieu et al.2000; Mexico	120/126	PC	Blood Serum, 1990-1995	CC	slightly higher concentrations than cases 3840 vs. 2510; p=.02; S.S.	ng/g lipid	3.81 (.1-14-12.8)	No SD or SE
Rubin et al.2006; Alaska, USA	63/63	PC	Blood Serum, 1981-1987	CC	8.67 vs. 7.36 <sup>d</sup> ; p=.02; S.S.	ng/mL	1.43 (.46-4.47)	Geometric Mean & SD, No SD or SE
Stellman et al. 2000; New York, USA	232/323	HC (BBD)	Adipose, Not Specified	CC	419.2 vs. 374.1 <sup>b</sup> ; p=.2; N.S.	ng/g lipid	.74 (.39-1.25)	Median, No SD or SE
vant Veer et al. 2000; Various European Countries	265/341	PC & HC	Adipose, 1991-1996	CC	1350 vs. 1510; p=.36; N.S.	ng/g lipid	.48 (.25-.95)	No SD or SE
Wolff et al.2000; New York, USA h	161/339	HC	Blood Serum, 1994-1996	CC	610 (3020) vs. 660 (2730) <sup>d</sup> ; N.S.	ng/g lipid	.93 (.56-1.5)	Geometric Mean & SD
Wolff et al.2000; New York, USA p	110/213	PC	Blood Serum, 1987-1992	nested	977 (2460) vs. 1097 (2290) <sup>d</sup> ; N.S.	ng/g lipid	1.3 (.51-3.35)	Geometric Mean & SD
Zheng et al.1999; Connecticut, USA	304/186	HC (BBD)	Adipose, 1994-1997	CC	736.5 vs. 784.1 <sup>d</sup> ; p=.41; N.S.	ng/g lipid	.9 (.5-1.5)	Geometric Mean, No SD or SE
Zheng et al.2000; Connecticut, USA	475/502	PC & HC	Blood Serum, 1995-1997	CC	460.1 vs. 456.2; p=.89; N.S.	ng/g lipid	.95 (.68-1.32)	Geometric Mean, No SD or SE
<b>Excluded From Odds Ratio Analysis</b>								
Ahmed et al.2002; Egypt	43/11 (BBD)/21 (PC)	BBD & PC	Blood Serum, 1999-2000	CC	41 (5.2) vs. 48 (6.2), 41 (5.2) vs. 31 (2.5); P=.03; S.S. ("of borderline statistical significance")	ng/mL	-	OR Not Reported
Mathur et al.2002; Rajasthan, India	135/50	HC	Blood Serum, Not Specified	CC	862 (154) vs. 47 (18); p<.05; S.S.	ng/mL	-	OR Not Reported
Ociepa-Zawal et al. 2010; Poland	54/23	HC	Adipose, Not Specified	CC	956 (771) vs. 631 (371); N.S., but significant differences (p=.006) found in patients with late onset breast cancer	ng/g fat	-	OR Not Reported
Siddiqui et al.2005; Delhi, India	25/25	HC (BBD)	Blood Serum, Not Specified	CC	11.69 (3.29) vs. 20.22 (8.24); p=.56; N.S.	ng/mL	-	OR Not Reported
Unger et al. 1984; Denmark	14/21	HC (BBD)	Adipose, Not Specified	CC	1230 (630) vs. 1250 (760); N.S.	ng/g lipid	-	OR Not Reported
Waliszewski et al.2005; Mexico (Breast Cancer Cases)	127/127	HC	Adipose, Not Specified	CC	980 (627) vs. 782 (282); p<.05; S.S.	ng/g lipid	-	Relative Risk
Waliszewski et al.2005; Mexico (BBD Cases)	127/127	HC	Adipose, Not Specified	CC	1761 (1090) vs. 782 (282); p<.05; S.S.	ng/g lipid	-	Relative Risk
<b>Excluded From Both Analyses</b>								

Study + Pub Date & State, Country	Cases/Controls (n)	Control Group(s)	Biologic Specimen Type + Year of Collection	Study Design	Case vs. Control Mean (SD) + Statistical Significance	Units	OR (95% CI)	Reason For Exclusion
Cassidy et al. 2005; Texas, USA	17/17	HC (BBD)	Adipose, 1994-1998	CC	975 vs. 949 <sup>b</sup> ; N.S.	ng/g lipid	-	Median, No SE or SD Data, OR Not Reported
Dewailly et al. 1994 (ER+ Case Population); Quebec, Canada	9/17	HC (BBD)	Adipose, 1991-1992	CC	608.9 (338.9) vs. 765.3 (526.9); p=.63; N.S.	ng/g lipid	-	Only Stratified Data Reported, OR Not Reported
Dewailly et al. 1994 (ER+ Case Population); Quebec, Canada	9/17	HC (BBD)	Adipose, 1991-1992	CC	2132.2 (204.9) vs. 765.3 (526.9); p=.01; S.S.	ng/g lipid	-	Only Stratified Data Reported, OR Not Reported
Guttes et al. 1998; Germany	45/20	HC (BBD)	Adipose, 1993-1994	CC	838 vs. 450	ng/g lipid	-	No SD or SE, OR Not Reported
Ward et al. 2000; Norway	72/72	PC	Blood Serum, 1973-1991	CC	1230 vs. 1260; p=.84; N.S.	ng/g lipid	-	No SD or SE, OR Not Reported

BBD - benign breast disease, HC - hospital control group, PC - population control group, SD - standard deviation, SE - standard error, OR - odds ratio, ER - estrogen receptor, N.S. - not statistically significant, S.S. - statistically significant. <sup>a</sup>Geometric Mean & Standard Deviation, <sup>b</sup>Media

Table 2 –

Characteristics of studies included in DDE Meta-Analysis

Study + Pub Date; Study Site	Cases/Controls (n)	Control Group(s)	Biologic Specimen Type, Year of Collection	Study Design	DDE Concentration, mean (SD)				
					Cases	Controls	Units of Exposure	p-value	Study Conclusion
Cohn et al.2007; California, USA	129/129	PC	Blood Serum, 1959-1967	nested	-	-	-	-	-
Krieger et al.1994; California, USA	150/150	PC	Blood Serum, 1964-1971	nested	43.3 (25.9)	43.1 (23.7)	ng/mL	-	-
