The Streptomyces K15 DD-peptidase/penicillin-binding protein

Active site and sequence of the N-terminal region

*Service de Microbiologie, Université de Liège, Institut de Chimie, B6, B-4000 Sart Tilman (Liège 1), Belgium, and †Laboratorium voor Microbiologie, Rijksuniversiteit-Gent, K. L. Ledeganckstraat 35, B-9000 Gent, Belgium

The N-terminal region of the Streptomyces K15 DD-peptidase/penicillin-binding protein shows high homology with that of other penicillin-interactive proteins or domains. The active-site serine residue of the conserved tetrad Ser-Xaa-Xaa-Lys occurs at position 35. There is no indication for the presence of a signal peptide or an N-terminal hydrophobic sequence, suggesting that the Streptomyces K15 enzyme is probably anchored to the membrane by a C-terminal peptide segment.

INTRODUCTION

The membrane-bound $26000 - M_r$ DD-peptidase of Streptomyces K15 catalyses acyl-transfer reactions with cyclic β -lactam and non-cyclic amide and ester carbonyl donors via formation of an acyl-enzyme that involves an essential serine residue [1,2]. The acyl-enzymes formed by reaction with β -lactam antibiotics have long half-lives [3]. Consequently, the DD-peptidase behaves as a penicillin-binding protein (PBP). The peculiarity of the low- M_r , Streptomyces K15 DD-peptidase/PBP is that when acting on an amide substrate such as Ac_a-L-Lys-D-Ala-D-Ala it functions almost exclusively as a strict transpeptidase [1]. In water, hydrolysis is negligible because the D-alanine that is released during enzyme acylation is effectively re-utilized in a transfer reaction that maintains the concentration of the amide carbonyl donor at a constant level. In the presence of an exogenous amino compound such as Gly-Gly, the acceptor activity of which overcomes that of water and D-alanine, the substrate is quantitatively converted into the transpeptidated product Ac₂-L-Lys-D-Ala-Gly-Gly. As a basis for the design of nucleotide probes that would help identifying the gene that encodes the Streptomyces K15 DD-peptidase, the N-terminal region of the purified enzyme was sequenced and the essential serine residue was identified by active-site peptide mapping.

MATERIALS AND METHODS

Sequence of the *N*-terminal region of the DD-peptidase

The enzyme (4.9 nmol in $130 \ \mu$ l), purified in the presence of cetyltrimethylammonium bromide as described previously [4], was supplemented with 5 vol. of cold (-20 °C) acetone and maintained at -20 °C for 30 min, after which time the precipitated enzyme was collected by centrifugation at 20000 g for 30 min. The pellet was washed with 4 vol. of cold acetone, dissolved in trifluoroacetic acid and the solution supplemented with an equal volume of water. Automated sequence analysis of 4.9 nmol of protein was carried out on a

470 A gas-phase Sequenator. The amino acid phenylthiohydantoin derivatives were analysed off-line the sequencer on a 4.6 mm × 250 mm IBM cyanopropyl column (Biotech Instruments, Hertford, Herts., U.K.) as described in ref. [5]. The h.p.l.c. set-up consisted of an Intelink System connected to a 440 fixed-wavelength detector (Waters, Milford, MA, U.S.A.) set at 254 and 313 nm. Automated sequence analysis of 1.4 nmol of protein was also carried out on a 477 A pulsed-liquid Sequenator (Applied Biosystems, Foster City, CA, U.S.A.). The amino acid phenylthiohydantoin derivatives were analysed on-line the sequencer on a 21 mm × 220 mm C₁₈ MPLC Cartridge column (Applied Biosystems) as described by the manufacturer.

Preparation of the acyl- ([³⁵S]benzylpenicilloyl-)enzyme

The enzyme (20 nmol) was incubated for 15 min at 37 °C with [³⁵S]benzylpenicillin (230 nmol; 250 nCi/ nmol; New England Nuclear) in 1100 μ l of 17.5 mmpotassium phosphate buffer, pH 7.5, containing 0.016% cetyltrimethylammonium bromide. Protein acylation was complete. The acyl-enzyme was precipitated with acetone as described above. The pellet was washed with 4.8 ml of cold acetone, dried *in vacuo* and dissolved in 280 μ l of 88% (v/v) formic acid. The solution was supplemented with 32 μ l of a Triton X-100 solution (3%, w/v) and 2 ml of water, and freeze-dried.

Pronase digestion of the acyl-([³⁵S]benzylpenicilloyl-)enzyme

Trypsin, subtilisin, thermolysin, *Staphylococcus aureus* proteinase V8 and Pronase were tested as proteolytic agents. Pronase, previously used for similar purposes [6,7], caused the rapid disappearance of the acyl- $([^{35}S]$ benzylpenicilloyl-)enzyme (as monitored by SDS/ polyacrylamide-gel electrophoresis) and the appearance of four major radioactive peptide fragments (as monitored by paper electrophoresis at pH 6.5, 60 V/cm for 1 h). One of these fragments (I) migrated 2 cm towards the cathode, another (II) remained at the origin of the electrophoretograms and the two others migrated 9 cm

Abbreviation used: PBP, penicillin-binding protein.

Fig. 1. Purification of the ³⁵S-labelled active-site-containing fragment (III) of the *Streptomyces* K15 DD-peptidase/PBP by chromatography on Sephadex LH20 (a) and by f.p.l.c. on a PepRPC column (b)

For details see the text. (a) — , Radioactivity. (b) ------, Radioactivity; — , A_{214} ; — , buffer B gradient. Hatched areas indicate the fragment-(III)-containing fractions.

(III) and 28 cm (IV) towards the anode. Compound (IV) was [35 S]benzylpenicilloate. Maximal yield of fragment (III) (31% of total radioactivity) was obtained by incubating 20 nmol of acyl- ([35 S]benzylpenicilloyl-)enzyme for 2 h at 37 °C with 58 µg of Pronase in 1.6 ml of 0.4% NH₄HCO₃. The solution was freeze-dried.

Isolation of the ³⁵S-labelled active-site fragment (III)

Step 1. The Pronase digest was dissolved in 100 μ l of 88 % (v/v) formic acid. After addition of 250 μ l of 95 % (v/v) ethanol, the solution was loaded on a 35 ml column of Sephadex LH20 equilibrated against an 88 % (v/v) formic acid/95 % (v/v) ethanol (1:4, v/v) mixture [8]. Elution with the same mixture yielded three major fractions (Fig. 1a). Fractions 25–30 contained fragment (II), fractions 38–47 contained fragments (I) and (III) and fractions 53–60 contained [³⁵S]benzylpenicilloate (IV).

Step 2. Fractions 38–47 were pooled and freeze-dried and the pellet was dissolved in 1 ml of 0.1% (v/v) trifluoroacetic acid. Purification of fragment (III) was achieved on a f.p.l.c. apparatus (Pharmacia, Uppsala, Sweden) equipped with a 0.5 cm × 5 cm PepRPC column, with various mixtures of buffer A (0.1% trifluoroacetic acid in water) and buffer B [0.1% trifluoroacetic acid in water/acetonitrile (3:7, v/v)]. The gradient started with 1 ml of buffer A, and then went on from 0% to 20% buffer B over 8 ml, from 20% to 40% buffer B over 12 ml and from 40% to 100% buffer B over 5 ml (flow rate 0.5 ml/min; volume of the collected fractions 460 μ l). Fractions 24–26 (Fig. 1b) were pooled and freeze-dried. The final preparation contained 0.72 nmol of purified fragment (III). Paper electrophoresis at pH 5.6 revealed the presence of a single radioactive compound. As shown below, it was, however, contaminated by free glycine.

RESULTS AND DISCUSSION

The sequence of the *N*-terminal region of the protein is shown in Fig. 2. Ambiguity was observed at some cycles following cycle 30 with the gas-phase Sequenator and following cycle 41 with the pulsed-liquid Sequenator. The enzyme preparation was very pure, valine being the only *N*-terminal residue detected.

Although the first cycle of the Edman degradation was made difficult because of the presence of large amounts of glycine, analysis of the active-site peptide fragment (III) yielded the sequence (Ser)-Thr-Gly-Ser-Thr-Xaa-(Lys), thus demonstrating that the active-site serine residue is at position 35 in the native protein. (The amount of glycine phenylthiohydantoin derivative at cycle 1 was so large that, on the basis of the radioactivity of the peptide, it was obviously a contamination. As a result of the wash-out effect, the amount of the glycine phenylthiohydantoin derivative gradually decreased during the subsequent cycles except at cycle 3.)

It has been proposed that all the penicillin-interactive active-site-serine proteins and domains, i.e. the β -lactamases of classes A, C and D, the low- M_r PBPs and the penicillin-binding domains of the high- M_r PBPs,

Fig

5 ב Identities (*) and similarities (°) with the *Streptomyces* enzyme are indicated; parentheses indicate an ambiguous residue. VD_LDD (insertion) reads The active-site serine residue is at position 35. EGK EGK form a super-family of evolutionarily related proteins [20]. One of their common features is the occurrence of the conserved tetrad Ser*-Xaa-Xaa-Lys, where Ser* is the active-site serine residue, close to the N-terminus of the proteins or domains. The alignments of Fig. 2 reveal an especially high similarity between the 20-amino-acidresidue stretch around the active-site serine residue of the Streptomyces K15 DD-peptidase/PBP (from Thr-21 to Met-40) and the corresponding regions of the penicillinbinding domain of the high- M_r PBP1B of Escherichia coli (40 % identity), the low- M_r PBP5 of E. coli (45 % identity) and the low- M_r PBP of Bacillus subtilis (50%) identity). The amino acid sequence failed to reveal the presence of a signal peptide or an N-terminal hydrophobic sequence, thus suggesting that the Streptomyces K15 enzyme, like the other known low- M_r PBPs, is probably anchored to the membrane by a C-terminal segment [21,22].

The work in Liège was supported in part by the Fonds de la Recherche Scientifique Médicale (Contract no. 3.4507.83), an Action Concertée with the Belgian Government (Convention 86/91-90), the Fonds de Recherche de la Faculté de Médecine U.Lg. and a contract with the E.E.C. (BAP-0197-B). The work in Gent was supported by the Belgian National Incentive Program of Fundamental Research in Life Sciences, initiated by the Belgian State-Prime Minister's Office-Science Policy Programming Department.
