23 Text: 7067 (Importance -> Acknowledgements)

24 **Abstract**

25 Human astroviruses (HAstVs) are a leading cause of viral childhood diarrhea that infect

26 nearly every individual during their lifetime. Although human astroviruses are highly

27 prevalent, no approved vaccine currently exists. Antibody responses appear to play an

28 important role in protection from HAstV infection, however knowledge about the

29 neutralizing epitope landscape is lacking, as only 3 neutralizing antibody epitopes have

30 previously been determined. Here, we structurally define the epitopes of 3

31 uncharacterized HAstV-neutralizing monoclonal antibodies: antibody 4B6 with X-ray

32 crystallography to 2.67 Å, and antibodies 3H4 and 3B4 simultaneously with single-

33 particle cryogenic-electron microscopy to 3.33 Å. We assess the epitope locations

34 relative to conserved regions on the capsid spike and find that while antibodies 4B6 and

35 3B4 target the upper variable loop regions of the HAstV spike protein, antibody 3H4

36 targets a novel region near the base of the spike that is more conserved. Additionally,

37 we found that all 3 antibodies bind with high affinity, and they compete with receptor

38 FcRn binding to the capsid spike. These studies inform which regions of the HAstV

39 capsid can be targeted by monoclonal antibody therapies and could aid in rational

40 vaccine design.

41

42 **Importance**

43 Human astroviruses infect nearly every child in the world, causing diarrhea, vomiting,

44 and fever. Despite the prevalence of human astroviruses, little is known about how

45 antibodies block virus infection. Here, we determined high-resolution structures of the

46 astrovirus capsid protein in complex with three virus-neutralizing antibodies. The

47 antibodies bind distinct sites on the capsid spike domain. We find that the antibodies

48 block virus attachment to human cells and prevent capsid spike interaction with the

49 human neonatal Fc receptor. These findings support the use of the human astrovirus

50 capsid spike as an antigen in a vaccine to prevent astrovirus disease.

51

52 **Introduction**

53 Human astroviruses (HAstVs) are a significant cause of childhood viral diarrhea

54 worldwide, with over 35% of children having had a HAstV infection by age 2.[1] These

55 small nonenveloped RNA viruses are typically spread by fecal-oral or salivary routes.[2,3]

56 While HAstV infections are typically self-limiting in immunocompetent people, they can

57 persist as a chronic infection in immunocompromised individuals.[4,5,6] Young children

58 and immunocompromised individuals are the populations most at risk for HAstV

59 disease, particularly in lower-income or tropical countries where higher burdens of

60 diarrheal disease and additional comorbidities may exist.[7,8] The classical HAstV clade

61 includes eight serotypes (HAstV1-8), with serotype 1 being the most prevalent

62 worldwide [9,10,11] Divergent VA and MLB clades, which may have arisen from animal

63 astroviruses, have been found to cause fatal encephalitis in immunocompromised

64 individuals, and additionally, there has been a report of central nervous system

65 involvement by classical HAstV.[12,13] Encephalitic symptoms can also be caused by

66 some animal astroviruses, such as mink and bovine astroviruses.[14,15] Notably,

67 astrovirus-associated encephalitis has been found to be endemic in mink and pig farms,

68 where animals are maintained under intensive production conditions.[16] Despite HAstV's

69   prevalence and global health impacts, there are currently no vaccines or HAstV-specific

70   therapeutics available.

71   However, the development of vaccines against HAstV seems feasible, since

72   some evidence suggests the presence of lasting HAstV immunity induced by prior

73   infection.[1] Seroprevalence to HAstV in adults is very high (>90%)[17,18], and HAstV

74   disease is rarer in adults than in children.[19] Additional studies have supported that the

75   presence of anti-HAstV antibodies may help to protect from severe HAstV disease,[3] and

76   one case study showed improvement in a patient with chronic HAstV disease after

77   immunoglobulin therapy. However, the mechanism of how antibodies neutralize HAstV

78   is not well understood, in part due to a lack of knowledge surrounding how antibodies

79   interact with the viral capsid, and which parts of the exposed viral capsid are critical for

80   its function.

81   The HAstV virion consists of a small proteinaceous icosahedral capsid roughly

82   ~40 nm in diameter, which shelters a ~7 kb single-stranded positive sense

83   polyadenylated RNA genome. The immature capsid is made up of 180 units of capsid

84   protein originating from open reading frame 2 (ORF2), and displays a T=3 symmetry.

85   The capsid protein is initially expressed as a 90 kDa protein (VP90), which undergoes

86   an intracellular caspase cleavage that is important for viral release from the cell,

87   resulting in a ~70 kDa (VP70) protein after the loss of its C-terminal acidic domain.[20,21]

88   In this state, the virus remains immature and must undergo further extracellular

89   protease cleavage(s) to reach its mature infectious form. The exact extracellular

90   protease used *in vivo* for this cleavage event is unknown, but *in vitro* cleavage with

91   trypsin results in a 10^5 fold increase in infectivity.[22] This extracellular protease cleavage

92 event cleaves VP70 into the core domain (VP34), and spike domain (VP25/VP27), and

93 additionally removes 60 of the initial 90 dimeric spikes along 5-fold symmetry axes,

94 resulting in 30 dimeric spikes (VP27) remaining on the mature capsid along the 2-fold

95 symmetry axes.[23,24] The spike domain is known to be important for attachment and

96 entry of the virus, and antibodies that target the spike domain have been found to

97 neutralize HAstV in cell culture, whereas antibodies that target the core domain have

98 not been reported to neutralize HAstV.[25,26] Recently, two preprint articles reported the

99 identification of the neonatal Fc receptor (FcRn) as an important host receptor for

100 human astrovirus entry, and FcRn was found to bind the HAstV capsid spike.[27,28]

101 However, information about which regions of the spike are important for this interaction

102 and how antibodies may interfere with this function remains mostly unexplored.

103   Only three HAstV-neutralizing antibody epitopes have been structurally defined,

104 revealing two neutralizing antigenic sites on the HAstV spike, since two of the

105 neutralizing antibodies (3E8, PL-2) have overlapping epitopes.[29,30] Both neutralizing

106 epitope regions were located around a conserved putative receptor binding site on the

107 surface of the HAstV spike, known as the "P-site," and these antibodies were

108 additionally shown to block spike attachment to cells.[29] Whether these antibodies

109 prevent FcRn binding or some other host factor interaction remains unknown.

110 Furthermore, whether additional neutralizing antigenic sites exist on the HAstV spike

111 remains unknown. Here, we structurally define three novel neutralizing antibody

112 epitopes, assess their epitope location relative to conserved regions of the HAstV spike,

113 and provide evidence supporting their mechanism of HAstV neutralization.

114

Materials and Methods:

Cells and viruses.

Caco-2 cells, clone C2Bbe1 (ATCC), were propagated in high-glucose Dulbecco's

modified Eagle's medium (DMEM-HG) (Sigma) supplemented with nonessential amino

acids (Gibco) and 15% fetal bovine serum (FBS) (Cansera) in a 10% CO_2 atmosphere

at 37°C. HAstV serotypes 1 and 2 have been described previously.[26] All viral strains

were activated with trypsin and grown as described before.[31]

Expression and purification of recombinant HAstV1 and HAstV2 capsid spike proteins:

Recombinant HAstV1 and HAstV2 spikes were produced as described previously.[32,31]

Briefly, cDNA corresponding to HAstV1 capsid protein residues 429 to 645 (GenBank:

AAC34717.1) or HAstV2 Oxford strain capsid protein residues 429 to 644 (GenBank:

KY964327.1) were cloned into pET52B with a C-terminal thrombin cleavage site and a

10-histidine purification tag sequence. Recombinant spikes were expressed in

Escherichia coli BL21(DE3) and purified from soluble lysates by HisTrap metal-affinity

chromatography. Purified HAstV spikes were dialyzed into TBS (10 mM Tris pH 8.0 and

150 mM NaCl).

Expression and purification of recombinant monoclonal antibody Fabs 3B4, 3H4, and

4B6:

The protein-coding sequence of antibodies 3H4, 3B4, and 4B6 heavy and light chains

were determined as described previously.[33] The protein-coding sequences of 3H4, 3B4,

and 4B6 light chain and the 3H4, 3B4, and 4B6 heavy chain antigen-binding fragment

138   (Fab) were cloned into separate pCMV plasmids in-frame with an N-terminal human

139   IgG1 signal sequence. The Fab heavy chains were cloned in-frame with a C-terminal

140   thrombin-cleavable double StrepTagII affinity tag. A total of 120 µg of heavy chain

141   plasmid and light chain plasmid combined were added to 8 x 10^7 CHO-S cells in an OC-

142   400 cuvette (MaxCyte) and were electroporated. CHO-S cells were resuspended in CD-

143   OptiCHO media (Gibco: #12681029) and fed CHO feed (CHO CD EfficientFeed A

144   (Gibco: #A1023401) supplemented with 7 mM L-glutamine, 5.5% glucose, and 23.4 g/L

145   yeastolate) every 24 hours. CHO-S cells were given a final concentration of 1 mM

146   sodium butyrate and maintained at 32 °C, 8 % CO_2, 85% humidity, 135 rpm, 24 hours

147   after electroporation for 8-10 days. CHO-S cells were centrifuged, and the resulting

148   supernatants were given 1X protease inhibitor cocktail (Millipore 539137), BioLock (Iba

149   Lifesciences 2-0205-050) to block free biotin in the media, and Strep Wash Buffer (50

150   mM Tris pH 7.4, 150 mM NaCl, 1mM EDTA), and were 0.22 µm filtered. Samples were

151   loaded onto a regenerated StrepTrap HP 5 ml column (Cytiva), washed with Strep

152   Wash Buffer, and eluted with an increasing linear gradient of Strep Elution Buffer (Strep

153   Wash Buffer + 2.5 mM desthiobiotin).

154

155   Expression and purification of recombinant monoclonal antibody scFv 3B4, 3H4, 4B6

156   Codon-optimized cDNA encoding the 4B6 variable heavy chain and variable light chain

157   connected by a GGS(GGGGS)$_3$ linker, were cloned into a derivative pCDNA3.1 vector

158   in frame with an N-terminal human IgG1 signal sequence and a C-terminal thrombin-

159   cleavable double StrepTagII affinity tag. A total of 120 µg of this plasmid was added to 8

160   x 10^7 CHO-S cells and was electroporated. scFv 4B6 expression and purification were

161   performed as described above for Fabs. Purified scFv was dialyzed into TBS. Synthetic

162   genes for scFv 3H4 and 3B4 constructs were designed with the light and heavy chain

163   variable domains connected by a GGS(GGGGS)$_3$ linker and flanking BgIII and NheI

164   restriction sites. The gene was codon optimized for *Drosophila melanogaster* and

165   ordered from Integrated DNA Technologies. The gene was cloned into a pMT_puro_BiP

166   vector via restriction digest in frame with an N-terminal BiP secretion signal and a C-

167   terminal thrombin cleavable double StrepII affinity tag in the vector. pMT-puro_BiP

168   vectors containing scFv 3H4 and scFv 3B4 were used to make stably transfected

169   Schneider 2 (S2) cells as described previously.[29] Expression and purification was

170   performed as described previously. [29]

171

172   <u>Expression and purification of recombinant neonatal Fc receptor (FcRn):</u>

173   Codon-optimized cDNA encoding the ectodomain of the FCGRT gene (UniProt:

174   P55899, Met1-Ser297) or the β-2-Microglobulin gene (UniProt: P61769, Met1-Met119)

175   were cloned separately into a derivative pCDNA3.1 vector.[34] The FCGRT construct also

176   contained a C-terminal thrombin-cleavable double StrepTagII affinity tag. A total of 40

177   μg of FCGRT plasmid and 80 μg of β-2-Microglobulin plasmid were added to 8 x 10^7

178   CHO-S cells and electroporated. CHO cell expression was performed as described

179   above. The supernatant was loaded onto a StrepTrap XT affinity column (Cytiva),

180   washed with Strep Wash Buffer, and eluted with Elution Buffer (Strep Wash containing

181   50mM biotin). Purified FcRn was dialyzed into TBS.

182

183   <u>Binding assays of HAstV in the presence of neutralizing antibodies</u>

184   Serial 1:5 dilutions of the ascitic fluids for 3B4, 3H4, or for 4B6, were pre-incubated with

185   infectious, purified HAstV1 or HAstV2 particles, respectively (multiplicity of infection

186   [MOI] = 30), for 1 h at room temperature. Caco-2 cell monolayers grown in 48-well

187   plates were washed once with PBS, and then blocking solution (1% BSA in PBS) was

188   added for 45 min at room temperature, followed by a 15 min incubation on ice. The cells

189   were then washed once with ice-cold PBS and incubated with the virus-antibody

190   complex for 1 h on ice. MAb 2D9, which neutralizes HAstV8, was used as a negative

191   control. The unbound virus was washed three times with cold PBS, and the total RNA

192   was extracted with TRIzol Reagent (Invitrogen) according to the manufacturer's

193   instructions. Viral RNA or cellular 18S RNA was reverse transcribed using MMLV

194   reverse transcriptase (Invitrogen). RT-qPCR was performed with the premixed reagent

195   Real Q Plus Master Mix Green (Amplicon), and the PCR was carried out in an ABI

196   Prism 7500 Detection System (Applied Biosystems). The primers used to detect HAstV1

197   RNA were Fwd 5' -ATGAATTATTTTGATACTGAAGAAAATTACTTGGAA - 3' and Rev

198   5' - CTGAAGTACTTTGGTACCTATTTCTTAAGAAAG - 3'. For detection of HAstV2

199   RNA were Fwd 5' -ATGAATTATTTTGATACTGAAGAAAGTTATTTGGAA - 3' and Rev

200   5' - CTGAAGTACTGTGGTACCTATTTCTTAAGAAAG - 3'. For normalization, 18S

201   ribosomal cellular RNA was amplified and quantified using forward primer 5'-

202   CGAAAGCATTTGCCAAGAAT - 3' and reverse primer 5' -

203   GCATCGTTTATGGTCGGAAC - 3'.

204

205   <u>Assay to determine if the neutralizing antibodies detach HAstV particles bound to cells:</u>

206   Confluent Caco-2 cell monolayers in 48-well plates were blocked with 1% BSA in PBS

207   for 45 min at room temperature followed by a 15 min incubation on ice. Purified HAstV-1

208   or HAstV-2 particles were added at an MOI of 30 and then incubated for 1 h on ice to

209   allow the binding of the virus to the cell surface. The unbound virus was subsequently

210   removed by washing three times with cold PBS. Serial 1:5 dilutions of the indicated

211   ascitic fluids of either 3B4 or 3H4 for HAstV1, or 4B6 for HAstV2 were added to the cells

212   and then incubated for 1 h on ice. After this incubation, the antibody and unbound virus

213   were removed with cold PBS, and RNA extraction and RT-qPCR quantification were

214   performed as described above. MAb 2D9, which neutralizes HAstV8, was used as a

215   negative control.

216

217   <u>X-ray crystallography structure determination of HAstV2 spike/scFv 4B6 complex:</u>

218   Thrombin digestion was used to remove the Histidine-tag from HAstV2 spike and to

219   remove the StrepII tag from scFv 4B6 (10 U thrombin/mg of protein incubated at 4 °C on

220   a rotating plane overnight). Digestion of StrepII tag from scFv 4B6 and Histidine-tag

221   from HAstV2 spike was confirmed by SDS-PAGE where no visually detectable

222   undigested product was observed. HAstV2 spike was incubated with 2X molar excess

223   scFv 4B6 per spike monomer and the resulting complex was purified by size-exclusion

224   chromatography on a Superdex 75 10/300 GL column. Fractions corresponding to

225   HAstV2 spike/scFv 4B6 complex were determined by peak comparison with gel filtration

226   standards (peak elution volume corresponding to ~100 kDa) and SDS-PAGE analysis.

227   Fractions of purified HAstV2 spike/scFv 4B6 complex were pooled and concentrated to

228   5 mg/ml in TBS pH 8.5. HAstV2-spike/scFv 4B6 protein crystals were formed in 2 μl

229   drops containing a 1:1 ratio of protein solution to well solution consisting of 0.1 M Tris-

230   HCl pH 8.5, and 0.74 M sodium citrate pH 5.5, using hanging drop vapor diffusion at 22

231   °C. A single crystal was transferred into a cryoprotectant solution consisting of well

232   solution and 18% glycerol, and was then flash-frozen into liquid nitrogen. The Advanced

233   Photon Source synchrotron beamline 23-ID-D was used to collect a diffraction dataset

234   with wavelength 1.0332 Å at cryogenic temperatures. The dataset was processed and

235   scaled using DIALS (ccp4i2)[35] with a resolution cutoff of 2.67 Å based upon $CC_{1/2}$ and

236   I/σI statistics. A trimmed model of HAstV2 spike (PDB: 3QSQ) and a trimmed model of

237   scFv 4B6 generated by SWISS-model using tremelimumab Fab as a template (PDB:

238   5GGU) was used for molecular replacement with Phaser. The structure was then

239   manually modeled using Coot[36] and refined in Phenix.[37] The final model was deposited

240   into the Protein Data bank (PDB 9CN2).

241

242   <u>Single-particle CryoEM structure determination of HAstV1 spike/Fab 3B4/Fab 3H4</u>

243   <u>complex:</u>

244   Thrombin digestion was used to remove the Histidine-tag from HAstV1 spike and

245   remove the StrepII tags from Fab 3H4 and Fab 3B4 as described above. HAstV1 spike

246   was complexed with 2X molar excess Fab 3B4 and the resulting complex was purified

247   by SEC on Superdex 200 10/300 GL column. Fractions corresponding to the HAstV1

248   spike/Fab 3B4 complex were determined by peak comparison with molecular weight

249   standards (peak elution volume corresponding to ~100 kDa) and SDS-PAGE analysis.

250   These fractions were pooled, and the resulting complex was then mixed with 1.5X molar

251   excess Fab 3H4 and purified by SEC on a Superdex 200 10/300 GL column. Fractions

252 corresponding to the full HAstV1 spike/Fab 3B4/Fab 3H4 complex were determined by

253 peak comparison with gel filtration standards (peak elution volume corresponding to

254 ~200 kDa) and SDS-PAGE analysis. Fractions of purified HAstV1 spike/Fab 3H4/Fab

255 3B4 complex were pooled and concentrated to 0.86 mg/ml in 10 mM Tris pH 7.0 and

256 150 mM NaCl. 3 µl of protein complex was mixed with 0.5 µl of 25 µM lauryl maltose

257 neopentyl glycol (LMNG) detergent to remove orientation bias and was then deposited

258 onto glow discharged UltrAuFoil R.12/1.3 gold grids 400 mesh, blotted using a

259 ThermoFisher Scientific (TFS) Vitrobot Mark IV at 4 °C and 100% humidity, and then

260 plunge frozen into liquid ethane. Grids were screened at UCSC's Biomolecular CryoEM

261 facility using a TFS Glacios 200 kV microscope coupled to a Gatan K2 Summit direct

262 detector. The top-selected grids were then sent to the Pacific Northwest Center for

263 Cryo-EM (PNCC #160263) for data collection on a TFS Krios G3i microscope coupled

264 to a Gatan K3 Biocontinuum Gif.

265   7,235 movies containing 60 frames each were collected using a pixel size of

266 0.415 Å/pixel in super-resolution mode (105,000 x) and an electron dose of 32.26 e/A^2.

267 Movies were preprocessed (motion correction and CTF estimation) in CryoSPARC

268 v4.3.2.[38] Initial particle identification was performed using an unbiased blob picker,

269 resulting in 4,132,753 particles, further extracted in a box size 686 pixels. After multiple

270 rounds of 2D classification, 55 top-selected classes containing 214,273 particles

271 underwent the *Ab-initio* reconstruction.

272 3 selected volumes were generated and then 3D-classified and further refined. The

273 best-representing 3D class was used to create 2D references for a round of template

274 picking. 2,718,470 particles were extracted with a box size 686 pixels, and then

275 underwent on the similar previously established workflow. The top 72 classes containing

276 262,500 particles were used in a new *Ab-initio* reconstruction. The 2 generated classes

277 were 3D-classified, where one class resulted in an overall gold-standard resolution

278 (FSC$_{0.143}$) of 5.70 Å and containing 138,147 particles. This volume was selected and

279 underwent non-uniform refinement, and further non-uniform refinement using a mask

280 encompassing the entire particle, resulting in a 3D reconstructed volume at 3.74 Å.

281 Unused particles were added from the previous 2D classification, and all particles

282 received local CTF refinement, resulting in a volume of 3.43 Å and 163,237 particles

283 after non-uniform refinement. Additional rounds of local CTF refinement were performed

284 and a mask in which the constant domains of the Fab were removed was used to align

285 particles in local refinement, in order to improve the tridimensional alignment and local

286 resolution of the epitope regions, resulting in the final reconstructed map at 3.33 Å

287 overall resolution. The sharpened map (B factor -112 Å^2) was opened in ChimeraX

288 (version 1.5.0) and starting models of the HAstV1 spike (PDB: 5EWO) and AlphaFold 3

289 models of Fabs 3H4 and 3B4 were fitted into the volume. Since the Fab constant

290 domain volume density was poor, the constant domains were removed from the models.

291 The initial model representing the complex was opened in Coot (version 0.9.1) and

292 underwent several rounds of manual refinement and global real-space refinement and

293 was validated using Phenix and MolProbity. The final reconstructed map was deposited

294 in the Electron Microscopy Data Bank (EMD-45427) and the final model was deposited

295 into the Protein Data Bank (PDB: 9CBN). The raw data was made available in EMPIAR

296 DOI: https://doi.org/10.6019/EMPIAR-12182.

297

298   <u>Biolayer interferometry K_D determination of neutralizing antibodies 3B4, 3H4, and 4B6:</u>

299   Biolayer interferometry assays on an Octet RED384 instrument were used to determine

300   binding affinity dissociation constants (K_D). Assays were performed in Octet Kinetics

301   Buffer (PBS pH 7.4 + 0.1% BSA + 0.02% Tween 20) for Fabs 3H4 and 3B4, or Octet

302   Kinetics Buffer + biocytin (PBS pH 7.4 + 0.1% BSA + 0.02% Tween 20 + 50 µM

303   biocytin) for Fab 4B6. For assays with Fabs 3H4 and 3B4, pre-equilibrated Anti-Penta-

304   His (HIS1K) biosensor tips were dipped into Octet Kinetics Buffer for 60 seconds for an

305   initial baseline reading, dipped into 0.5 µg/ml histidine-tagged HAstV1 spike diluted in

306   Octet Kinetics Buffer for 180 seconds to load the sensor tip, and dipped into Octet

307   Kinetics Buffer for 60 seconds for a second baseline reading. Biosensors were then

308   dipped into 4-point serial dilutions of Fab in Octet Kinetics Buffer, consisting of 2.5 nM, 5

309   nM, 10 nM, and 20 nM for Fab 3H4, and 20 nM, 40 nM, 80 nM, 160 nM for Fab 3B4.

310   This association step was run for 180 seconds, and then biosensors were dipped into

311   Octet Kinetics Buffer to measure dissociation for a total of 600 seconds. For assays with

312   Fab 4B6, pre-equilibrated Anti-Penta-His (HIS1K) biosensor tips were dipped into Octet

313   Kinetics Buffer + biocytin for 60 seconds for an initial baseline reading, dipped into 0.5

314   µg/ml histidine-tagged HAstV2 spike diluted in Octet Kinetics Buffer + biocytin for 180

315   seconds to load the sensor tip, and dipped into Octet Kinetics Buffer for 60 seconds for

316   a second baseline reading. Biosensors were then dipped into a 4-point serial dilutions of

317   Fab 4B6 in Octet Kinetics Buffer, consisting of 25 nM, 50 nM, 100 nM, and 200 nM. This

318   association step was run for 60 seconds, and then biosensors were dipped into Octet

319   Kinetics Buffer to measure dissociation for a total of 60 seconds. These shorter

320   association and dissociation steps were chosen due to the lower affinity of the Fab 4B6.

321 Kinetics data was processed the same way for all Fabs in the Data Analysis HT

322 software. The baseline step was used to align traces and apply inter-step correction. A

323 reference sample well containing only a spike-loaded biosensor dipped into no analyte

324 (Fab) was subtracted. Savitzky-Golay filtering was used on the traces. For curve fitting,

325 a 1:1 model was globally applied to the dilution series, and fit was evaluated based on

326 R^2 and χ^2 values and visual inspection. Average K_D values are reported as the average

327 of the three replicates.

328

329 <u>Biolayer interferometry competition assay of Fabs versus FcRn for HAstV spike:</u>

330 Biolayer interferometry competition assays were performed with an Octet RED384. Pre-

331 equilibrated Streptavidin (SA) biosensors tips were dipped into Octet Kinetics Buffer for

332 60 seconds for an initial baseline reading. For Fabs 3H4 and 3B4, 0.5 µg/ml of

333 biotinylated HAstV1 spike was loaded onto SA biosensors tips for 300 seconds, and

334 dipped into Octet Kinetics Buffer for 30 seconds for a baseline reading. Biosensors were

335 then dipped into either 150 nM Fab 3H4 or 250 nM Fab 3B4 in Octet Kinetics Buffer for

336 600 seconds to ensure saturation of all spike binding sites, dipped into Octet Kinetics

337 Buffer for 30 seconds as a baseline reading, and then dipped into 2 µM FcRn in Octet

338 Kinetics Buffer for 300 seconds. For Fab 4B6, the assay was performed with the same

339 methods, but 0.5 µg/ml biotinylated HAstV2 spike was used during the antigen loading

340 step, Octet Kinetics buffer + biocytin was used for all assay steps after antigen loading,

341 250 nM Fab 4B6 was using during the antibody association step, and due to its lower

342 affinity 250 nM of Fab 4B6 was also included in the baseline step after antibody

343 association and in the FcRn sample to maintain saturation of Fab 4B6 on spike. All

344   assays contained additional controls such as a sample in which the primary Fab was

345   dipped into the same concentration of self Fab instead of FcRn to ensure that saturation

346   was achieved, and also a control in which FcRn was bound to the HAstV spike in the

347   absence of any Fab in the first association. All assays were performed in duplicate.

348   Competition data was processed the same way for all Fabs in the Data Analysis HT

349   software in the Epitope Binning module. A matrix representing competition was

350   generated using the shift between the last 10% average of the signal from the second

351   association and the last 10% average of the signal from the primary association step.

352   The signal from the control in which primary Fab was dipped into self Fab for the

353   second association was subtracted in the matrix row (the shift values from all samples

354   containing the respective Fab), such that full competition is represented by "0." The

355   signal from the control sample in which FcRn was associated to HAstV spike with no

356   Fab in the primary association was used to normalize in the matrix column (the shift

357   values from samples with FcRn binding in the secondary association step) such that

358   maximum FcRn binding with no competition represents "1." This normalization is done

359   separately for Fab 4B6 vs Fab 3H4 and 3B4 assays given the different spike serotypes

360   to which FcRn is associated to, but is displayed in the same table. Fabs were

361   considered to compete with FcRn if FcRn binding in the presence of Fab was reduced

362   by 50% or more (a value of 0.5 or lower). The values shown are an average of duplicate

363   assays.

364

365   scFv 3B4, scFv 3H4, and 4B6 neutralization assays:

366   The indicated concentration of antibody or scFv was preincubated with HAstV1 (for

367   scFv 3H4, scFv 3B4 and mAb 3B4) or HAstV2 (for scFv 4B6) at an MOI of 0.02, for 1 h

368   at room temperature. The virus-antibody mixture was then added to confluent Caco-2

369   cell monolayers grown in 96-well plates and incubated for 1 h at 37°C. After this time,

370   the cells were washed three times with minimum essential medium (MEM) without

371   serum, and the infection was left to proceed for 18 h at 37°C. Infected cells were

372   detected by an immunoperoxidase focus-forming assay, as described previously.[26]

373

374   Data availability

375   Coordinates and structure factors for the HAstV2 spike/scFv 4B6 complex structure was

376   deposited in the Protein Data Bank (www.rcsb.org) under accession code 9CN2. For

377   the HAstV1 spike/Fab 3B4/Fab 3H4 complex structure, the final reconstructed map was

378   deposited in the Electron Microscopy Data Bank (EMD-45427) and the final model was

379   deposited into the Protein Data Bank under accession code 9CBN. The raw data was

380   made available in EMPIAR at https://doi.org/10.6019/EMPIAR-12182.

381

382   **Results:**

383   HAstV-neutralizing antibodies 3B4, 3H4, and 4B6 bind with high affinity to the HAstV

384   spike.

385   We previously generated a panel of IgG1 monoclonal antibodies (mAbs), three of which

386   were found to neutralize either HAstV1 (mAbs 3B4 and 3H4) or HAstV2 (mAb 4B6) in

387   Caco-2 cells, the gold standard cell line used for HAstV propagation and infectivity

388   studies. Here, we generated recombinant antigen-binding fragments (Fabs) of these

389   HAstV-neutralizing antibodies to remove the avidity effects of a full bivalent mAb given

390   the homodimeric nature of their target, the HAstV capsid spike domain. To determine

391   binding affinities, biosensors loaded with HAstV spike were dipped into serial dilutions of

392   Fabs. All three Fabs bind the corresponding HAstV spike with high affinities, with

393   dissociation constants (K_Ds) in the mid-low nanomolar range (Table 1, Supp. Fig. 1).

394   These results indicate that immunization with recombinant HAstV spikes are able to

395   induce high affinity HAstV-neutralizing antibodies in mice. Interestingly, Fab 4B6 has the

396   lowest affinity of the three antibodies, yet has the most potent neutralizing activity.[26]

397   This observation may indicate that other factors besides affinity, such as the location of

398   the antibody binding site or avidity, may influence HAstV neutralization, or this result

399   could be related to serotype difference.

400

401   <u>HAstV-neutralizing antibodies 3B4, 3H4, and 4B6 block attachment of HAstV to Caco-2</u>

402   <u>cells.</u>

403   To further investigate the mechanism of antibody neutralization, we tested whether

404   mAbs 3B4, 3H4, or 4B6 could block attachment of HAstV to Caco-2 cells, and whether

405   these antibodies could detach the virus which was already bound to cells. Caco-2

406   monolayers were incubated with HAstV-antibody complexes, or HAstV alone. Unbound

407   virus was washed away and the bound virus was quantified using RT-qPCR. We found

408   that all three antibodies were able to block virus attachment to cells in a dose-

409   dependent manner compared to a negative control antibody (Fig. 1). Interestingly, only

410   4B6 was able to detach pre-bound virus (Fig. 2). This detachment does not appear to

411   be a function of a high affinity displacement, as 4B6 had the lowest affinity of the three

412   antibodies (Table 1). This could indicate that other factors, such as the binding location,

413   may play a role in an antibody's ability to detach virus. It is also possible that the

414   serotype affects the ability of the virus to be displaced, as 3H4 and 3B4 neutralize

415   serotype 1, while 4B6 neutralizes serotype 2. The inability of 3H4 and 3B4 to detach

416   virus is also in contrast to previously characterized antibodies 2D9 and 3E8 which

417   neutralize serotype 8 and were able to detach bound virus.[26]

418

419   <u>HAstV-neutralizing antibodies 3B4, 3H4, and 4B6 compete with FcRn binding to HAstV</u>

420   <u>spike.</u>

421   With the recent discovery of FcRn as a critical receptor for HAstV infection, we

422   investigated whether the HAstV-neutralizing antibodies 3B4, 3H4, and 4B6 could

423   compete with FcRn's ability to bind to the HAstV spike. Either HAstV1 or HAstV2 spikes

424   were loaded onto biosensors and then dipped into saturating levels of Fab 3H4, 3B4, or

425   4B6. The biosensors were then dipped into FcRn and these binding shifts were

426   compared to the binding shifts of FcRn to spike-loaded biosensors in the absence of

427   Fab. From this assay, we determined that Fabs 3H4 and 4B6 fully block FcRn binding

428   (Table 2), suggesting that these Fabs either directly or sterically block FcRn's ability to

429   bind the spike protein. Fab 3B4 does not appear to fully block FcRn binding, but

430   reduces FcRn binding to 40% of the control. Given that 3B4 is still efficient at

431   neutralizing HAstV1, Fab 3B4 may have an alternative mechanism of neutralizing

432   HAstV, such as blocking the interaction of another putative receptor, or the full-length

433   mAb may be necessary for full steric hindrance of the FcRn interaction with HAstV1

434   spike. These data suggest that one mechanism of antibody neutralization may be by

435   blocking the FcRn interaction with the HAstV spike.

436

437   <u>HAstV2-neutralizing antibody binds to a distinct epitope on the upper loops of HAstV2</u>

438   <u>spike.</u>

439   Currently, the epitopes for only three HAstV-neutralizing monoclonal antibodies have

440   been structurally defined, which revealed two immunogenic sites on the spike.[29,30]

441   Subsequently, we sought to characterize three additional neutralizing antibodies, 3B4,

442   3H4, and 4B6, to determine if other immunogenic sites on the HAstV spike exist.

443   Previous escape mutation studies identified two adjacent amino acid changes in the

444   HAstV2 spike, D564E and N565D, which allowed HAstV2 to overcome the neutralizing

445   activity of antibody 4B6.[26] However, the epitope of mAb 4B6 has not been structurally

446   defined. To visualize where neutralizing antibody 4B6 binds to the HAstV spike, we

447   solved the crystal structure of the recombinant single-chain variable fragment (scFv)

448   4B6 in complex with the HAstV2 spike to 2.67 Å resolution (Fig. 3). This structure

449   revealed that 4B6 binds to a novel 694 $Å^2$ quaternary epitope at the top of the spike.

450   Each chain of 4B6 interacts predominantly with the long loop 3 from the opposing

451   protomer, with some residues in the CDR-H3 loop of the heavy chain interacting with

452   both protomers (Fig. 3C,D). All 3 CDR's in 4B6 heavy chain interact with the spike, but

453   in the light chain, only CDR-L1 and CDR-L3 interact. Antibody 4B6 forms a network of 8

454   hydrogen bonds with spike residues 563-567 at the very tip of loop 3, which interact with

455   both light chain CDR L3 residues Y226-Y231 and heavy chain CDR H3 residues D102

456   and T99 (Fig. 3C). This hydrogen bond network consists of a mix of side-chain and

457   backbone interactions for both the antibody and spike. This data correlates with the two

458   residues D564 and N565 on loop 3 that were previously identified as locations for

459   escape mutations to antibody 4B6—the mutation of these two residues would disrupt at

460   least 2 hydrogen bond interactions, which may explain how these escape mutations

461   disrupt 4B6 neutralization of HAstV (Fig. 3B). The HAstV spike loop 3, which 4B6

462   primarily targets, is highly variable across strains of HAstV, which may indicate that this

463   location is particularly immunogenic and frequently targeted by antibodies, creating

464   selective pressure for the virus to mutate this region.

465

466   <u>HAstV1-neutralizing antibody 3H4 binds to a novel epitope near the base of the spike,</u>

467   <u>and HAstV1-neutralizing antibody 3B4 binds the top dimer interface in a unique</u>

468   <u>asymmetric way.</u>

469   Previous escape mutation studies revealed a single point mutation K504E (for 3H4) or

470   S560P (for 3B4) in the HAstV1 spike that allowed the virus to escape the neutralizing

471   effects of antibody 3H4 or 3B4. To define the full epitopes of antibodies 3H4 and 3B4,

472   we solved the structure of both Fabs 3H4 and 3B4 in complex with the HAstV1 spike to

473   3.33 Å resolution using single-particle cryoEM (Fig. 4A,B, Supp. Fig. 2). This structure

474   reveals two novel epitopes, with a single Fab 3B4 bound to the top of the spike dimer

475   interface, and two Fab 3H4 bound to the bottom sides of the spike dimer (Fig. 4A,B).

476   Antibody 3B4 spans a 1039 Å^2 quaternary epitope across the top dimer interface, with

477   more of the epitope located on one protomer than the other (Fig. 4A,E). Based on the

478   structure, as well as the retention volume of the complex in solution on a size-exclusion

479   chromatography column, only one Fab 3B4 can bind the spike homodimer at a time,

480 which represents the first antibody of its kind to be discovered for HAstV, as all other

481 previously characterized antibodies can bind symmetrically with one antibody binding

482 site per protomer. Antibody 3B4 targets the majority of loop 3 on one monomer closer to

483 the base of the loop, and the side of loop 3 on the other monomer. Although 3B4 targets

484 a similar structural region on HAstV1 spike as that of 4B6 on HAstV2 spike, it interacts

485 with unique residues focused more on the center of the dimer interface, while 4B6 is

486 targeted more outward towards the tips of loop 3. All six of 3B4 CDR loops interact with

487 the spike, forming a hydrogen bond network primarily between spike residues G573-

488 T577, and 3B4 residues S30-N32 on CDR-L1 (Fig. 4C). Q53 and S50 from CDR-L2

489 also contribute several hydrogen bonds, with Q53 making two hydrogen bonds with

490 T613 and N614. On the heavy chain, the majority of the hydrogen bonds are contributed

491 by CDR-H1 residues T28 and T30, which target T562 and S560 on the spike. Although

492 a single point mutation of S560P in the spike sequence confers resistance to antibody

493 3B4 neutralization, this mutation actually changes two distinct sites of interaction with

494 the heavy chain of 3B4, given the close locations of each S560 to each other on the

495 dimer interface (Fig. 4C,E). This could suggest that single point mutations offer higher

496 resistance to dimer interface antibodies in comparison to antibodies that bind both

497 protomers. Despite both 4B6 and 3B4 targeting loop 3, 3B4 targets residues that are

498 more conserved.

499   Fab 3H4 binds to a novel 676 Å^2 epitope near the base of the spike which is

500 distinct from any other known HAstV-neutralizing antibody epitopes, as all previously

501 solved spike-antibody structures target the top or upper sides of the spike dimer (Fig.

502 4A,B). The 3H4 epitope interaction is facilitated almost entirely by the heavy chain

503   alone, with only W93 from CDR L1 and Y34 CDR L3 from the light chain making any

504   contact with the spike (Fig. 4D,E). Antibody 3H4 mostly targets the upper portion of the

505   spike loop 2 with all 3 heavy chain CDR loops. Two salt bridges formed between K514

506   on spike and D101 on CDR-H3, and K504 with E98 on CDR-H3 (Fig. 4D). These lysine

507   residues also form hydrogen bonds and cation-pi interactions with Fab 3H4. Notably,

508   the salt bridge interaction by K504 appears critical to the ability of 3H4 to bind to spike

509   as the mutation of K504 to a negatively-charged glutamic acid disrupts 3H4

510   neutralization of HAstV1.[26] Antibody 3H4 also targets a region of much higher

511   conservation than that of the other antibodies, with over 70% of the interacting spike

512   residues being semi-conserved or higher amongst the 8 HAstV serotypes. Despite the

513   majority of residues being conserved, K504, which is critical to 3H4 neutralization, is

514   highly variable among serotypes, which likely accounts for the 3H4 serotype

515   specificity.[26]

516

517   <u>3B4, 3H4, and 4B6 scFv neutralize HAstV.</u>

518   Antibody 3H4 reveals a particularly interesting epitope location, as the full-length

519   antibody would likely clash with the icosahedral core of the HAstV capsid, suggesting

520   that this antibody may contort the spike dimer in some way. Since 3H4 binds so

521   distantly from other structurally determined neutralizing antibody epitopes and yet is still

522   shown to block FcRn receptor binding, we hypothesized that 3H4 may neutralize HAstV

523   by steric hinderance with its constant regions and contortion of the spike, rather than the

524   direct blocking of an important functional site on the spike. We tested whether scFv

525   3H4, scFv 3B4, and scFv 4B6 which lack antibody constant domains, could still

526   neutralize HAstV1 (scFv 3H4 and scFv 3B4) or HAstV2 (scFv 4B6). HAstV1 was

527   preincubated with serial dilutions of scFv 3H4, scFv 3B4, or mAb 3B4 as a control, or

528   HAstV2 with scFv 4B6, and was incubated on a Caco-2 cell monolayer, and viral

529   infection was measured by an immunoperoxidase focus-forming assay. We found that

530   both the scFv 3H4, 3B4, and 4B6 are still able to neutralize HAstV and do so to a similar

531   degree, but are not as effective at neutralization as full-length mAb (Fig. 5B), indicating

532   that steric hinderance and/or avidity have a role in the ability of these antibodies to

533   neutralize virus. 4B6 appears to be the most affective at neutralization despite its lower

534   affinity, however, this could also be a function of it neutralizing a different serotype than

535   3H4 and 3B4.

536

537   AlphaFold3 prediction accuracy.

538   As predictive protein structural software advances, we sought to assess how accurately

539   the recent release of AlphaFold 3 (AF3) could predict antibody-antigen interactions.[39]

540   We compared the crystal structure of scFv 4B6 and HAstV2 spike with that of its

541   AlphaFold prediction, and found that not only was the antibody placed correctly, but

542   even the side chain interactions were highly accurate (Supp. Fig. 3A). However, on a

543   macroscopic scale, the dimer interfaces appear to be slightly misaligned, causing the

544   other protomer alignment and subsequent interacting residues to be slightly misaligned

545   (Supp. Fig. 3D,E), though the local side chain orientations still appear to be highly

546   accurate. AF3 was confident in its prediction, with pTM of 0.88 and ipTM of 0.86. The

547   overall accuracy of the AF3 model is quite high, with a TM-score of 0.97 (TM value of

548   1=identical match) when the AF3 model is aligned to the crystal structure. This is a

549   substantial improvement from the AlphaFold 2 (AF2) prediction, which did not place

550   scFv 4B6 in the correct general placement, let alone correct side chain orientations

551   (Supp. Fig 3A). We additionally compared the AF3 model of Fab 3H4 and Fab 3B4 with

552   our solved cryoEM structure. The AF3 model of Fab 3H4 bound to HAstV1 spike was

553   highly accurate (Supp. Fig.3B), with TM-score of 0.99 when aligned to the cryoEM

554   structure with Fab 3B4 removed. Despite the higher TM-score, AF3 reported slightly

555   lower confidence scores, with ipTM=0.78, and pTM=0.81. The AF3 predicted model for

556   3H4 additionally showed dramatic improvement from the AlphaFold 2 (AF2) prediction,

557   which did not place Fab 3H4 in the correct general placement. In the case of Fab 3B4,

558   AF3 could not successfully find the correct general placement and consistently placed

559   3B4 Fab on the side of the spike dimer (Supp.Fig.3C), even when we tried alternative

560   searches for one or two Fabs or scFvs. Because the overall interface alignment appears

561   to be slightly off in these AF3 models, this may explain why AF3 could not predict the

562   epitope of Fab 3B4 correctly, which targets the dimer interface. AF3 was less confident

563   in its predicted model of one Fab 3B4 bound to HAstV1 spike, with ipTM=0.52 and

564   pTM=0.61, but were still above the 0.5 threshold suggesting that the structure could be

565   correct despite being an incorrect placement. However, the decrease in these scores for

566   3B4 compared to 3H4 and 4B6 does suggest some ability to determine whether the

567   predicted structure is correct. From these assessments, AlphaFold 3 appears to have a

568   dramatic increase in accuracy compared to previous versions which consistently failed

569   to predict antibody interactions at all, even though some challenging antibodies which

570   target interfaces may still be more difficult.

571

Discussion:

Here, we map three new epitopes on the HAstV spike that induce neutralizing antibodies, finding that 4B6 and 3B4 target the top of the spike in ways that are unique from previously characterized antibodies. Additionally, we find that 3H4 targets the base of the spike, representing an entirely unique epitope which is distant from previously characterized antibodies and targets mostly conserved residues. With these additional structures, we find that the majority of neutralizing antibodies target the upper side or top variable loop regions of the spike (Fig. 6). These regions reside around conserved areas of the HAstV spike, termed the P-site and S-site, which were proposed as potential host protein interacting.[40] However, few of the antibody residues directly target these conserved sites. Although the direct receptor or host protein interaction locations on the spike are currently not known, it is possible that these neutralizing antibodies sterically hinder receptor binding to more conserved residues, rather than overlapping with receptor binding site(s) directly, given that the majority of neutralizing antibodies target highly variable loop residues on the top regions of the spike, indicating less functional importance for these residues. These loops may serve more as an immunogenic target for antibodies that can be more easily mutated without changing important functions of the spike. 3H4 represents an entirely new antigenic site near the base of the spike, which has less accessibility compared to the top exposed portion of the spike where the majority of antibodies target. This low epitope may have been favored more by recombinant spike immunization than what would have been induced by the whole virus where the capsid core domain limits access. This suggests the possibility of using recombinant spike vaccinations for enhancing the induction of less

595 accessible antigenic sites that may be more conserved on the spike, similar to how

596 some recombinant influenza vaccine antigen candidates better elicit immune-

597 subdominant hemagglutinin stem targeting antibodies. Given that 3H4 targets mostly

598 conserved residues and has high affinity, it may have some potential as a monoclonal

599 antibody therapy for HAstV2. However, 3H4 is vulnerable to mutations at residue K504,

600 which additionally is not conserved between HAstV serotypes.

601 We find that all three antibodies, 3H4, 4B6, and 3B4, block binding of FcRn to the

602 spike, although 3B4 only appears to partially block. From the structure, is can be seen

603 that 3B4 leans more to one side of the spike dimer than the other. It is possible that this

604 asymmetric nature of the 3B4 binding antibody could explain how only partial blocking

605 of FcRn binding occurs if FcRn were to bind both sides of the spike homodimer and 3B4

606 was capable of only blocking one side. It is interesting that all three antibodies block

607 FcRn binding given their different locations on the spike, which leads to our hypothesis

608 that the blocking ability of these antibodies may be more related to steric hinderance

609 and less related to where the antibodies bind directly. This does seem to be the case

610 given that the scFvs of 3H4 and 3B4 neutralize less effectively than full length mAb,

611 however they are still able to neutralize virus at higher concentrations, indicating that

612 there may still be some overlap with receptor-binding site(s), or that some steric

613 hinderance still occurs with the variable region.

614 Overall, these studies further our structural and mechanistic understanding of

615 neutralizing antibody epitopes on the HAstV capsid surface, supporting the rational

616 design of vaccines targeting HAstV spikes to prevent childhood viral diarrhea by HAstV.

809
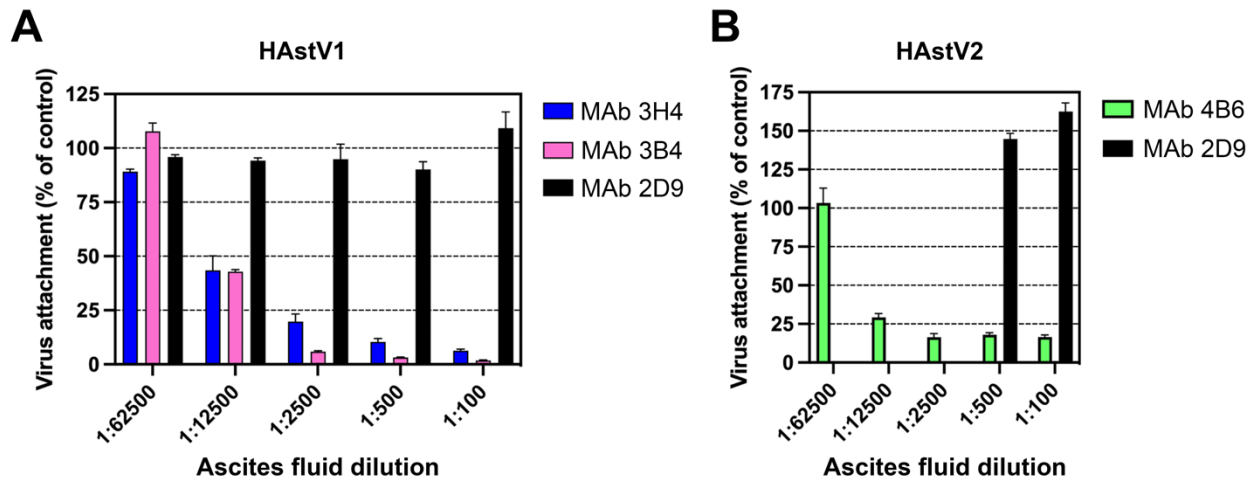

810

811

812   **Figure 1: Monoclonal antibodies to HAstV1 and HAstV2 block attachment of the**

813   **virus to Caco-2 cells.** Ascitic fluid of (A) mAbs 3B4 or 3H4 to HAstV1 or (B) mAb 4B6

814   to HAstV2 block attachment when pre-incubated with the corresponding virus before

815   cell adsorption. MAb 2D9 which is specific to serotype HAstV8 was used as a negative

816   control. Experiments were performed on ice to prevent virus endocytosis. The assay

817   was performed in biological quintuplicates and carried out in duplicate. The data are

818   expressed as percentages of the virus attached in the absence of antibodies and

819   represent the mean ± SEM.
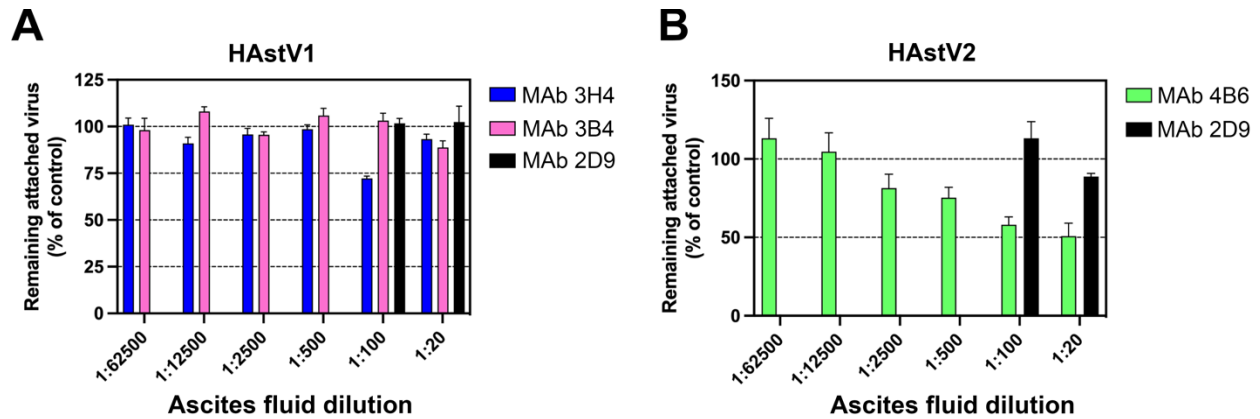

Figure 2. Monoclonal antibody detachment of HAstV previously bound to the surface of Caco-2 cells. (A) HAstV1 or (B) HAstV2 was attached to cells on ice to prevent virus endocytosis. Subsequently, either ascitic fluid of (A) mAb 3B4 or 3H4, or (B) mAb 4B6 was added to cells and incubated for 1 h on ice. The remaining attached virus was determined by RT-qPCR. MAb 2D9 which is specific to serotype HAstV8 was used as a negative control. The assay was performed in biological sextuplicates and carried out in duplicate. The data are expressed as percentages of the virus that remained attached in the absence of antibodies and represent the mean ± SEM.
Figure 3: Neutralizing antibody 4B6 binds to a unique epitope on the top of the HAstV2 spike. (A) Crystal structure of scFv 4B6 bound to the HAstV2 spike homodimer solved to 2.67 Å resolution and displayed as a ribbon model. The spike is colored grey and scFv 4B6 is colored green, with the heavy chain colored dark green and the light chain colored light green. Red panels show the locations of the focused views shown in panels C and D. (B) Surface model of the HAstV2 spike with residues involved in the

838   4B6 epitope colored in dark green for a heavy chain interactions or light green for light

839   chain interactions. The yellow residues indicate previously identified escape mutation

840   locations to antibody 4B6.[12] (C) Focused view on the light chain interaction, with 4B6

841   light chain colored light green. Side chains involved in hydrogen bonding are shown,

842   with hydrogen bonds colored magenta. 4B6 light chain predominantly interacts with

843   spike loop 3. (D) Focused view on the heavy chain interaction, with 4B6 heavy chain

844   colored dark green. 4B6 heavy chain predominantly interacts with beta sheets 8 and 11,

845   and the tip of loop 3 on the HAstV spike.
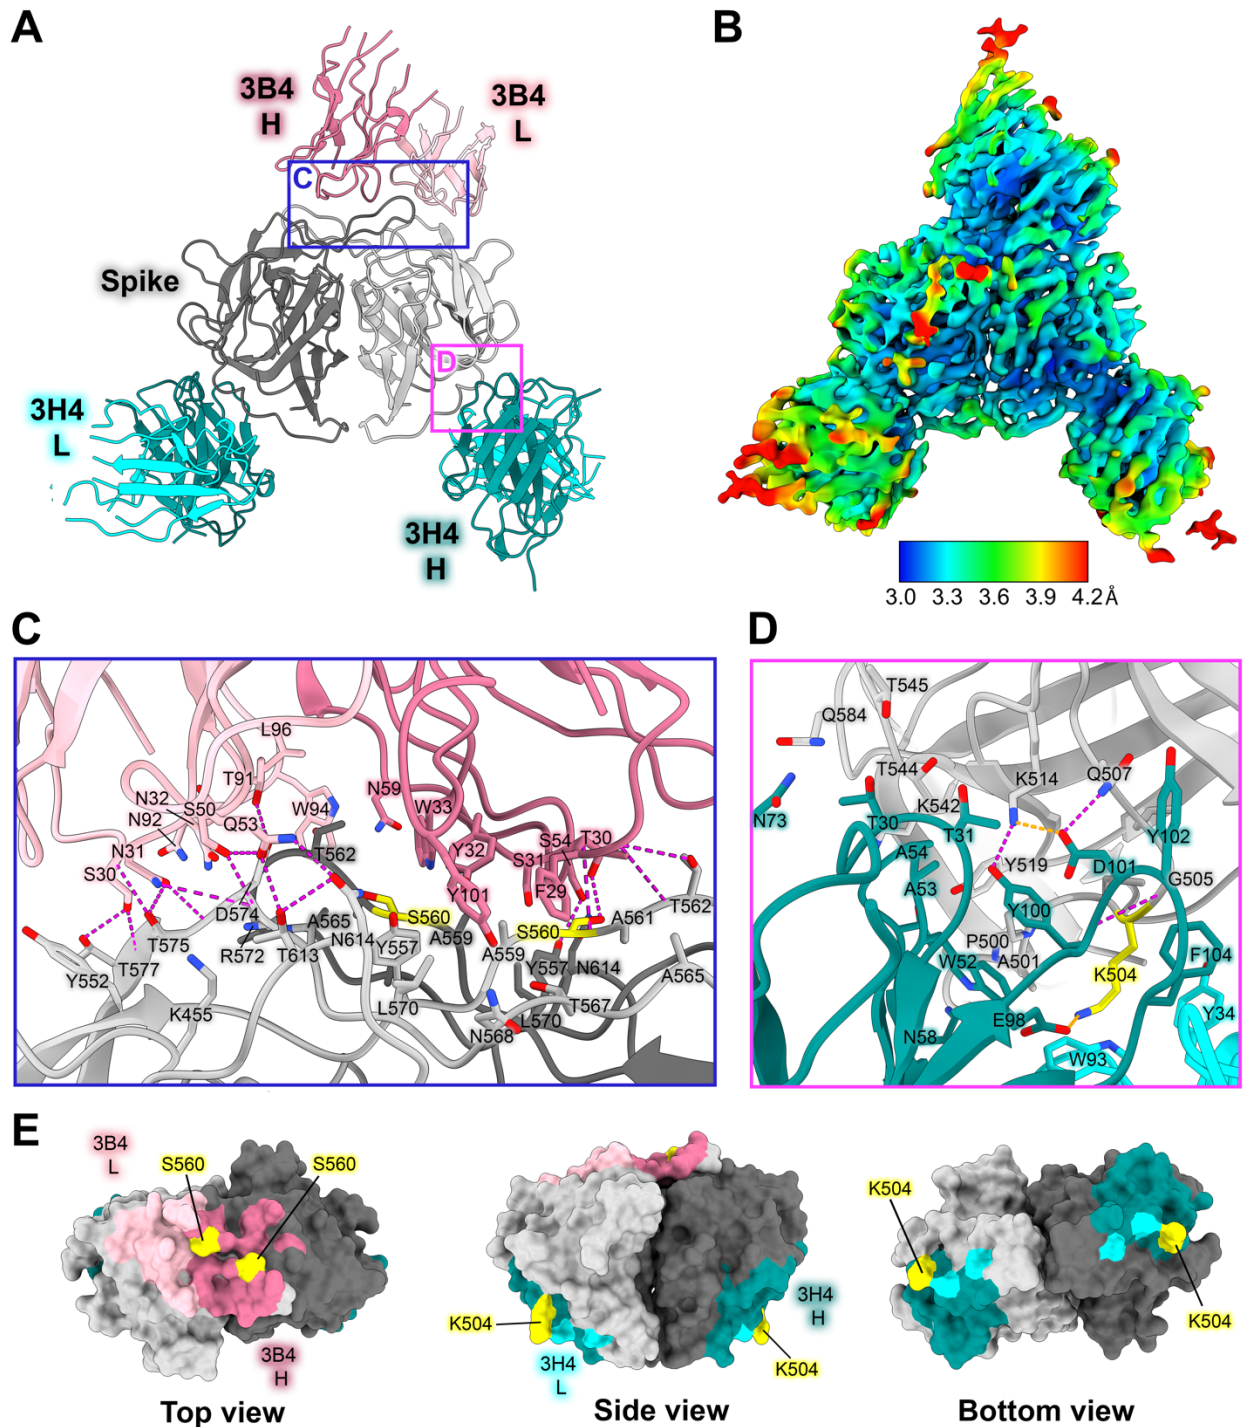

**Figure 4: Neutralizing antibody 3H4 binds to a unique epitope at the base of the spike, and neutralizing antibody 3B4 has a unique top epitope in which a single antibody binds the spike dimer interface.** (A) Single-particle cryoEM reconstructed

851   map solved to $FSC_{0.143}$ 3.33 Å of neutralizing Fab 3H4 and Fab 3B4 bound

852   simultaneously to the HAstV1 spike, displayed as a ribbon model with 3H4 colored cyan

853   and 3B4 colored pink. The heavy and light chains are colored in dark and light shades,

854   respectively. Red panels show the locations of the focused views shown in panel C and

855   D. (B) Local resolution estimation of the cryoEM structure of HAstV1 spike bound to

856   3H4 Fab and 3B4 Fab, with contour level at 0.043 in ChimeraX. (C) Focused view of the

857   3B4 epitope, with the light chain colored light pink, and the heavy chain colored dark

858   pink, with hydrogen bond interactions colored magenta. Serine 560, which was

859   previously identified as a residue that overcomes the neutralization activity of 3B4 when

860   mutated to proline, is highlighted in yellow. (D) Focused view of the 3H4 epitope, with

861   the light chain colored light cyan, and the heavy chain colored dark teal. Hydrogen bond

862   interactions are colored magenta and salt bridges are colored in orange. Lysine 504,

863   which was previously identified as a residue that overcomes the neutralization activity of

864   3H4 when mutated to glutamic acid, is highlighted in yellow. (E) Surface view of the

865   HAstV1 spike with antibody interacting residues colored according to antibody chain.

866   Residues interacting with both chains are colored according to the predominant

867   interaction. Residues that confer resistance to the respective antibody when mutated

868   are colored in yellow.

869

870
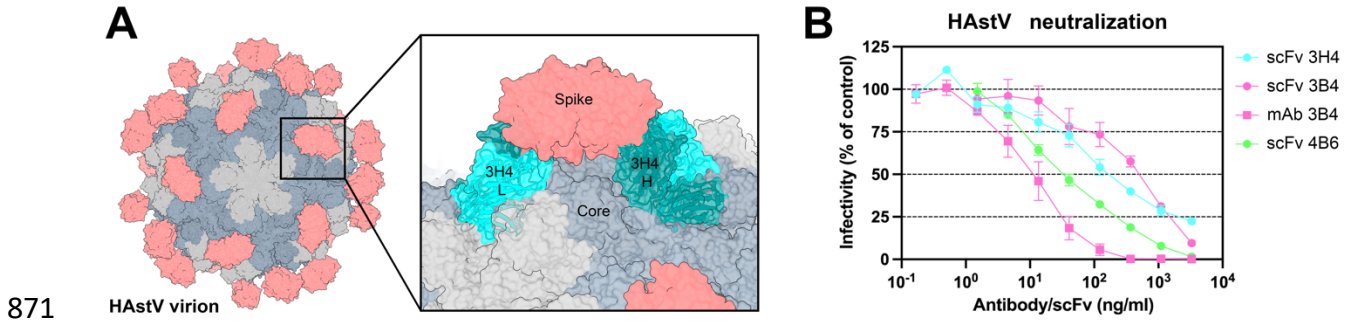

Figure 5: Steric hinderance of antibody 3H4 constant domains may play a role it its ability to neutralize HAstV1. (A) Graphic depicting the full virion capsid, with the core domains colored in grey and the spike domains colored in salmon. The panel shows a focused view of how Fab 3H4 would clash with the HAstV capsid core, using the cryoEM reconstruction of 3H4 variable domain aligned with an AlphaFold 3 model of the constant domain. (B) Neutralization activity of scFv 3H4, scFv 3B4 and mAb 3B4 against HAstV1, or scFv 4B6 against HAstV2. HAstV was preincubated with the corresponding scFv or mAb at the indicated concentrations. The infectivity of the virus was determined as described in Materials and Methods. The infectivity assay was performed in biological triplicates and carried out in duplicate. The data are expressed as % infectivity of control and represent the mean ± SEM.
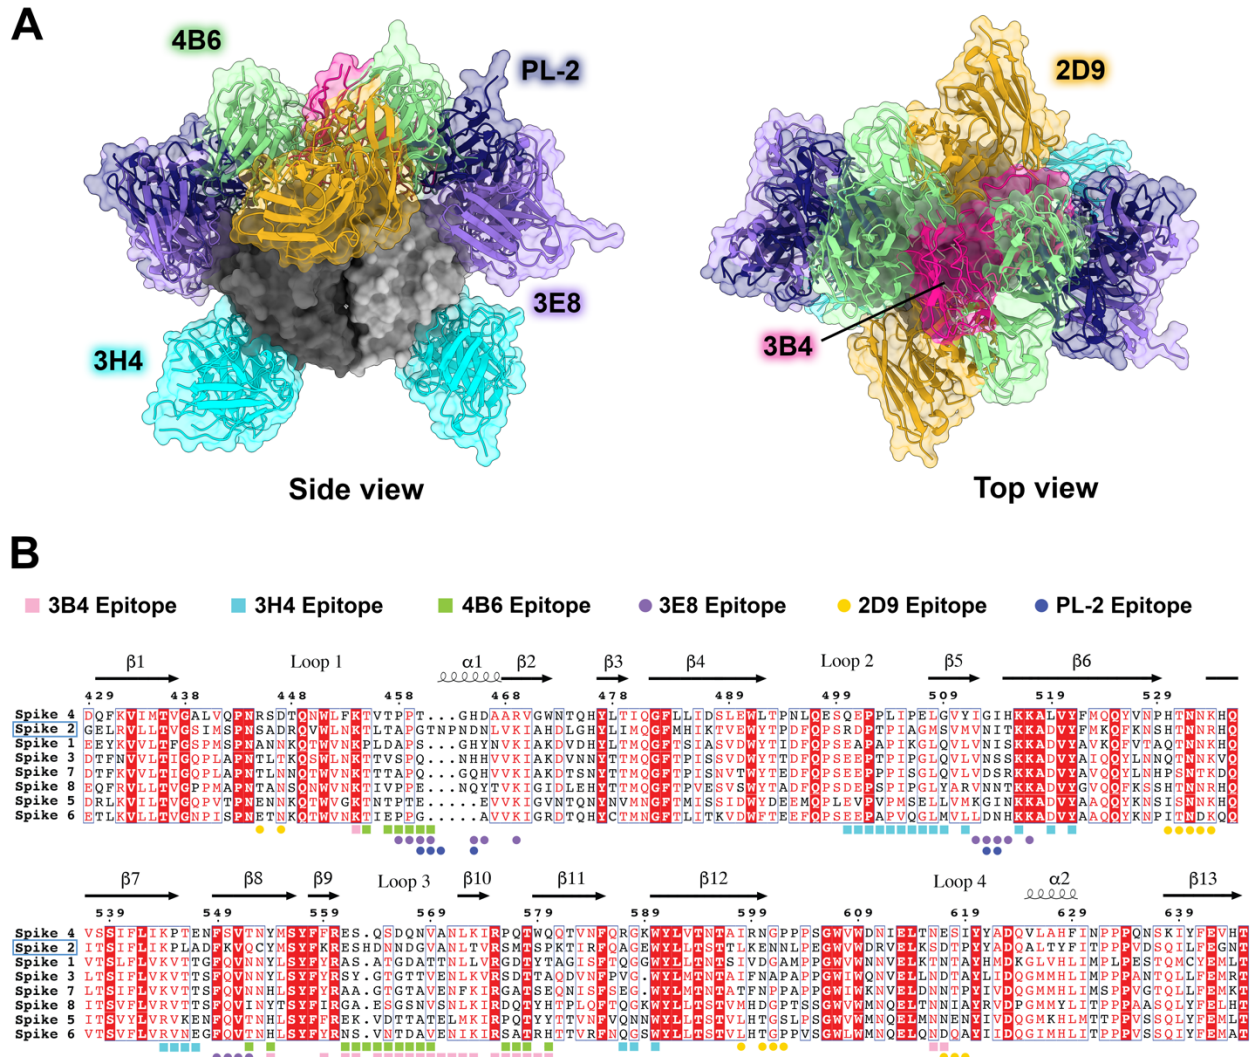

Figure 6: Comparison of all known HAstV-neutralizing antibody epitopes, showing that most target the upper variable region of HAstV spike. (A) Alignment of all existing HAstV neutralizing antibody structures 4B6, 3B4, 3H4, 3E8, 2D9, and PL-2, mapped onto HAstV1 spike. (B) Spike protein sequences of the eight classical HAstV serotypes aligned using EMBL-MUSCLE, with residues colored according to conservation. The following sequences were used for the alignment: HAstV1, GenBank #AAC34717.1; HAstV2, GenBank # KY964327.1; HAstV3, UniProt #Q9WFZ0.1;

893 HAstV4, UniProt #Q3ZN05.1; HAstV5, UniProt #Q4TWH7.1; HAstV6, UniProt

894 #Q67815.1; HAstV7, UniProt #Q96818.2; HAstV8, UniProt #Q9IFX1.2. Residue

895 numbering shown above corresponds with HAstV2. Residues highlighted in red are

896 strictly conserved, residues with red text are semi-conserved, and residues in black text

897 have little to no conservation. Spike residues interacting with the antibodies

898 characterized in this paper, 3H4, 3B4, and 4B6, are indicted with colored squares, and

899 epitope residues for antibodies that were previously characterized, 2D9, 3E8, and PL-2,

900 are indicated as colored circles.

901 **Tables**

902

903 **Table 1:** Antibodies 3B4, 3H4 and 4B6 bind HAstV spike with high affinity

Antibody to spike	Average $K_D \pm \sigma$ (nM)	χ^2	R^2
Fab 3H4 - HAstV1 spike	0.490 ± 0.002 nM	<0.2339	>0.9991
Fab 3B4 – HAstV1 spike	11.8 ± 0.5 nM	<0.7474	>0.9909
Fab 4B6 – HAstV2 spike	161 nM ± 2 nM	<0.0675	>0.9943

904

905

906 **Table 2:** Antibodies 3B4, 3H4, and 4B6 compete with FcRn receptor to HAstV spike.

	FcRn
Fab 3B4	0.394
Fab 3H4	0.035
Fab 4B6	0.063
no Fab	1.000

907
