#### ABSTRACT

#### Background

Acoustic stimulation of the fetus has been suggested to improve the efficiency of antepartum fetal heart rate testing.

#### Objectives

To assess the advantages and disadvantages of the use of fetal vibroacoustic stimulation in conjunction with tests of fetal wellbeing.

#### Search methods

We searched the Cochrane Pregnancy and Childbirth Group's Trials Register (30 September 2013).

#### **Selection criteria**

All published and unpublished randomised controlled trials assessing the merits of the use of fetal vibroacoustic stimulation in conjunction with tests of fetal wellbeing.

#### Data collection and analysis

All review authors independently extracted data and assessed trial quality. Authors of published and unpublished trials were contacted for further information.

#### **Main results**

Altogether 12 trials with a total of 6822 participants were included. Fetal vibroacoustic stimulation reduced the incidence of non-reactive antenatal cardiotocography test (nine trials; average risk ratio (RR) 0.62, 95% confidence interval (CI) 0.48 to 0.81). Vibroacoustic stimulation compared with mock stimulation evoked significantly more fetal movements when used in conjunction with fetal heart rate testing (one trial, RR 0.23, 95% CI 0.18 to 0.29).

#### **Authors' conclusions**

Vibroacoustic stimulation offers benefits by decreasing the incidence of non-reactive cardiotocography and reducing the testing time. Further randomised trials should be encouraged to determine not only the optimum intensity, frequency, duration and position of the vibroacoustic stimulation, but also to evaluate the efficacy, predictive reliability, safety and perinatal outcome of these stimuli with cardiotocography and other tests of fetal wellbeing.

#### PLAIN LANGUAGE SUMMARY

#### Fetal vibroacoustic stimulation for facilitation of tests of the wellbeing of the unborn baby

Acoustic stimulation of unborn babies may make tests on their wellbeing more effective.

Tests on unborn babies such as ultrasound, measuring the number of movements and the heart rate are carried out to check the baby's wellbeing. As a baby's sleep periods can alter these results by making it non-reactive, various methods are used to wake the baby so that it can respond to the stimulus. Fetal vibroacoustic stimulation uses a hand-held electronic device placed just above the pregnant woman's abdomen. Brief sounds are sent through the mother's abdomen to her baby. The vibroacoustic stimulation gives the opportunity to assess how the baby responds. Exposure of the baby to the vibroacoustic stimulation is generally considered safe but it can cause vigorous fetal movements and fetal distress.

This review of 12 randomised controlled trials involving 6822 mothers found that vibroacoustic stimulation improved the effectiveness of the baby's heart rate testing. However, the data on fetal distress and perinatal death were too few to draw any conclusions on safety. More research is needed to determine the optimal intensity, frequency, duration and position of the vibroacoustic stimulation and to evaluate the safety and perinatal outcomes when used with cardiotocography and other tests of fetal wellbeing.

### BACKGROUND

Antepartum fetal heart rate testing, fetal movement counts, fetal ultrasound examinations and biophysical profile of the fetus are methods of assessing fetal wellbeing. More recently vibroacoustic stimulation of the fetus is performed in conjunction with these tests.

Several studies (Ingemarsson 1989; Keegan 1987; Leader 1984; Smith 1985) have shown that fetal sleeping periods can lead to falsely non-reactive tests, thereby increasing the risk of unnecessary obstetric intervention. Various methods of stimulation have been proposed to arouse the fetus from the sleep cycle or rest-activity cycle. They include a change in maternal position, physical activity, maternal glucose ingestion, sound stimulation, light stimulation and manual fetal manipulation. If the fetus can be aroused sufficiently, such stimulations may be useful when used in conjunction with tests of fetal wellbeing.

Fetal vibroacoustic stimulation was first noted in 1947 by Bernard and Sontag (Bernard 1947), who observed that the fetal heart rate accelerated after acoustic stimulation. Sadovsky 1981 correlated fetal movements with fetal wellbeing. In modern obstetrics, vibroacoustic stimulation of the fetus is gained by using a handheld electronic device placed just above the pregnant woman's abdomen, which transmits brief sound stimuli through the abdominal wall to the fetus.

Antepartum fetal heart rate testing (cardiotocography test) has become a popular method of assessing fetal wellbeing. Acoustic stimulation of the fetus has been suggested to improve the efficiency of antepartum fetal heart rate testing (Serafini 1984; Trudinger 1980). By reducing the number of non-reactive cardiotocography secondary to fetal sleep states, the vibroacoustic stimulation test may be expected to reduce maternal and provider anxiety, shorten overall testing time and allow perinatal resources to be better utilised.

Some authors of non-randomised studies (Nyman 1992; Inglis 1993; Sarinoglu 1996) have reported success using fetal vibroacoustic stimulation to improve the efficiency of antepartum fetal heart rate testing without changing the predictive reliability of the tests.

Vibroacoustic stimulation of the human fetus profoundly alters fetal behaviour and heart rate. Fetal vibroacoustic stimulation is a stress in itself and there have been reports of severe fetal distress following vibroacoustic stimulation (Sherer 1988; Sherer 1991). Vigorous fetal movements evoked by the stimulus may result in tightening of a nuchal cord, bradycardia, and subsequent caesarean section for fetal distress. However, the available information from non-randomised controlled trials suggests that exposure of the fetus to vibroacoustic stimulation is generally clinically safe (Arulkumaran 1991; Arulkumaran 1992).

### OBJECTIVES

To assess the advantages and disadvantages of the use of fetal vibroacoustic stimulation in conjunction with tests of fetal wellbeing. In particular, to assess whether the adjunctive use of vibroacoustic stimulation to alter fetal behavioural states leads to less false positive non-reactive tests.

To assess whether the use of fetal vibroacoustic stimulation improves perinatal outcome, leads to greater maternal satisfaction, and is associated with costs savings and a shorter testing time.

#### METHODS

#### Criteria for considering studies for this review

#### **Types of studies**

All published and unpublished randomised controlled trials assessing the merits of the use of fetal vibroacoustic stimulation in conjunction with tests of fetal wellbeing. Quasi-randomised trials were excluded.

#### **Types of participants**

Pregnant women who have an antenatal non-stress cardiotocography test or other tests of fetal wellbeing in conjunction with vibroacoustic stimulation.

#### **Types of interventions**

- Vibroacoustic stimulation versus mock or no stimulation
- Vibroacoustic stimulation versus mock stimulation
- Vibroacoustic stimulation versus manual stimulation
- Vibroacoustic stimulation and cardiotocography versus cardiotocography alone
- Vibroacoustic stimulation and test of fetal wellbeing versus test of fetal wellbeing alone
- Vibroacoustic stimulation versus light stimulation

#### Types of outcome measures

#### **Primary outcomes**

- 1. Reactive cardiotocography
- 2. Palpated or visualised movements

#### Secondary outcomes

- 1. Testing time for fetal wellbeing
- 2. Need for contraction stress test
- 3. Fetal distress
- 4. Gestation at delivery
- 5. Operative delivery
- 6. Perinatal mortality
- 7. Maternal anxiety
- 8. Maternal satisfaction
- 9. Fetal hearing impairment or loss
- 10.Impaired neurological development
- 11.Testing time for modified biophysical profile (not prespecified outcome)
- 12.Non-reassuring biophysical profile (not prespecified outcome)

## Search methods for identification of studies

We searched the Cochrane Pregnancy and Childbirth Group's Trials Register by contacting the Trials Search Co-ordinator (30 September 2013).

The Cochrane Pregnancy and Childbirth Group's Trials Register is maintained by the Trials Search Co-ordinator and contains trials identified from:

- 1. monthly searches of the Cochrane Central Register of Controlled Trials (CENTRAL);
- 2. weekly searches of MEDLINE;
- 3. weekly searches of Embase;
- 4. handsearches of 30 journals and the proceedings of major conferences;
- 5. weekly current awareness alerts for a further 44 journals plus monthly BioMed Central email alerts.

Details of the search strategies for CENTRAL, MEDLINE and Embase, the list of handsearched journals and conference proceedings, and the list of journals reviewed via the current awareness service can be found in the 'Specialized Register' section within the editorial information about the Cochrane Pregnancy and Childbirth Group.

Trials identified through the searching activities described above are each assigned to a review topic (or topics). The Trials Search Coordinator searches the register for each review using the topic list rather than keywords.

We did not apply any language restrictions.

#### Data collection and analysis

For the methods used when assessing the trials identified in the previous version of this review, *see* Tan 2001.

For this update we used the following methods when assessing the trials identified by the updated search (Berclaz 1991; Bolnick 2004; Bolnick 2006; Gonzalez 1995; Gonzalez 1998; Papadopoulos 2007; Pinette 2005; Sood 2007).

#### **Selection of studies**

Three review authors independently assessed for inclusion all the potential studies we identified as a result of the search strategy. We resolved any disagreement through discussion.

#### **Data extraction and management**

We designed a form to extract data. For eligible studies, we extracted the data using the agreed form. We resolved discrepancies through discussion. We entered data into Review Manager software (RevMan 2012) and checked for accuracy.

When information regarding any of the above was unclear, we planned to contact authors of the original reports to provide further details.

#### Assessment of risk of bias in included studies

We independently assessed risk of bias for each study using the criteria outlined in the *Cochrane Handbook for Systematic Reviews of Interventions* (Higgins 2011). We resolved any disagreement by discussion.

#### (1) Sequence generation (checking for possible selection bias)

We described for each included study the method used to generate the allocation sequence in sufficient detail to allow an assessment of whether it should produce comparable groups.

We assessed the method as:

 low risk (any truly random process, e.g. random number table; computer random number generator);

**Fetal vibroacoustic stimulation for facilitation of tests of fetal wellbeing (Review)** Copyright © 2013 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

- high risk (any non-random process, e.g. odd or even date of birth; hospital or clinic record number);
- unclear risk.

#### (2) Allocation concealment (checking for possible selection bias)

We described for each included study the method used to conceal the allocation sequence and determined whether intervention allocation could have been foreseen in advance of, or during recruitment, or changed after assignment.

We assessed the methods as:

- low risk (e.g. telephone or central randomisation; consecutively numbered sealed opaque envelopes);
- high risk (open random allocation; unsealed or non-opaque envelopes, alternation; date of birth);
- unclear risk.

#### (3) Blinding (checking for possible performance bias)

We described for each included study the methods used, if any, to blind study participants and personnel from knowledge of which intervention a participant received. We considered that studies were at low risk of bias if they were blinded, or if we judged that the lack of blinding could not have affected the results. We assessed blinding separately for different outcomes or classes of outcomes.

We assessed the methods as:

- low risk, high risk or unclear risk for participants;
- low risk, high risk or unclear risk for personnel;
- low risk, high risk or unclear risk for outcome assessors.

## (4) Incomplete outcome data (checking for possible attrition bias through withdrawals, dropouts, protocol deviations)

We described for each included study, and for each outcome or class of outcomes, the completeness of data including attrition and exclusions from the analysis. We stated whether attrition and exclusions were reported, the numbers included in the analysis at each stage (compared with the total randomised participants), reasons for attrition or exclusion where reported, and whether missing data were balanced across groups or were related to outcomes. Where sufficient information was reported, or could be supplied by the trial authors, we planned to include missing data in the analyses which we undertook. We assessed methods as:

- low risk;
- high risk;
- unclear risk.
- (5) Selective reporting bias

We described for each included study how we investigated the possibility of selective outcome reporting bias and what we found.

We assessed the methods as:

- low risk (where it is clear that all of the study's pre-specified outcomes and all expected outcomes of interest to the review have been reported);
- high risk (where not all the study's pre-specified outcomes have been reported; one or more reported primary outcomes

were not pre-specified; outcomes of interest are reported incompletely and so cannot be used; study fails to include results of a key outcome that would have been expected to have been reported);

• unclear risk.

#### (6) Other sources of bias

We described for each included study any important concerns we had about other possible sources of bias.

We assessed whether each study was free of other problems that could put it at risk of bias.

- low risk of other bias;
- high risk of other bias;
- unclear whether there is risk of other bias.

#### (7) Overall risk of bias

We made explicit judgements about whether studies were at high risk of bias, according to the criteria given in the *Cochrane Handbook* (Higgins 2011). With reference to (1) to (6) above, we assessed the likely magnitude and direction of the bias and whether we considered it likely to impact on the findings.

#### Measures of treatment effect

#### Dichotomous data

For dichotomous data, we presented results as summary risk ratio with 95% confidence intervals.

#### Continuous data

For continuous data, we used the mean difference if outcomes were measured in the same way between trials. We planned to use the standardised mean difference to combine trials that measured the same outcome, but used different methods.

#### Unit of analysis issues

#### **Cluster-randomised trials**

We did not identify any cluster-randomised trials for inclusion. In future updates, if identified and found to be eligible, we will include cluster-randomised trials in the analyses along with individuallyrandomised trials. We will adjust their sample sizes using the methods described in the *Cochrane Handbook* using an estimate of the intracluster correlation co-efficient (ICC) derived from the trial (if possible), from a similar trial or from a study of a similar population. If we use ICCs from other sources, we will report this and conduct sensitivity analyses to investigate the effect of variation in the ICC. If we identify both cluster-randomised trials and individually-randomised trials, we plan to synthesise the relevant information. We will consider it reasonable to combine the results from both if there is little heterogeneity between the study designs and the interaction between the effect of intervention and the choice of randomisation unit is considered to be unlikely.

We will also acknowledge heterogeneity in the randomisation unit and perform a sensitivity analysis to investigate the effects of the randomisation unit.

#### **Cross-over trials**

This is not a valid study design for this review.

Fetal vibroacoustic stimulation for facilitation of tests of fetal wellbeing (Review) Copyright © 2013 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

#### Dealing with missing data

For included studies, we noted levels of attrition. We planned to explore the impact of including studies with high levels of missing data in the overall assessment of treatment effect by using sensitivity analysis.

For all outcomes, we carried out analyses, as far as possible, on an intention-to-treat basis, i.e. we attempted to include all participants randomised to each group in the analyses, and all participants were analysed in the group to which they were allocated, regardless of whether or not they received the allocated intervention. The denominator for each outcome in each trial was the number randomised minus any participants whose outcomes were known to be missing.

#### Assessment of heterogeneity

We assessed statistical heterogeneity in each meta-analysis using the Tau<sup>2</sup>, I<sup>2</sup> and Chi<sup>2</sup> statistics. We regarded heterogeneity as substantial if Tau<sup>2</sup> was greater than zero and either I<sup>2</sup> was greater than 30% or there was a low P value (less than 0.10) in the Chi<sup>2</sup> test for heterogeneity.

#### **Assessment of reporting biases**

Had there been 10 or more studies in the meta-analysis, we planned to investigate reporting biases (such as publication bias) using funnel plots. No meta-analysis included 10 or more studies in this update. In future updates, we will assess funnel plot asymmetry visually. If asymmetry is suggested by a visual assessment, we will perform exploratory analyses to investigate it.

#### **Data synthesis**

We carried out statistical analysis using the Review Manager software (RevMan 2012). We used fixed-effect meta-analysis for combining data where it was reasonable to assume that studies were estimating the same underlying treatment effect: i.e. where trials were examining the same intervention, and the trials' populations and methods were judged sufficiently similar. If there was clinical heterogeneity sufficient to expect that the underlying treatment effects differed between trials, or if substantial statistical heterogeneity was detected, we used random-effects metaanalysis to produce an overall summary, if an average treatment effect across trials was considered clinically meaningful. The random-effects summary was treated as the average range of possible treatment effects and we planned to discuss the clinical implications of treatment effects differing between trials. If the average treatment effect was not clinically meaningful, we did not combine trials.

If we used random-effects analyses, the results were presented as the average treatment effect with its 95% confidence interval, and the estimates of Tau<sup>2</sup> and I<sup>2</sup>.

#### Subgroup analysis and investigation of heterogeneity

We did not explore heterogeneity using subgroup analysis. If we identified substantial heterogeneity, we considered whether an overall summary was meaningful, and if it was, used random-effects analysis to produce it.

#### Sensitivity analysis

We did not perform sensitivity analyses. In future updates, if more studies are included, we will carry out sensitivity analyses to explore the effect of trial quality assessed by concealment of allocation, high attrition rates (greater than 20%), or both, with poor-quality (high risk or unclear risk of bias) studies being excluded from the analyses in order to assess whether this makes any difference to the overall result.

### RESULTS

### **Description of studies**

#### **Results of the search**

A total of 33 trials were identified from the search strategy.

#### **Included studies**

Twelve trials were eligible for inclusion. They were conducted in: California, USA (Smith 1986); Utah, USA (Sleutel 1990); New Mexico, USA (Bolnick 2006); Western Australia (Newnham 1990); Mexico (Marquez 1993); Thailand (Tongsong 1994); Greece (Salamalekis 1995;Papadopoulos 2007); Colorado, USA (Marden 1997); Turkey (Saracoglu 1999); New York, USA (Perez-Delboy 2002); and India (Sood 2007).

In all the trials, participants in the intervention groups underwent transabdominal acoustic stimulation. In the trial by Marden et al

(Marden 1997), the primary outcome was palpated or visualised fetal movements. For all the other trials, the primary outcome was fetal heart reactivity.

In Newnham 1990, the control group was subjected to manual fetal manipulation if the initial 20-minute trace was not reactive and the test was continued for another 20 minutes. In the remainder of the trials, the control group did not have manual fetal manipulation.

In Sleutel 1990, in addition to the control group, there were two intervention groups. One intervention group underwent a single five-second transabdominal acoustic stimulation while the other underwent four intermittent three-second transabdominal acoustic stimulations, each stimulus separated by two minutes.

In Bolnick 2006, in addition to the control group (no stimulation) and the intervention group (vibroacoustic stimulation), a third group was assigned to receive transabdominal light stimulation.

For further details, see Characteristics of included studies.

#### **Excluded studies**

Twenty trials were excluded. For further details, see Characteristics of excluded studies. One trial is awaiting translation (Gonzalez 1995).

### **Risk of bias in included studies**

See Figure 1 and Figure 2 for summaries of 'Risk of bias' assessments.

## Figure 1. 'Risk of bias' graph: review authors' judgements about each risk of bias item presented as percentages across all included studies.

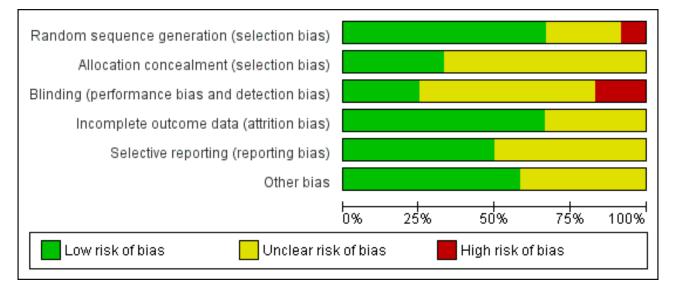

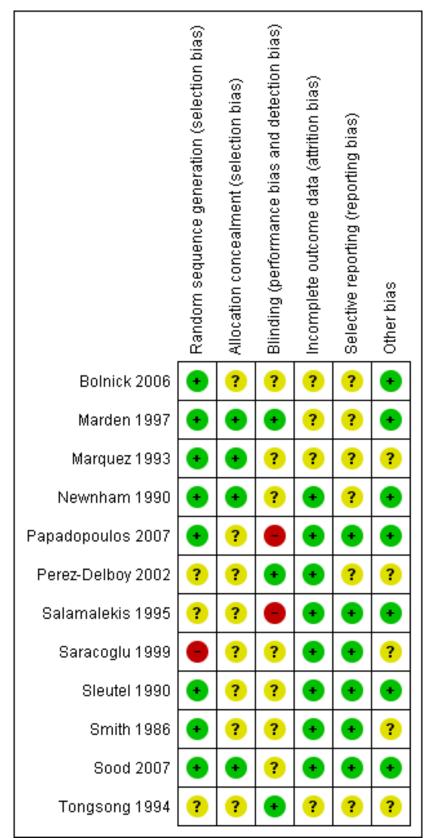

Figure 2. 'Risk of bias' summary: review authors' judgements about each risk of bias item for each included study.

#### Allocation

All the included trials were randomised but the method of randomisation varied. Three trials (Bolnick 2006; Papadopoulos 2007; Sood 2007) mentioned the use of computer-generated random numbers. Two trials (Marquez 1993; Smith 1986) mentioned the use of lottery and Sleutel 1990 used random-number tables. In one trial (Saracoglu 1999), the study participants were randomly selected from patients applying to the unit. However, the assignment to acoustic stimulation or non-stress test does not appear to be randomised but women were "divided equally" to interventions. In one trial randomisation was by draw of sealed envelopes (Newnham 1990) and in another randomisation was performed using a statistical package to generate the sequence of assignment (Marden 1997). The method of randomisation was unknown for the remaining three trials (Perez-Delboy 2002; Salamalekis 1995; Tongsong 1994).

Four trials (Marden 1997; Marquez 1993; Newnham 1990; Sood 2007) specifically mentioned the use of sealed envelopes. In the remaining trials the method of allocation concealment was unclear.

#### Blinding

The procedure of vibroacoustic stimulation was only blinded in the Marden trial (Marden 1997) in which stimulation was performed. In the trial of Tongsong (Tongsong 1994) and of Perez-Delboy (Perez-Delboy 2002), all fetal heart rate tracings were interpreted blindly by one independent perinatologist, who did not have clinical information on the group of participants.

#### Incomplete outcome data

The risk of incomplete outcome data or attrition bias was low in all studies except Bolnick 2006, Marden 1997, Marquez 1993 and Tongsong 1994. In three studies, the outcome data was not available for some participants. In at least one study (Bolnick 2006) some women discontinued the trial before completion of nonstress test.

#### Selective reporting

The reporting bias risk was low in most studies. In other cases it is difficult to assess because it was not clear whether there were any unreported findings.

#### Other potential sources of bias

In general the studies included in this review had low or unclear risk of other potential sources of bias.

#### **Effects of interventions**

A total of 12 trials with a total of 6822 participants were included.

## Fetal vibroacoustic stimulation versus mock or no stimulation (nine trials involving 3757 participants)

Fetal acoustic stimulation reduced the incidence of non-reactive cardiotocography in comparison with mock or no acoustic stimulation (nine trials; average risk ratio (RR) 0.62, 95% confidence interval (CI) 0.48 to 0.81; random-effects analysis: Tau<sup>2</sup> = 0.04; I<sup>2</sup> = 32% ), Analysis 1.1.

Fetal acoustic stimulation compared with mock or no stimulation reduced the overall mean cardiotocography testing time (three trials; average mean difference (MD) -6.93 minutes, 95% CI -12.09

minutes to -1.76 minutes; random-effects analysis: Tau<sup>2</sup> = 19.54;  $I^2$  = 97%), Analysis 1.2.

Three studies suggested that fetal acoustic stimulation reduced the false positive rate (Analysis 1.5), but not the false negative rate (Analysis 1.6) in predicting perinatal morbidity.

The data on fetal distress and perinatal death between the intervention and control groups were too few to draw any inferences. Twenty-five deaths are reported in the five trials that mentioned perinatal mortality. Similarly the data on prediction of fetal distress between the intervention and control groups were too small for any meaningful inference.

Two studies separately reported on non-prespecified outcomes such as mean testing time for modified biophysical profile and incidence of non-reassuring biophysical profile (Analysis 1.12 and Analysis 1.13). Fetal vibroacoustic stimulation was found to reduce testing time and incidence of non-reassuring biophysical profile.

## Fetal vibroacoustic stimulation versus mock stimulation (two trials involving 791 participants)

Two trials (Marden 1997; Sood 2007) compared fetal vibroacoustic stimulation with mock stimulation. However, the effect of vibroacoustic stimulation on non-reactive cardiotocography was not statistically significant (two trials, RR 0.80, 95% CI 0.43 to 1.51), Analysis 2.1. Vibroacoustic stimulation compared with mock stimulation evoked significantly more fetal movements when used in conjunction with fetal heart rate testing (one trial, RR 0.23, 95% CI 0.18 to 0.29), Analysis 2.2.

## Fetal vibroacoustic stimulation versus manual stimulation (one trial involving 172 participants)

No differences were detected in the incidence of non-reactive cardiotocography in comparison with manual stimulation of the fetus. Newnham 1990 showed no differences in the need for contraction stress test.

## Intermittent vibroacoustic stimulation versus single vibroacoustic stimulation (one trial involving 60 participants)

The data comparing intermittent versus single stimulation were too small for any meaningful inferences.

## Fetal vibroacoustic stimulation versus light stimulation (one trial involving 60 participants)

No differences were detected in the incidence of non-reactive cardiotocography in comparison with light stimulation of the fetus.

#### DISCUSSION

The benefits of using fetal vibroacoustic stimulation in conjunction with tests of fetal wellbeing must be weighed with respect to its effect on the predictive reliability of the tests and the safety of the procedure.

There is a void in the literature of randomised controlled trials relating to important outcomes such as fetal hearing impairment, impaired neurological development, gestation at delivery, maternal satisfaction and maternal anxiety. These are important safety considerations and aspects relating to hearing loss and possible cochlear damage, stress reaction and perinatal

outcome should be further studied in the context of randomised trials before recommendations are made for routine use.

Vibroacoustic stimulation offers a unique opportunity to assess how the fetus responds to the external environment. Vibroacoustic stimulation has other potential advantages in the antepartum assessment of fetal wellbeing and in provoking fetal activity to improve ultrasonic visualisation and diagnosis. Additional prospective investigation is necessary to characterise further how this technique can be more useful clinically.

#### AUTHORS' CONCLUSIONS

#### **Implications for practice**

By reducing the number of non-reactive cardiotocography secondary to fetal sleep states and reducing the testing time, fetal vibroacoustic stimulation may help perinatal resources to be better utilised. By evoking fetal movements, fetal vibroacoustic stimulation may be useful in ultrasound examination and evaluation of fetal wellbeing.

However, due to the void in the literature of randomised controlled trials relating to important outcomes such as fetal hearing impairment, impairment of neurological development, maternal satisfaction and maternal anxiety, and perinatal mortality, there is still currently insufficient evidence within randomised controlled trials based upon which a firm recommendation regarding the routine use of fetal vibroacoustic stimulation can be made.

#### Implications for research

More randomised studies are needed to define the role of fetal vibroacoustic stimulations in obstetrics. In particular, further

randomised trials should be encouraged to determine not only the optimum intensity, frequency, duration and position of the vibroacoustic stimulation, but also to evaluate the efficacy, safety and perinatal outcome of these stimuli in conjunction with cardiotocography and other tests of fetal wellbeing.

Given the large number of excluded studies, future trials should not only be of high quality but need to report outcomes of clinical relevance. There was only one trial in which the comparison was with mock stimulation. It would be good to encourage more blinded studies with mock stimulation to ensure higher quality trials. Trials with outcomes such as fetal hearing impairment, impaired neurological development, maternal satisfaction and maternal anxiety should also be encouraged.

#### ACKNOWLEDGEMENTS

Thanks to Professor James Neilson who helped to initiate and conceive this review.

As part of the pre-publication editorial process, this review has been commented on by four peers (an editor and three referees who are external to the editorial team) and the Group's Statistical Adviser.

The National Institute for Health Research (NIHR) is the largest single funder of the Cochrane Pregnancy and Childbirth Group. The views and opinions expressed therein are those of the authors and do not necessarily reflect those of the NIHR, NHS or the Department of Health.

#### Bolnick 2006

Methods

Computer-generated randomisation schedule.

Bolnick 2006 (Continued)	
Participants	The study population consisted of patients at 33 to 39 weeks of gestation who underwent an NST. Ex- cluded were cases in which the fetus had a cardiac or central nervous system anomaly or had been ex- posed to a maternal drug that affected the central nervous system or FHR beat-to-beat variability.
Interventions	Assigned to receive transabdominal light, vibroacoustic, or no stimulation. The order in which each pregnancy was assigned to receive transabdominal light, vibroacoustic, or no stimulation was deter- mined before the first of the 3 tests according to a computer-generated randomisation schedule. The minimum period between tests was 3 days.The 2 investigators who interpreted each tracing were blind- ed as to the type of stimulation.
Outcomes	Primary outcome: FHR reactivity. An adequate FHR acceleration was defined as 15 bpm above baseline for 15 seconds. If it was absent, the stimulus was repeated 10 minutes later up to a maximum of 3 times during the 20-minute NST. Primary endpoints for comparison were the time from the onset of stimula- tion until the first adequate FHR acceleration and the time before a reactive pattern (2 adequate accel- erations).

Notes

Risk of bias		
Bias	Authors' judgement	Support for judgement
Random sequence genera- tion (selection bias)	Low risk	Computer-generated randomisation schedule.
Allocation concealment (selection bias)	Unclear risk	Unclear.
Blinding (performance bias and detection bias) All outcomes	Unclear risk	Not documented if participant or caregiver blinded. 2 outcome investigators who interpreted each tracing were blinded.
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	11 cases discontinued the trial before completion of NST and data not analysed.
Selective reporting (re- porting bias)	Unclear risk	No outcomes documented in methods section.
Other bias	Low risk	No evidence of any other form of bias.

Methods	Randomisation: randomised by sealed envelopes with the use of a statistical package to generate the sequence of assignment.
Participants	Women of at least 31 weeks' gestation. Inclusion criteria included singleton pregnancy, intact mem- branes, and no concurrent use of magnesium or narcotics. Country: USA, Colorado. 577 women ran- domised.
Interventions	Women randomised to fetal acoustic stimulation group were given acoustic stimulation for 3 seconds with the stimulator placed at the midpoint between the maternal pubic symphysis and umbilicus. Fe- tal movements were palpated with the other hand at the fundus. Women randomised to control group were given mock stimulation for 3 seconds with the stimulator placed at the midpoint between the ma

Marden 1997 (Continued)	ternal pubic symphysis and umbilicus. Fetal movements were palpated with the other hand at the fun- dus.
Outcomes	Primary outcome: positive test as defined by palpation or visualisation of fetal movement only by the tester during a vibroacoustic stimulation. Other outcome: FHR reactivity.
Notes	The vibratory acoustic stimulus was performed using a vibroacoustic stimulator (Corometrics 146 fetal acoustic stimulator). Randomisation was performed after informed consent.

## Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence genera- tion (selection bias)	Low risk	Randomisation with the use of a statistical package to generate the sequence of assignment.
Allocation concealment (selection bias)	Low risk	Sealed envelopes.
Blinding (performance bias and detection bias) All outcomes	Low risk	By performing the fetal acoustic stimulation test before NST, the tester was blinded to the result of NST.
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	For 23 women, outcome data were not available. No further information pro- vided.
Selective reporting (re- porting bias)	Unclear risk	No outcomes documented in methods section.
Other bias	Low risk	No evidence of any other form of bias.

### Marquez 1993

Methods	Randomisation: randomised by lottery. Effectiveness of randomisation was assessed by comparisons of several parameters within the two groups which included gestational ages and primary indications.			
Participants	Women of least 32 wee	Women of least 32 weeks' gestation. Country: Mexico. 180 women randomised.		
Interventions	Women randomised to	Women randomised to fetal acoustic stimulation group were given acoustic stimulation for 5 seconds.		
Outcomes	Primary outcome: FHR reactivity. This was defined by the presence of 2 accelerations or more of greater than 15 bpm and of 15 seconds duration or more within a 10-minute period.			
Notes	Stimulus had an audio frequency of 75 Hz and intensity of 74 db and a stimulation duration of 5 sec- onds. Randomisation was done after informed consent.			
Risk of bias				
Bias	Authors' judgement	Support for judgement		
Random sequence genera- tion (selection bias)	Low risk	Random selection.		

## Marquez 1993 (Continued)

Allocation concealment (selection bias)	Low risk	Sealed envelopes.
Blinding (performance bias and detection bias) All outcomes	Unclear risk	Outcome assessor blinded to treatment group.
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	Unable to assess.
Selective reporting (re- porting bias)	Unclear risk	Unable to assess.
Other bias	Unclear risk	Unable to assess.

lewnham 1990			
Methods	Randomisation: randomised by draw of sealed envelopes. Effectiveness of randomisation was assessed by comparisons of several parameters within the 2 groups which included maternal ages, parities, ges- tational ages and primary indications.		
Participants		ks' gestation. Exclusion criteria - no contraindications to contraction stress tests. ralia. 172 women randomised.	
Interventions	Women randomised to fetal acoustic stimulation group were monitored for an initial 5 minutes. If the pattern is non-reactive, a 3-second vibratory acoustic stimulation was applied to the maternal ab- domen in the region of the fetal head. The stimulus was repeated a second and a third time, also at 1- minute intervals, if satisfactory FHR accelerations had not occurred. Women randomised to non-fetal acoustic stimulation group were monitored for an initial 20 minutes. If the trace was non-reactive, the fetus was stimulated manually and the test was continued for a fur- ther 20 minutes. If satisfactory accelerations were not found, the women were then sent for a meal. On her return, a nipple stimulation contraction stress was performed if the subsequent test remained non- reactive after a further 20 minutes.		
Outcomes	Primary outcome: FHR reactivity. This was defined by the presence of 2 accelerations of greater than 15 bpm and of 15 seconds' duration or more within a 20-minute period. In tests in which accelerations had been provoked by fetal acoustic stimulation, the definition of reactivity required 1 of the 2 accelerations to have been unprovoked.		
Notes	All tests were performed with Corometrics 115 monitors using Doppler FHR transducers. The tests were performed by specially trained fetal intensive care midwives with a nurse: patient ratio of 1:1. The vibratory acoustic stimulus had an audio frequency of 75 Hz, a sound intensity of 74 db at 1 m in air and a stimulation duration of 3 seconds. Randomisation was performed after informed consent.		
Risk of bias			
Bias	Authors' judgement	Support for judgement	
Random sequence genera- tion (selection bias)	Low risk	Randomisation by draw of sealed envelopes.	
Allocation concealment (selection bias)	Low risk	Sealed envelopes.	

#### Newnham 1990 (Continued)

Blinding (performance bias and detection bias) All outcomes	Unclear risk	No evidence of blinding.
Incomplete outcome data (attrition bias) All outcomes	Low risk	Follow-up 100%.
Selective reporting (re- porting bias)	Unclear risk	No outcomes documented in methods section.
Other bias	Low risk	No evidence of any other form of bias.

### Papadopoulos 2007

All outcomes

<sup>2</sup> apauopoulos 2007			
Methods	Randomisation was do	one with the use of a random number generator in the computer.	
Participants	The population of the study consisted of patients referred for fetal surveillance to the maternal-fetal medicine department (either on an outpatient basis or after admission to the hospital for various reasons). Inclusion criteria were: singleton pregnancy, gestational age equal or more than 30 weeks + 0 day and BPPS ≤ 8/10 with a non-reactive NST. Exclusion criteria were: gestational age before 30 weeks, multifetal pregnancy, premature rupture of membranes, known congenital anomalies of the fetus and maternal refuse to participate in the study.		
Interventions	The patients were followed according to department's protocol, and biophysical profile was conducted for 30 minutes according to standard criteria. All participants with an abnormal or equivocal BPPS were assigned randomly to 1 of 2 groups. In group A (study group), VAS was applied and, in group B (control group), the observation time was extended. In group A, a 3-second duration stimulus was applied with an artificial larynx placed on maternal abdomen over the fetal vertex. Following VAS, BPPS was reassessed for 30 minutes and if remained non-reassuring a second 3-second stimulus was applied. BPPS was assessed again for another 30 minutes. In group B, we followed the classical method of extended observation time for 60 minutes, divided into 2 periods of 30 minutes each to match the time periods of group A. Participants of both groups with a non-reassuring BPPS at the end of the examination were managed accordingly. BPPS with or more than 8/10 with a reactive NST at any stage was considered indicative of a non-compromised fetus.		
Outcomes	Intrauterine death, caesarean section for fetal distress, Apgar score at 5 minutes, meconium-stained amniotic fluid, admission to NICU for whatever reason.		
Notes			
Risk of bias			
Bias	Authors' judgement	Support for judgement	
Random sequence genera- tion (selection bias)	Low risk	Random number generator in the computer.	
Allocation concealment (selection bias)	Unclear risk	Unclear.	
Blinding (performance bias and detection bias)	High risk	Not performed.	

### Papadopoulos 2007 (Continued)

Incomplete outcome data (attrition bias) All outcomes	Low risk	Follow-up: 100%.
Selective reporting (re- porting bias)	Low risk	All outcomes in the methods section have been reported on in the results sec- tion.
Other bias	Low risk	No evidence of any other form of bias.

### Perez-Delboy 2002

Methods	Randomisation: randomisation method unknown.	
Participants	Women referred to antenatal testing unit for NST. Country: New York, USA. 113 women randomised.	
Interventions	Women randomised to fetal acoustic stimulation group were given 1 second vibroacoustic stimulation at the maternal abdomen. The stimulus was repeated a second (for 2 seconds) and a third time (for 3 seconds), also at 10-minute intervals, if still not reactive. Women randomised to non-fetal acoustic stimulation group were given the traditional NST without the vibroacoustic stimulation.	
Outcomes	Primary outcome: FHR reactivity.	

#### Notes

#### **Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence genera- tion (selection bias)	Unclear risk	Randomisation method unknown.
Allocation concealment (selection bias)	Unclear risk	No information provided.
Blinding (performance bias and detection bias) All outcomes	Low risk	Outcome assessor blinded.
Incomplete outcome data (attrition bias) All outcomes	Low risk	Follow-up: 100%.
Selective reporting (re- porting bias)	Unclear risk	No outcomes documented in methods section.
Other bias	Unclear risk	Unable to assess.

Methods	Randomisation: randomisation method unknown. Effectiveness of randomisation was assessed by comparisons of parities. There was no statistical significant difference.	
Participants	Women of least 37 weeks' gestation with singleton and high risk pregnancies. Country: Greece. 225 women randomised.	
Interventions	Women randomised to fetal acoustic stimulation group were monitored for at least 5 minutes. A vibra- tory acoustic stimulation was applied to the maternal abdomen in the region of the fetal head and acti- vated for 1 second 4 consecutive times, with 1 second intervals between stimulations. Women randomised to non-fetal acoustic stimulation group were monitored for an initial 20 minutes. If the trace was non-reactive, the test was continued for a further 20 minutes.	
Outcomes	Primary outcome: FHR reactivity. This was defined by the presence of 2 accelerations of 15 bpm and of at least 15 seconds' duration or a FHR acceleration of 15 bpm over the baseline for 2 minutes within 5 minutes after acoustic stimulation. Non-reactivity was defined as 40 minutes without a single FHR ac- celeration of 15 bpm or more, for 15 seconds or more. Other outcome: fetal distress within 7 days of test. This was defined by the presence of pathological FHR trace pattern, thick meconium or low Apgar at 5 minutes.	
Notes	All tests were performed with Corometrics 115 monitors. The tests were performed 1 hour after a meal in a low noise room with the mother in a semi-recumbent position to minimise the risk of supine hy- potension. The vibratory acoustic stimulus was performed using a vibroacoustic stimulator (Coromet- rics 146 fetal acoustic stimulator), with a sound intensity of 110 db in air. Randomisation after informed consent.	
Risk of bias		
Bias	Authors' judgement	Support for judgement
Random sequence genera- tion (selection bias)	Unclear risk	Allocated at random.
Allocation concealment (selection bias)	Unclear risk	Unclear.
Blinding (performance bias and detection bias) All outcomes	High risk	Not performed.
Incomplete outcome data (attrition bias) All outcomes	Low risk	Follow-up: 100%.
Selective reporting (re- porting bias)	Low risk	All outcomes in the methods section have been reported on.
Other bias	Low risk	No evidence of any other form of bias.

## Saracoglu 1999

Methods	Randomisation: randomisation method unknown.
Participants	Women seen at Perinatology Unit. Country: Turkey. 400 women randomised.

Saracoglu 1999 (Continued)	
Interventions	Women randomised to fetal acoustic stimulation group were monitored for at least 5 minutes. A vibra- tory acoustic stimulation was applied to the maternal abdomen in the region of the fetal head and acti- vated for 1 second up to 4 times.
Outcomes	Primary outcome: FHR reactivity. This was defined by the presence of 2 accelerations of 15 bpm and of at least 15 seconds' duration within a 20-minute period. Non-reactivity was defined as 40 minutes without the reactive criterion.
Notes	A fetal acoustic stimulator (Model 146; Corometrics, Wallingford, CT;75 Hz, 74 db) was used, and FHR was recorded with a fetal heart monitor (Model 115; Corometrics). The report by Saracoglu 1998 only provided data in abstract form and these were inadequate. There was no reply despite various attempts to contact the authors. The abstract was subsequently pub- lished in full (Saracoglu 1999) and the published paper (Saracoglu 1999) is included in this review.

### **Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence genera- tion (selection bias)	High risk	The study participants were randomly selected from patients applying to the unit. However, the assignment to acoustic stimulation or NST does not appear to be randomised ("divided equally").
Allocation concealment (selection bias)	Unclear risk	No information provided.
Blinding (performance bias and detection bias) All outcomes	Unclear risk	No information provided.
Incomplete outcome data (attrition bias) All outcomes	Low risk	Follow-up: 100%.
Selective reporting (re- porting bias)	Low risk	All outcomes in the methods section have been reported on.
Other bias	Unclear risk	No information provided.

#### Sleutel 1990

Methods	Randomisation: randomised by means of a random number table. 60 pregnant women at a university hospital who were scheduled for NST. Exclusion criteria were gesta- tional age less than 30 weeks, abnormal FHR, non-reactive NST or a positive contraction at the last an- tepartum evaluation, mothers who appeared sedated or had used narcotics, sedatives or street drugs within 8 hours and termination of testing on the mother or fetus before completion of NST. Country: USA, Utah.	
Participants		
Interventions	They were randomised to 3 groups (control, single stimulation and intermittent stimulation). Women randomised to control group received the traditional NST. Women randomised to the single fetal acoustic stimulation group were given acoustic stimulation for a single 5-second duration with the artificial larynx placed at the maternal abdomen over the fetal head. Women randomised to the intermittent fetal acoustic stimulation group were given acoustic stimulation for 4 3-second duration with the artificial larynx placed at the maternal abdomen over the fetal head. Each stimulus was separated by 2 minutes.	

#### Sleutel 1990 (Continued)

Outcomes	Primary outcome: FHR reactivity. This was defined by the presence of 2 accelerations of 15 bpm and of at least 15 seconds' duration within a 20-minute period. Non-reactivity was defined as 90 minutes without the reactive criterion.	
Notes	The vibratory acoustic stimulus was performed using a hand held artificial larynx with a sound pressure level in air of 100 db at 1000 Hz. Randomisation was performed after informed consent.	
Risk of bias		
Bias	Authors' judgement Support for judgement	

Random sequence genera- tion (selection bias)	Low risk	Random number table was used.
Allocation concealment (selection bias)	Unclear risk	Unclear.
Blinding (performance bias and detection bias) All outcomes	Unclear risk	No information provided.
Incomplete outcome data (attrition bias) All outcomes	Low risk	Follow-up: 100%.
Selective reporting (re- porting bias)	Low risk	2 hypotheses were stated in the methods section and both were tested.
Other bias	Low risk	No evidence of any other form of bias.

#### Smith 1986

Methods	Randomisation: randomised by lottery. Effectiveness of randomisation was assessed by comparisons of several parameters within the 2 groups which included parities, gestational ages and primary indica tions. It was noted that there was a significantly greater number of postdates women in the non-fetal acoustic stimulation group.	
Participants	Women of at least 28 weeks' gestation presenting to the Antepartum Fetal Testing Unit of the Hospital. Exclusion criteria - none. Country: USA, California. 715 women randomised.	
Interventions	Women randomised to fetal acoustic stimulation group were monitored for an initial 5 minutes. If i pattern is non-reactive, a 3 second or less vibratory acoustic stimulation was applied to the materr abdomen in the region of the fetal head. The stimulus was repeated for a maximum of 3 times, at 1 minute intervals, if satisfactory FHR accelerations had not occurred.	
Outcomes	Primary outcome: FHR reactivity. This was defined by the presence of 2 accelerations or more of greater than 15 bpm and of 15 seconds' duration or more within a 10-minute period. Non-reactivity defined as 40 minutes without 2 qualifying accelerations.	
Notes	All acoustic tests were done with a Model 5C electronic artificial larynx (Western Electric, New York) and performed in the Antepartum Fetal Testing Unit by specially trained nurses with the woman in se- mi-Fowler's position. Sound pressure levels of this device measured at 1 m in air averaged 82 db, with a fundamental frequency of approximately 80 Hz, and harmonics ranging from 20 to 9000 Hz. Randomi sation was done after informed consent.

#### **Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence genera- tion (selection bias)	Low risk	Randomised by lottery.
Allocation concealment (selection bias)	Unclear risk	Unclear.
Blinding (performance bias and detection bias) All outcomes	Unclear risk	Unclear.
Incomplete outcome data (attrition bias) All outcomes	Low risk	No patients were excluded. Those who refused participation served as a sec- ond control group.
Selective reporting (re- porting bias)	Low risk	All outcomes in the methods section have been reported on.
Other bias	Unclear risk	Unclear.

#### Sood 2007

Methods	Randomly allocated by computer-generated random numbers kept in sealed envelopes to either vi- broacoustic stimulated modified biophysical profile (VAS/mFBP) or mock stimulation (mFBP).
Participants	214 women with high risk singleton pregnancies detected amongst women attending antenatal clinic. Country: India.
Interventions	Vibroacoustic stimulation was done with EMCO vibroacoustic stimulator (EMCO Health Care Pvt Ltd, Sion, Mumbai, India) with 75 db sound intensity at 1.0 meter and frequency of 75 Hz.
Outcomes	Mean testing time for modified biophysical profile, caesarean section for fetal distress, 5 minute Apgar score < 7, admission to NICU for more than 24 hours.

Other bias	Low risk	No evidence of any other form of bias.

## Tongsong 1994

Methods	Randomisation: randomisation method unknown. Effectiveness of randomisation was assessed by comparisons of several parameters within the 2 groups which include maternal ages, gestational ages and primary indications. All the FHR tracings were interpreted blindly by 1 independent perinatologist, who did not have any clinical information on the group of women.
Participants	Women of least 28 weeks' gestation with indications including postterm pregnancy, intrauterine growth retardation, pregnancy-induced hypertension, chronic hypertension, decreased fetal move- ment and diabetes mellitus. Country: Thailand. 1273 women randomised.
Interventions	Women randomised to fetal acoustic stimulation group were given fetal acoustic stimulation for 1 sec- ond. If no qualifying acceleration was observed within 15 seconds, the stimulus were repeated up to 3 times. If reactive criteria were not achieved in 10 minutes, a new cycle of stimulation was begun. If both the women in the acoustic stimulation and standard non-acoustic stimulation groups did not meet the reactive criteria within 20 minutes of the tests, the same technique was extended another 20 minutes.
Outcomes	Primary outcome: FHR reactivity. This was defined by the presence of 2 FHR accelerations or more of greater than 15 bpm and of 15 seconds' duration within a 20-minute period. 1 prolonged acceleration of the FHR of at least 15 bpm lasting more than 2 minutes was also interpreted as reactive. If these criteria were not met in 40 minutes of monitoring, the test was interpreted as non-reactive.
Notes	All acoustic tests were performed in the Maternal Fetal Medicine Unit by a specially trained physician with the woman in semi-Fowler's position. Transabdominal acoustic stimulation overlying the fetal ver- tex was accomplished with an electronic fetal larynx of approximately 80 db and frequency of 80 Hz and a stimulation duration of 1 second. Randomisation was done after informed consent.

## Characteristics of excluded studies [ordered by study ID]

Study	Reason for exclusion
Berclaz 1991	There was a discrepancy between the number of participants presented in figure 3 (n = 18 for sham and n = 16 for real stimulation) and that stated in the text (n = 25). The definition of quiet and active fetuses was not clear. There were 2 types of bars representing <i>tranquille</i> (quiet) fetuses with different shades but no legend was given.
Devoe 1989	Data were not presented or available, or extractable as the specified clinical outcome measures for this review.
Eller 1992	Pseudo-randomisation performed using hospital odd or even number. There was a large difference between those given vibroacoustic stimulation over the fetal vertex (n = 115) and over fetal breech (n = 90). There was also discrepancy between the total numbers presented for the results relating to reactive tests (the fetal vertex (n = 96) and over fetal breech (n = 55).
Gagnon 1986	Data were not presented or available, or extractable as the specified clinical outcome measures for this review.
Gagnon 1987	Data were not presented or available, or extractable as the specified clinical outcome measures for this review.
Gagnon 1988	Data were not presented or available, or extractable as the specified clinical outcome measures for this review.
Gonzalez 1998	Data were not presented or available, or extractable as the specified clinical outcome measures for this review.
Groome 1993	Data were not presented or available, or extractable as the specified clinical outcome measures for this review.
Groome 1994	Data were not presented or available, or extractable as the specified clinical outcome measures for this review.
Hamner 1988	Data only available in abstract form and were inadequate. There was an unexplained discrepancy between the control (n = 286) and vibroacoustic stimulation (n = 135) groups.
Hasanpour 2013	Not eligible as study compared acoustic stimulation and feeding mother stimulation.
Kisilevsky 1990	Data were not presented or available, or extractable as the specified clinical outcome measures for this review.
Kisilevsky 1992	Data were not presented or available, or extractable as the specified clinical outcome measures for this review.
Maesel 1994	Data were not presented or available, or extractable as the specified clinical outcome measures for this review.

Study	Reason for exclusion
Montan 1992a	Data were not presented or available, or extractable as the specified clinical outcome measures for this review.
Montan 1992b	Data were not presented or available, or extractable as the specified clinical outcome measures for this review.
Petrovic 1998	The control group (n = 326) was larger than the study group (n = 168). The control group had 2 dis- tinct groups of which 1 group consisted of 158 women with evident fetal activity at the onset after the initial randomisation by schedule and the second group comprised 168 women after randomi- sation with no distinct fetal heart activity. These 2 distinct groups are analysed together as the con- trol group. Analyses of the results of the 2 groups separately were not available.
Pinette 2005	Quasi-randomisation performed using hospital odd or even number.
Schiff 1992	The results of the experimental group were compared to a big group (both experimental and con- trol) and presented. Results relating to the control group alone were not available and not ex- tractable.
Smith 1988	The women were randomised but only women delivering within 7 days of a reactive cardiotoco- graph test were reported. There were 314 women in the control group and only 227 women in the study group. There is also a higher incidence of postdatism in the control group.

#### WHAT'S NEW

Date	Event	Description
30 September 2013	New search has been performed	Search updated. Methods updated.
30 September 2013	New citation required but conclusions have not changed	Three new trials (Bolnick 2006; Papadopoulos 2007; Sood 2007) included.

#### HISTORY

Protocol first published: Issue 4, 1998 Review first published: Issue 1, 2001

Date	Event	Description
1 October 2009	Amended	Search updated. Six reports added to Studies awaiting classifica- tion (Bolnick 2004; Bolnick 2006; Gonzalez 1998; Papadopoulos 2007; Pinette 2005; Sood 2007).
3 November 2008	Amended	Converted to new review format.
25 November 2003	New search has been performed	Two new trials (Saracoglu 1999 and Perez-Delboy 2002) are in- cluded but they do not change the conclusions of the review.

#### **CONTRIBUTIONS OF AUTHORS**

In the update for September 2013, KH Tan, R Smyth and X Wei independently reviewed the new studies and discussed together.

## DECLARATIONS OF INTEREST

None known.

## SOURCES OF SUPPORT

### **Internal sources**

• Department of Maternal Fetal Medicine, KK Women's & Children's Hospital, Singapore.

### **External sources**

• No sources of support supplied

### DIFFERENCES BETWEEN PROTOCOL AND REVIEW

Additional comparison added - vibroacoustic stimulation versus light stimulation.

Two new outcomes were added in the 2013 update.

- 1. Testing time for modified biophysical profile (not prespecified outcome).
- 2. Non-reassuring biophysical profile (not prespecified outcome).
