Efficacy, safety, and immunogenicity of biosimilars compared with the biologic etanercept in patients with rheumatoid arthritis: a systematic review and meta-analysis

Aurélio Matos Andrade^{1,2*} , Juliana da Motta Girardi³ , Erica Tatiane da Silva² ,
Jakeline Ribeiro Barbosa⁴  and Daniella Cristina Rodrigues Pereira² 

Abstract

Background Biosimilar etanercept presents itself as an innovative therapeutic opportunity for inflammatory and autoimmune diseases, however, its efficacy, safety, and immunogenicity in relation to the reference biological agent for the treatment of rheumatoid arthritis is still questioned. With this in mind, this study aimed to verify the efficacy, safety, and immunogenicity of the use of the biosimilar etanercept in relation to the reference biologic in patients over 18 years of age with rheumatoid arthritis.

Methods A systematic review with meta-analysis was performed in accordance with the parameters of the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) selecting only Phase III randomized clinical trials. The search strategy was constructed with the MeSH terms “Etanercept”, “Biological Products”, “Arthritis, Rheumatoid”, “Biosimilar Pharmaceuticals” and was performed in Medline via PubMed, Embase, the Cochrane Library, Web of Science, EBSCO and Lilacs in January 2023. The analysis measures were relative risk (RR) for dichotomous data and mean difference (MD) for continuous data. The statistical analysis for preparing meta-analyses was developed by the Review Manager 5.1.4 software.

Results This systematic review selected 6 eligible studies with a sample population of $n = 2355$. The main efficacy outcomes showed that both drugs did not present statistically significant differences in ACR20, ACR50, and ACR70 responses within 6 months (RR 1.00; 95% CI = 0.94 to 1.07; RR 1.09; 95% CI = 0.94 to 1.26; RR 1.04; 95% CI = 0.82 to 1.31, respectively), with I^2 ranging from 55 to 63% and $0.04 \leq P \leq 0.08$. Adverse events were mostly mild or moderate, and serious adverse events were not statistically significant. Regarding immunogenicity, only 5.4% of the ADA-positive biosimilar group had positive neutralizing antibodies.

Conclusions Thus, this review found that biosimilar etanercept had efficacy, safety, and immunogenicity similar to those for the biological reference.

Systematic review registration This systematic review was registered on the PROSPERO platform under number CRD42020166610.

Keywords Etanercept, Efficacy, Arthritis Rheumatoid, Systematic Reviews, Biosimilar pharmaceuticals

Introduction

Rheumatoid arthritis (RA) is a chronic and systemic inflammatory disease that mainly affects joints, such as the hands, wrists, elbows, knees, ankles, feet, shoulders, and cervical spine. With disease progression, patients develop an inability to perform daily activities [1]. Its cause is still unknown, but it is known that it is an autoimmune disease that can present in a mild, moderate, or severe form [2]. The incidence of RA is higher among people aged 50 years or older, and it affects twice as many women as men [3, 4].

The treatment of patients with RA involves a combination of educational, preventive, and nonpharmacological interventions, pharmacological treatment, and surgical procedures [1, 5]. Among the five classes of drugs available to treat RA (analgesics, nonsteroidal anti-inflammatory drugs, corticosteroids, disease-modifying antirheumatic drugs (DMARDs), and targeted therapy with biological agents), biological agents represent notable advances in RA treatment, improving the quality of life of patients. These drugs act by blocking tumor necrosis factor (TNF) to inhibit the immune system and, consequently, reduce joint inflammation [3, 5].

Biological drugs are defined by the World Health Organization (WHO) as drugs extracted from biological fluids or tissues of animal origin or drugs obtained by biotechnological procedures [1, 6]. They are produced by biosynthesis in living cells by means of a microorganism, plant cell, or animal cell. However, biological, physical, and chemical tests are necessary to ensure quality in manufacturing processes [7].

Both biologics and biosimilars to etanercept are options when the response to one or more DMARDs is unsatisfactory for the treatment of RA [3]. Biosimilar medicines are biological products that are highly similar to reference products but are not identical [6]. Biosimilarity cannot be interpreted as evidence for interchangeability, as with generic drugs. This similarity is confirmed by randomized clinical trials in the pharmacokinetic, pharmacodynamic, safety, immunogenicity, and efficacy stages [8–10].

Because of the high costs associated with the use of biologics for the treatment of RA, the development and use of biosimilars have been proposed as a promising alternative to reduce the economic impact [9, 11]. In this context, the incorporation of biosimilars for RA is still a major challenge in health systems, and studies on the economic aspects as well as efficacy, safety, and immunogenicity are needed to guide the decision-making process [12].

Therefore, the aim of the present study was to compare the evidence on the efficacy, safety, and immunogenicity of biosimilar etanercept with those for the biologic

etanercept (ETN) for patients over 18 years of age with RA.

Method

Study identification

This was a systematic review structured in accordance with the parameters of the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) [13] protocol and registered on the PROSPERO platform (CRD42020166610). The research question was developed using the PICOS framework: “What is the safety, efficacy, and immunogenicity of biosimilars compared with that for biologic etanercept for patients 18 years of age (adults and elderly) with rheumatoid arthritis?” (Supplementary material 1). The literature search strategy was constructed using the following keywords: “Etanercept”, “Biological Products”, “Arthritis, Rheumatoid”, “Biosimilar Pharmaceuticals” applied in a structured manner and with the necessary specificities for each electronic database: MEDLINE via PubMed, EMBASE, The Cochrane Library, Web of Science, EBSCO, and Lilacs. The search was performed in January 2023.

Eligibility criteria

The inclusion criteria were phase III randomized controlled clinical trials (phase III RCTs) that compared the biologic drug etanercept with biosimilars in patients aged 18 years or older with mild, moderate, or severe rheumatoid arthritis, without restrictions for time or language.

Phase I, II, and III RCTs associated with observational studies, case series, overviews, letters to the editor, qualitative studies, and articles with incomplete texts; studies that did not address the safety, efficacy, effectiveness, and immunogenicity of biologic/biosimilar etanercept; and studies that investigated only other drugs for the treatment of RA without evidence of the use of biologic/biosimilar etanercept were excluded. A search in gray literature was not relevant because only phase III RCTs were included in the analyses.

Selection of studies and data collection

Mendeley reference manager version 1.18 was used to organize the articles and remove duplicates, and the Rayyan QCRI platform was used to select the articles (<https://rayyan.qcri.org>) for which the title and abstract were read by two independent researchers (AMA and JMG). Disagreements were resolved independently by a third researcher (DCRP).

Data extraction was performed independently by two reviewers (AMA and JMG) using an extraction form in Microsoft Excel 2016, and discrepancies were resolved by

consensus with a third researcher (JRB). Study registration was verified on the clinicaltrials.gov platform. When necessary, the authors of the selected articles were contacted to provide additional information, as were experts in the field of rheumatology. Manual searches were also carried out in the references of selected studies. The data extraction form included the following variables: authors, year of publication, country, study design, objective, population, number of participants, control group, exposed group, dosage, treatment follow-up time, efficacy, adverse events (AEs), immunogenicity, limitations, and main findings.

Among the outcomes analyzed, ACR20, ACR50, ACR70 (i.e., 20%, 50%, and 70% reduction in the number of swollen and painful joints, respectively) and improvement in 3 of the following 5 variables stipulated by the *American College of Rheumatology* (ACR) were considered for efficacy: acute phase inflammatory tests (C-reactive protein (CRP) or erythrocyte sedimentation rate (ESR), physician's global assessment, patient's global assessment, Health Assessment Questionnaire (HAQ) and visual analog pain scale [14]. For safety, serious and nonserious AEs were considered, differentiated by the classification used in the primary studies. For immunogenicity, the presence or absence of anti-drug antibodies (ADAs) was considered.

Risk of bias and quality of evidence

The methodological quality of the included studies was assessed using the Cochrane Collaboration risk of bias (ROB) tool (version 2.0), and the Robvis tool (risk of bias visualization) was used to generate signal plots and the summary plot [15, 16].

Risks of bias were independently assessed by two reviewers (AMA and JMG), and discrepancies were resolved by consensus with a third reviewer (ETS). ROB 2.0 consists of five risk of bias domains: randomization process; deviations from the intended interventions; lack of outcome data; result measurement; and selection of the reported outcome. The risk of bias for each domain was assessed as low, some concern, or high [15, 16].

GRADEpro online software was used to assess the quality of the evidence (<https://grade.org/>). *Grading of Recommendations Assessment, Development, and Evaluation* (GRADE) allows a critical evaluation of the quality of evidence for each outcome, considering four levels that represent the confidence of the estimate of the effects presented as very low, low, moderate, or high [17].

Statistical analysis

Review Manager[®] software, version 5.1.4, was used to prepare the meta-analyses for the outcomes evaluated,

considering a follow-up period of up to 6 months and above. The disease activity score (DAS) results are presented descriptively, considering that it was not possible to summarize them through a meta-analysis. Sensitivity analysis was carried out in studies by a subgroup of countries from the same continent.

Relative risk was calculated for the dichotomous outcomes, and the differences in the standard deviations and the means were calculated for the continuous outcomes, with a 95% confidence interval (CI) provided for both. A random effects model was used due to the heterogeneity of the included studies. Heterogeneity was assessed using the Cochrane criteria, being statistically significant if $P < 0.05$ for the chi-square test, and $I^2 < 25\%$ indicating low heterogeneity, $25 < I^2 < 50\%$ indicating moderate heterogeneity, and $I^2 > 50\%$ indicating high heterogeneity [18].

Results

Characterization of the included studies

In the literature search, 1370 publications were retrieved, from which 8 publications were selected, 6 of which were multicenter studies, with follow-up times of 1 to 2 years (Fig. 1).

Biologic ETN was compared with the following biosimilars: HD203 (25 mg), GP2015 (50 mg), LBEC (50 mg) and SB4 (50 mg). Of the six studies, two used GP2015, two used LBEC, one used SB4 and one used HD203. All studies had as a prerequisite that the patients were already taking a stable dose of methotrexate (MTX) ranging from 7.5 to 25 mg/week, and three studies required folic acid (5 mg/week) together with MTX. Five studies used 50 mg of biosimilar/biologic etanercept once a week. The details of the studies are presented in Table 1.

Risk of bias and quality of evidence

All studies were assessed as having a low risk of bias (Fig. 2). Regarding the critical aspects, in the allocation confidentiality domain, only Emery et al. [20–22] did not clarify the allocation confidentiality procedure. Regarding the blinding of participants and staff and the blinding of outcome assessors, Emery et al. [20–22] and Park et al. [26] presented a high risk of bias due to the open-label extension without blinding the study investigators. In the incomplete outcomes and selective reporting of outcomes domains, Park et al. [26] did not report the loss of a patient, and Matucci-Cerinic et al. [25] did not mention the secondary outcomes listed in the registered protocol.

The quality of the evidence, as determined using GRADE, was considered high for almost all outcomes. There was only a one-point reduction in inconsistency

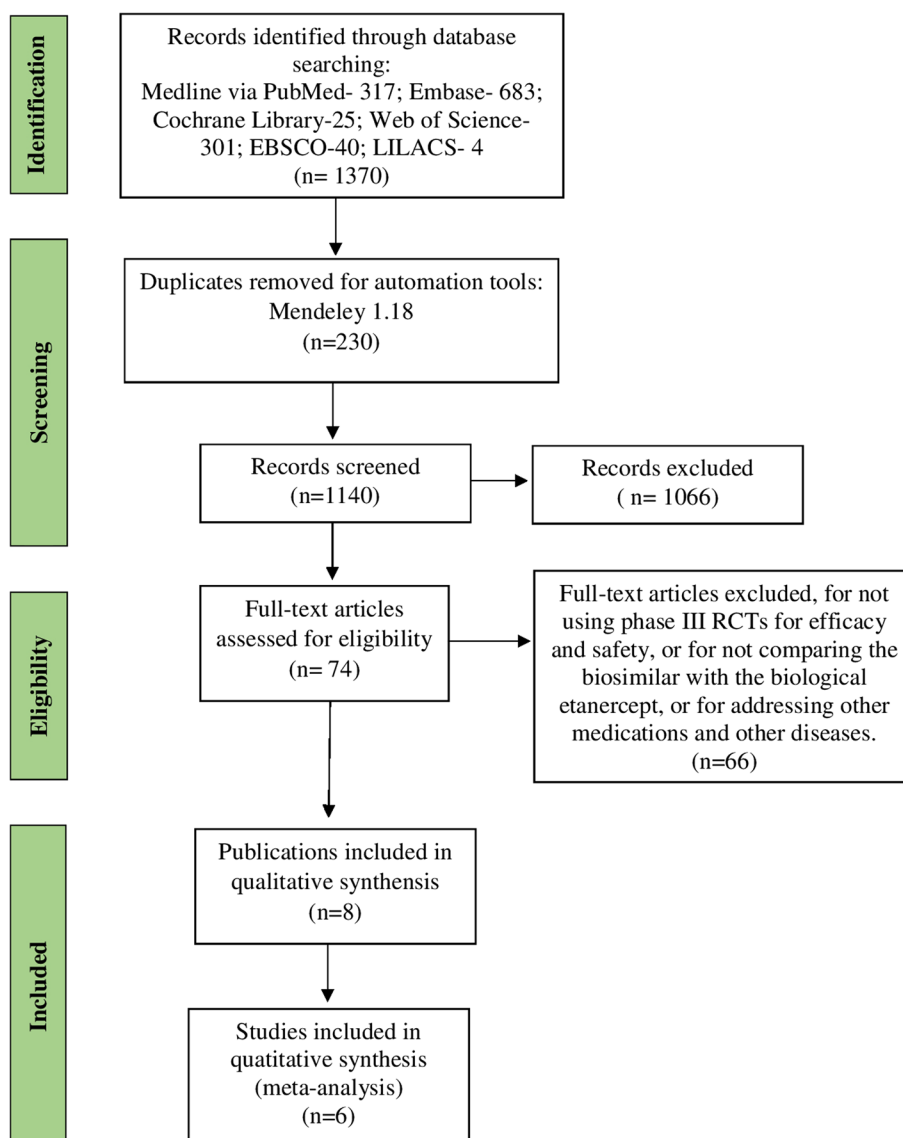

Fig. 1 Flowchart for the inclusion of studies in the systematic review. Source: Adaptation of the PRISMA flow diagram

due to the high heterogeneity in the ACR20, ACR50, and ACR70 outcomes (Supplementary material 1).

Efficacy

There were no statistically significant differences between the drugs in the ACR20, ACR50, and ACR70 responses up to 6 months (RR 1.00; 95% CI=0.94 to 1.07; RR 1.09; 95% CI=0.94 to 1.26; RR 1.04; 95% CI=0.82 to 1.31, respectively), with I^2 ranging from 55 to 63% and $0.04 \leq p \leq 0.08$ (Fig. 3); there were also no differences for these outcomes (ACR20, ACR50, ACR70) after 6 months (RR 1.03; 95% CI=0.99 to

1.07; RR: 1.08; 95% CI=0.99 to 1.18; and RR 1.04; 95% CI=0.92 to 1.18, respectively), with I^2 ranging from 0 to 17% and $0.30 \leq P \leq 0.97$ (Fig. 4).

For the evaluation of efficacy based on the DAS28 score (disease activity score in 28 joints), a decrease in the number of painful and overly inflamed joints was observed at baseline and after the intervention, but without statistically significant differences between the groups. In addition, all studies showed clinical disease remission, with predominantly good or moderate EULAR (*European League Against Rheumatism*) response in the biosimilar

group (ranging from 85.5% to 97.6%) and in the biologic etanercept group (ranging from 89.7 and 97.4%).

HAQ scores were not statistically significant in either group. The mean difference (MD) between the groups up to 6 months was (MD 0.01; 95% CI = -0.05 to 0.07; $I^2=0\%$; $P=0.89$) and above 6 months was (MD 0.03; 95% CI = -0.05 to 0.11; $I^2=0\%$; $p=0.42$), without significant heterogeneity. Only the study by Bae et al. [19] reported HAQ scores at 48 weeks were not with a significant difference in means (RR 0.04; 95% CI = -0.08 to 0.22), compared with those in other studies (Supplementary material 1).

Safety

The following severe AEs cited in primary studies [19–26] were considered in the analysis: acute pyelonephritis, arthralgia, acute cholecystitis and osteomyelitis, pneumonia, vertebral compression fracture, and severe infection (such as sepsis, abscess, opportunistic infections or invasive fungal infection, including histoplasmosis). For this review, nonsevere events were those stipulated as moderate and mild in the primary studies.

The results of the meta-analyses of nonsevere AEs evaluated up to 6 months were as follows: increase in alanine aminotransferase (RR 1.20; 95% CI = 0.65 to 2.20; $P=0.37$), urinary tract infection (RR 0.77; 95% CI = 0.36 to 1.63; $P=0.48$), injection site reaction (RR 0.34; 95% CI = 0.20 to 0.57; $P=0.67$) and nasopharyngitis (RR 0.89; 95% CI = 0.52 to 1.53; $P=0.18$); only one study showed moderate heterogeneity ($I^2=42\%$). The nonserious AEs evaluated above 6 months were cough (RR 1.20; 95% CI = 0.65 to 2.20; $P=0.37$), upper respiratory tract infection (RR 1.00; 95% CI = 0.70 to 1.44; $P=0.44$), injection site reaction (RR: 0.31; 95% CI = 0.15 to 0.63; $P=0.48$), erythema at the injection site (RR 0.20; 95% CI = 0.12 to 0.34; $P=0.77$), rash at the injection site (RR 0.21; 95% CI = 0.10 to 0.42; $P=0.52$), and nasopharyngitis (RR 1.10; 95% CI = 0.79 to 1.53; $P=0.72$), with low heterogeneity ($I^2=0\%$ and $P>0.05$) among all events analyzed in this meta-analysis (Supplementary material 1).

The severe AEs analyzed were not statistically significant and had low heterogeneity up to 6 months (RR 0.47; 95% CI = 0.10 to 2.10; $I^2=8\%$; $P=0.30$) and above 6 months (RR: 1.23; 95% CI = 0.85 to 1.78; $I^2=0\%$; $P=0.45$) (Supplementary material 1). Studies [19–22, 24, 25] also reported eight deaths: four related to the biosimilar and four related to biologic ETN. However, one death was not associated with the use of ETN (family history and habits) [25].

Immunogenicity

The presence of positive anti-drug antibodies (ADAs) was evidenced in all studies, totaling 110 patients in the

ETN group and 74 patients in the biosimilar group. Five studies [19–22, 25, 26] reported 11 patients (10%) in the biologic ETN group and two studies [19–22] reported 4 patients (5.4%) in the biosimilar group positive for the presence of neutralizing antibodies (Supplementary material 1). However, two studies [23, 24] did not detect positive neutralizing antibodies in any of the patients.

Sensitivity analysis

Sensitivity analyses were conducted to explore potential outcomes in the subgroup that analyzed only Asian countries (South Korea and Japan) [19, 24, 26]. Study exclusion by country did not produce significantly different relative risk (RR) in most cases (ACR, 20, 50, 70 up to 6 months, ACR 20, 70 above 6 months, HAQ above 6 months, Nasopharyngitis above 6 months, Upper Tract Respiratory infection above 6 months, Injection site reaction above 6 months, and serious adverse events above 6 months (Supplementary material 1), however, significant statistical differences were evidenced for rheumatoid arthritis in the grouped RR results for ACR 50 above 6 months. Three studies [19, 24, 26] (RR 1.14; 95% CI = 1.03 to 1.27; $I^2=0\%$; $P=0.01$) (Supplementary material 1).

Discussion

This systematic review with meta-analysis revealed similar statistical analyses results for efficacy, safety, and immunogenicity. The evaluation of efficacy using the ACR, DAS28, and HAQ showed similar changes between the two groups. Nonserious AEs occurred mostly after 6 months; however, serious AEs were mostly identified within 6 months. ADAs were reported in a small proportion of patients.

Regarding efficacy, there was no statistically significant difference in the DAS28, ACR, and HAQ outcomes between biosimilar and biological treatments. The scientific literature comparing biosimilars with biological etanercept in phase III RCTs is still sparse. Nevertheless, some evidence with synthetic anti-TNF drugs corroborated the findings herein, for example, Costa et al. [27], who evaluated infliximab and MTX, and Machado et al. [28], who evaluated adalimumab, both for the treatment of RA.

Regarding efficacy, there was no statistically significant difference in the DAS28, ACR, and HAQ outcomes between biosimilar and biological treatments. Clinical trials demonstrated that the response to treatment with the biosimilar, measured by the ACR20/50/70 criteria, is not inferior to that observed with the ETN biologic. Furthermore, the reduction in DAS28 was similar between the two groups, corroborating the efficacy of the biosimilar in reducing disease activity. The scientific

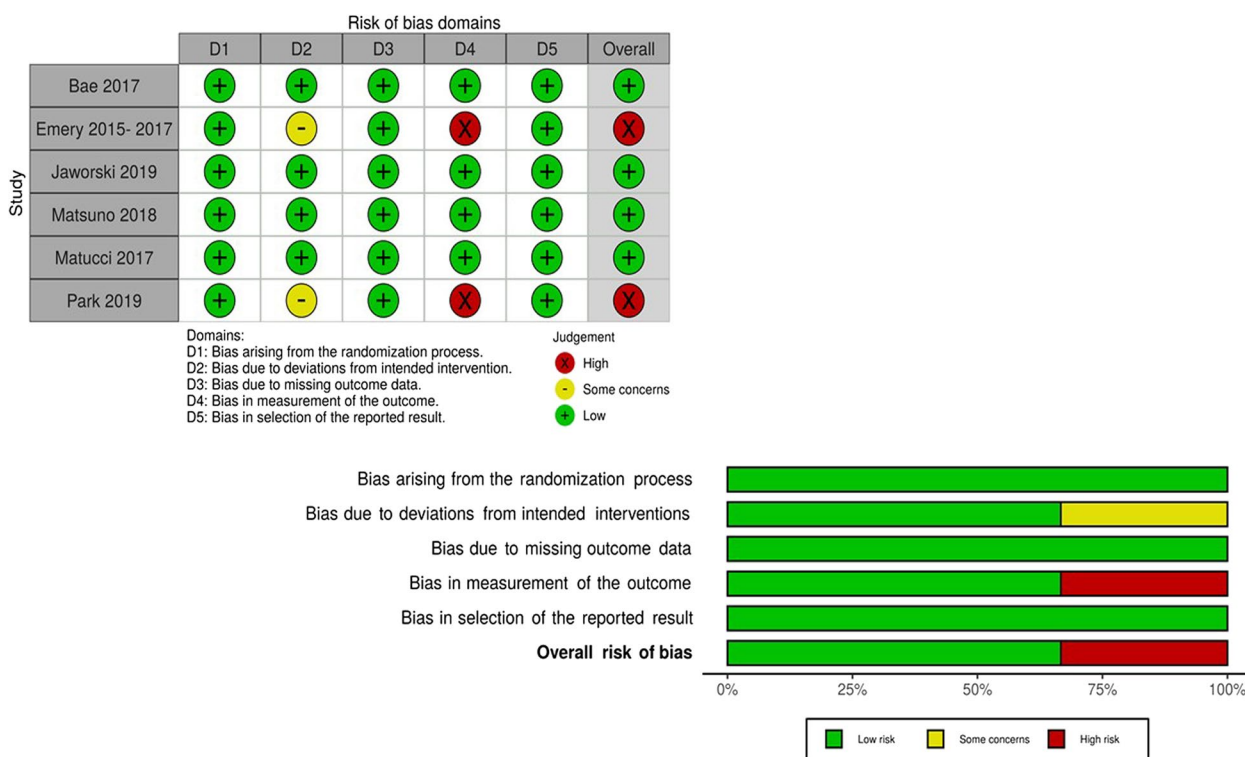

Fig. 2 Risk of bias of the studies included in the systematic review. Source: Prepared by the authors

literature comparing biosimilars with biological etanercept in phase III RCTs is still sparse, especially with larger sample sizes and studies monitoring long-term post-marketing efficacy. Nevertheless, some evidence with synthetic anti-TNF drugs corroborated the findings herein, for example, Costa et al. [27], who evaluated infliximab and MTX, and Machado et al. [28], who evaluated adalimumab, both for the treatment of RA.

The heterogeneity was high for ACR20, ACR50, and ACR70 outcomes within 6 months but was low above 6 months. This can be explained by the greater loss to follow-up with the prolongation of phase III RCTs. However, caution is required in the interpretation of long-term outcomes because studies with a follow-up above 6 months are scarcer. Previous evidence has suggested high heterogeneity with synthetic anti-TNF above 6 months [29–32]. These divergences may be associated with the relative statistical variability and methodological differences between studies and their outcomes, which may occur due to intrastudy or inter-study variance [33].

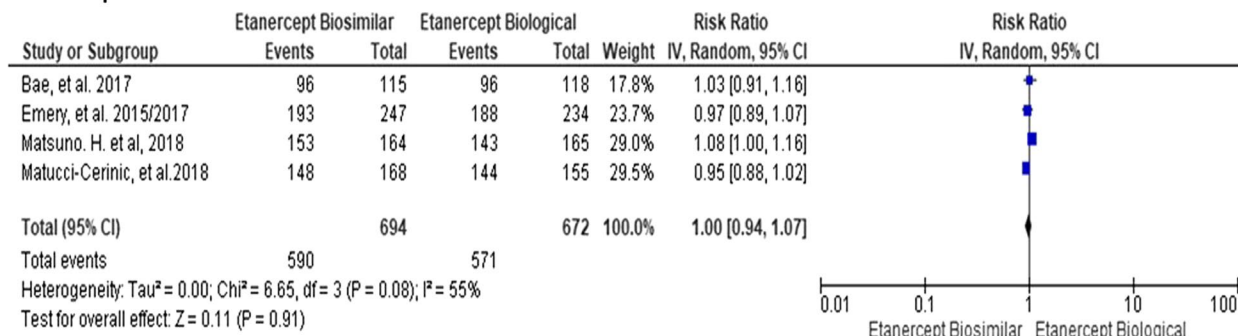

In the sensitivity analysis, ACR 50 over 6 months showed a 14% increase in risk for biosimilar etanercept in relation to biological etanercept in Asian countries, despite being a small percentage in the study by Bae et al. [19] This direction was ratified, as it was found that there

was a greater chance of type I error when analyzing the ACR50 response rates, thus reaching a result that could actually have happened by chance.

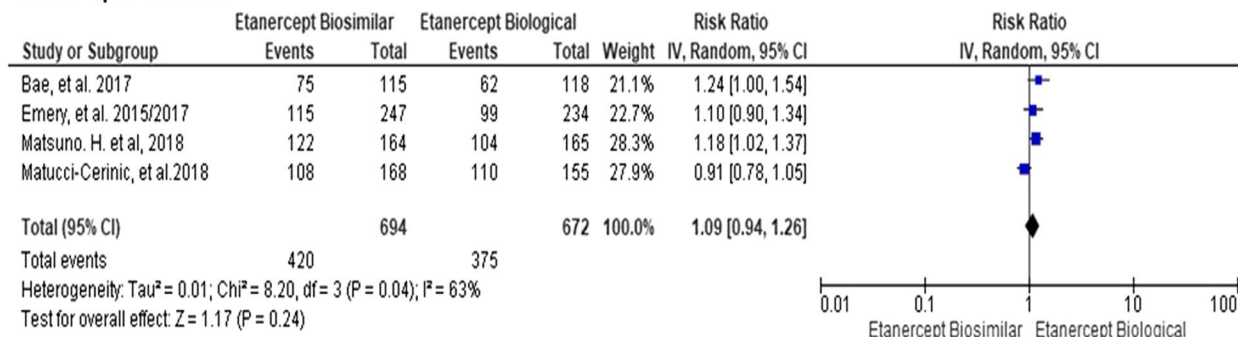

Regarding safety, Tweehuysen et al. [34] and Glinborg et al. [35] reported that the use of the biosimilar did not have a negative impact on RA disease activity, a finding that is similar to the results of this study, in which most AEs were mild or moderate in severity [36]. However, in this review, urinary tract infection (UTI) and an increase in alanine aminotransferase (ALT) are notable AEs because they were not present in analyses above 6 months. These differences were also identified for another anti-TNF biological drug certolizumab; however, more studies are needed to evaluate other clinical comorbidities not associated with the drug [37].

Some AEs were only present in the analyses above 6 months, for example, cough, upper respiratory tract infection (URTI), erythema at the injection site, and rash at the injection site. In this regard, Hans-Peter et al. [38] reported that infections that cause AEs are very common after the use of biologic ETN. I Greenblatt et al. [39] reported that AEs associated with intramuscular injections affect blood vessels, nerves, and muscles. However, these AEs can be minimized through the knowledge and skills of patients; thus, it is necessary for guidelines and

ACR 20 up to 6 months

training to be provided to patients who self-administer etanercept injections.

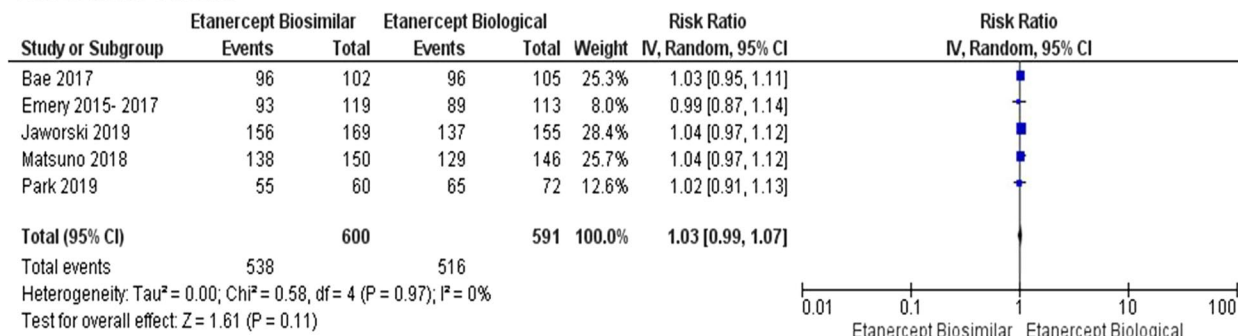

The low incidences of ADAs and positive neutralizing antibody reactions after the administration of biosimilars are consistent with immunogenicity results for patients with RA in other studies [34, 36, 40–43]. In fact, there are product-specific factors that affect immunogenicity, such as the original nature of the product (synthetic or human), impurities, product aggregates, formulation, glycosylation, and container closure system [44–50].

The study by Tweehuysen et al. [34] found that the biosimilar etanercept SB4 was less immunogenic than the reference biologic. However, it is necessary to investigate

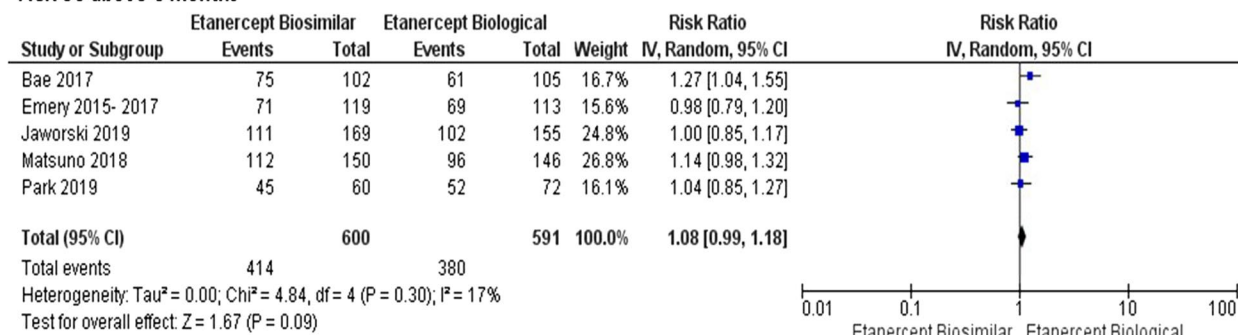

in future studies the factors that contribute to the lower immunogenicity profile of SB4.

MTX was an important synthetic DMARD used in select clinical studies because when associated with biosimilar or biologic drugs, etanercept in first-line therapy achieved satisfactory clinical responses for safety and efficacy. Vollenhoven et al. [51] reported that MTX monotherapy generated only 20 to 40% clinical improvement in patients with moderate to severe RA. In this sense, combinations of biosimilar drugs and DMARDs may be valid strategies in patients with RA who show an unsatisfactory response to the strict use of synthetic or biological DMARDs [7].

ACR 20 above 6 months

ACR 50 above 6 months

ACR 70 above 6 months

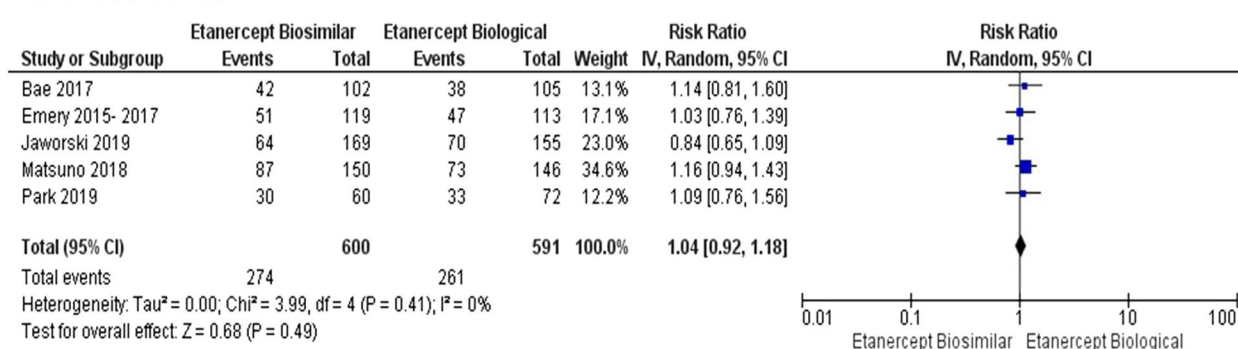

Fig. 4 Meta-analyses of ACR20, ACR50, and ACR70 above 6 months. Source: Prepared by the authors

The growing evidence of the lack of statistical significance for many of the efficacy and safety outcomes of etanercept biosimilars compared to the biologic ETN raises an alert regarding statistical analysis. In half of the individual studies, sample size calculation methods were not reported [19, 25, 26]; among those that did report, two were based on predefined criteria for power and effect size [23, 25], and one study determined sample size using historical data for equivalence testing [20]. Conversely, more than half (83.33%) of the studies described statistical power (2 studies at 80% [19, 20] and 3 studies at 90% [23–25]) as well as the adequacy of this power to

detect the expected effect sizes. It is essential to note that when studies have low statistical power, they are more likely to produce imprecise estimates or false-negative results, failing to detect an effect when it truly exists. This occurs because statistical power is influenced by several factors, including sample size, event rate in dichotomous outcomes, and data variability in continuous outcomes.

It is noteworthy that, in this study, the introduction of biosimilars can contribute to a substantial reduction in the costs of biological treatments, without compromising the quality of care offered to patients with RA [52]. This also contributes to the continued monitoring of the

long-term efficacy and safety of biosimilars through post-marketing studies and patient registries, as well as to the acceptance and confidence of health professionals and patients in biosimilars in their successful integration into therapeutic regimens, having significant implications for clinical practice and the incorporation of health policy [7].

Limitations

Some limitations were identified in this systematic review with meta-analysis: (1) the low number of primary multicenter phase III RCTs comparing biosimilars with biologic etanercept; (2) inconsistency of evidence due to high heterogeneity in some outcomes; (3) variability in the follow-up time of outcomes above 6 months; (4) absence of blinding in the switching studies; and (5) the lack of subgroup analyses in different ethnic populations worldwide.

Implications for research and clinical practice

The introduction of biosimilars may allow the pharmaceutical market to further reduce healthcare costs due to greater discounts [52]. Furthermore, health education and communication strategies positively influence patients' expectations about the transition to a biosimilar, resulting in better acceptance rates due to the attribution of drug effects [34].

In light of the uncertainty regarding the real-world similarity of biosimilars, the results of this review are consistent with previous findings: the use of biosimilars or biologics does not have a significant impact on efficacy, safety, or immunogenicity [40]. More RCTs should be performed to identify different clinical indications for the treatment of RA, with a larger sample to confirm the real long-term efficacy, safety, and immunogenicity.

Conclusions

This is the first systematic review with meta-analysis that evaluated the efficacy, safety, and immunogenicity of biosimilars with those for biologic etanercept; it is an innovative study because it measures associations in phase III RCTs that have high scientific evidence.

No unexpected or new events were observed during the study. The long-term administration of biosimilars was associated with continued efficacy and was well tolerated in patients with RA. Furthermore, treatment with a biosimilar not only improves the clinical outcomes but also the functional outcomes of patients with RA. This study found evidence that biosimilars have safety, efficacy, and immunogenicity similar to those for the reference biologic. Surveillance and post-sale registration studies are necessary to monitor the efficacy and safety of biosimilars consumed in the long term and in different regions and ethnic populations under treatment.

Supplementary Information

The online version contains supplementary material available at <https://doi.org/10.1186/s13643-024-02715-w>.

Acknowledgements

Evidence Program for Health Policies and Technologies (PEPTS) Oswaldo Cruz Foundation (Fiocruz) Brasília and the Department of Pharmaceutical Assistance of the Ministry of Health of Brazil.

Authors' contributions

AMA and JMG performed the search, removed duplicate articles, read the titles and abstracts of the articles, extracted data, and independently assessed the risks of bias. DCRP acted as a third researcher to resolve discrepancies in the selection of studies and guided the study process. JRB participated in the extraction of data from the selected studies and resolved discrepancies in the data extraction performed by the other two researchers (AMA and JMG). ETS resolved divergences in the assessment of the risks of bias and provided guidance on the use of the necessary research tools. All authors read and approved the final version of the manuscript.

Funding

AMA, JMG, and JRB were funded by the project GERE 003 FIO 18-Subproject 1 (Qualification of the Capacity for Governance and Management of Pharmaceutical Assistance within the SUS) through the Department of Pharmaceutical Assistance of the Ministry of Health and Fiocruz Brasília.

Data availability

All data generated or analyzed during this study are included in this article, together with its supplementary information file (Supplementary material 1).

Declarations

Ethics approval and consent to participate

This study is a systematic review and was registered on the PROSPERO platform under the number CRD42020166610.
