Received 25 October 1991/Accepted 1 March 1992

The ribosome protection type of tetracycline resistance (Tc^r) has been found in a variety of bacterial species, but the only two classes described previously, Tet(M) and Tet(O), shared a high degree of amino acid sequence identity (>75%). Thus, it appeared that this type of resistance emerged recently in evolution and spread among different species of bacteria by horizontal transmission. We obtained the DNA sequence of a Tc^r gene from *Bacteroides*, a genus of gram-negative, obligately anaerobic bacteria that is phylogenetically distant from the diverse species in which tet(M) and tet(O) have been found. The *Bacteroides* Tc^r gene defines a new class of ribosome protection resistance genes, Tet(Q), and has a deduced amino acid sequence that was only 40% identical to Tet(M) or Tet(O). Like tet(M) and tet(O), tet(Q) appears to have spread by horizontal transmission, but only within the *Bacteroides* group.

Bacteroides species are significant opportunistic pathogens of humans (8), and many clinical isolates of *Bacteroides* are now resistant to tetracycline. Recently, a 2.7-kb *SstI* fragment carrying a tetracycline resistance (Tc^r) gene was cloned from the *Bacteroides thetaiotaomicron* clinical isolate DOT (38, 44). The cloned gene appeared to be the only Tc^r gene in the strain of origin because a gene disruption made by using the 0.9-kb *EcoRI-EcoRV* fragment, which is shown in the present report to be internal to the Tc^r gene, made the strain susceptible to tetracycline (44).

There are three known types of tetracycline resistance mechanisms: tetracycline efflux, ribosome protection, and tetracycline modification (21, 36). Of these, the ribosome protection type of resistance appears to be the most widespread in nature. It has been found in a variety of bacteria including mycoplasmas and gram-positive and gram-negative organisms, whereas the efflux type of resistance seems to be limited mainly to members of the family *Enterobacteriaceae* and other γ -purple bacteria and to several species of gram-positive bacteria. Tetracycline modification has been found only in two strains of the obligately anaerobic genus *Bacteroides* and is an anomaly because it does not confer tetracycline resistance in *Bacteroides* species and functions as a resistance mechanism only in *Escherichia coli* strains grown under aerobic conditions (43).

Tc^r genes are classified on the basis of DNA hybridization. Two genes fall into the same Tc^r class if they cross-hybridize by Southern blot analysis under conditions of high stringency. Many classes of tetracycline efflux genes have been found, but only two classes of ribosome protection resistance genes, tet(M) and tet(O), have been defined previously (1, 22, 42). Here we report that the Tc^r in *Bacteroides* species is of the ribosome protection type.

Several representatives of tet(M) and tet(O) have been sequenced (19, 22, 24, 26, 38, 42), and the deduced amino acid sequences share a remarkable degree of identity. Members of the Tet(M) class share 92 to 97% amino acid sequence identity, and members of the Tet(O) class share 98% identity. Amino acid sequence identity between members of Tet(M) and Tet(O) is also high (75 to 77%). These similarities seemed to indicate not only that tet(M) and tet(O) are spread by horizontal transmission but also that the ribosome protection type of resistance gene appeared relatively recently in evolution. It has been proposed that tet(O) originated in gram-positive bacteria and has spread horizontally to gram-negative bacteria (42).

Although tet(M) and tet(O) have been found in a variety of gram-negative and gram-positive bacteria, bacterial genera of these types do not represent the full range of phylogenetic diversity seen in the bacteria. Thus, the apparent homogeneity of ribosomal protection Tc^r genes could be due in part to an incomplete sampling of bacterial isolates. Since Bacteroides species are phylogenetically distant from the organisms in which tet(M) and tet(O) have been found, it was possible that other extant classes of ribosome protection Tcr genes might be found in this genus. Here we report the DNA sequence and characteristics of a Bacteroides Tcr gene. We report that although this Bacteroides resistance gene shares some amino acid identity with Tet(M) and Tet(O), it is much more distantly related to these proteins than the proteins are to each other. We designated this new ribosome protection tetracycline resistance gene tet(Q).

MATERIALS AND METHODS

Bacterial strains, plasmids, and growth conditions. Unless otherwise indicated, all experiments involving Bacteroides species were done with B. thetaiotaomicron BT4001, a spontaneous Rif^T derivative of the *B. thetaiotaomicron* type strain 5482 (Tc^s [16]). The following strains were used in a survey in which the genomic DNAs of Bacteroides isolates were screened by Southern blotting for hybridization to the internal EcoRI-EcoRV fragment from the cloned tet(Q)gene: B. caccae 8608 and B. thetaiotaomicron 2808, Tcr clinical isolates (16); B. distasonis C30-45, B. distasonis 6308, B. uniformis 3537, B. uniformis T1-1 (16), and B. uniformis C7-17 (15), Tc^r fecal isolates; B. distasonis 6779 (Tcr), B. distasonis 6781 (Tcr Apr), B. fragilis 8371 (Tcr Emr), B. ovatus 7991 (Tcr Emr), B. thetaiotaomicron 7853 (Tcr Em^r), B. thetaiotaomicron 8702 (Tc^r), and B. vulgatus 8526 (Tc^r Ap^r), clinical isolates that were provided by Colin Getty, Wadsworth Veterans Administration Hospital, Los Angeles, Calif.; and B. fragilis AK87, a Tcr clinical isolate

^{*} Corresponding author.

which was provided by A. Kuritza, Yale University Medical School, New Haven, Conn. Also included in the survey were the following B. thetaiotaomicron BT4001 transconjugants from different Tcr clinical isolates carrying self-transmissible chromosomal elements: B. thetaiotaomicron BT4002 (Tcr transconjugant from B. fragilis V479 [40]), B. thetaiotaomicron BT4003 (Tcr Emr transconjugant from B. fragilis CEST), B. thetaiotaomicron BT4004 (Tcr Emr transconjugant from B. fragilis ERL [40]), B. thetaiotaomicron BT4005 (Tcr transconjugant from B. fragilis Tcr Emr ERL), B. thetaiotaomicron BT4007 (Tcr Emr transconjugant from B. thetaiotaomicron DOT2 [40]), and B. thetaiotaomicron BT4008 (Tcr Emr transconjugant from B. fragilis 12256 [40]). B. caccae 3452A, B. distasonis 4243, and B. thetaiotaomicron 5482 are Tc^s Em^s type strains (16) that were used as controls. B. thetaiotaomicron BT4001 and B. uniformis BU1001 (Tc^s Em^s; Rif^r derivative of *B. uniformis* 0061 [39]) were also used as controls.

The plasmids used and constructed in this study were based on pFD160, a pUC19-pB1143 chimeric shuttle vector (41). *Bacteroides* strains were grown either in prereduced Trypticase (BBL Microbiology Systems)-yeast extract-glucose (TYG [15]) under an 80% N₂-20% CO₂ atmosphere or on TYG agar plates in a GasPak jar. For most experiments involving *E. coli*, the strain used was *E. coli* DH5 α (Tc^s [13]). For maxicell experiments, *E. coli* LCD44 (RecA MetE Tc^s) was used (5). *E. coli* strains were grown in Luria broth (LB) or on LB agar plates unless otherwise indicated.

Plasmids were introduced into *E. coli* by the method of Lederberg and Cohen (20). To test plasmids for Tc^r expression in *B. thetaiotaomicron*, constructs were mobilized from *E. coli* as described previously (39). Since transfer frequencies were several log units above the background, failure to attain a Tc^r transconjugant was a reasonable indication that a construct failed to express Tc^r .

DNA isolation and analysis. Plasmids were isolated from E. coli or Bacteroides species by the Ish-Horowitz modification of the procedure of Birnboim and Doly (23). Chromosomal DNAs from Bacteroides species were isolated by the method of Saito and Miura (34). Restriction digests and ligation with T4 DNA ligase were done by standard procedures (23). Electrophoretic resolution of restriction digests was done in 0.8 to 1.0% agarose slab gels in $1 \times$ or $4 \times$ GGB ($1 \times$ GGB is 0.04 M Tris, 0.02 M sodium acetate, and 0.002 M EDTA). For Southern hybridization experiments, Bacteroides chromosomal DNA was digested with both EcoRI and EcoRV, electrophoresed on a 1% agarose gel, and capillary blotted (23) onto a polyester-reinforced nitrocellulose membrane (Schleicher & Schuell, Keene, N.H.). The probe, the internal 0.9-kb EcoRI-EcoRV fragment from tet(Q), was labeled by nick translation with $[\alpha^{-32}P]dCTP$ (800 Ci/mmol [29]). The high-stringency hybridization and wash conditions have been described previously (39). Low-stringency hybridization conditions were the same as those for high-stringency hybridization, except that the hybridization solution did not contain formamide and blots were washed at 25°C. Blots of genomic digests of strains containing the cloned Bacteroides Tc^r gene were probed under low-stringency conditions with ³²P-labeled pAM120 (9) to test the similarity of the Tc^r gene to tet(M) gene from the streptococcal Tn916.

MIC of tetracycline. In most experiments in which *E. coli* was used as the host, MICs were attained by LB broth dilution to serial increments of 5 μ g of tetracycline per ml by using a final inoculum of 10⁷ CFU/ml (subculture volume, 0.1 ml). Visible growth was scored after 12 and 24 h of incubation at 37°C. In one experiment, the tetracycline MIC was

determined by streaking the *E. coli* host onto LB agar plates containing 5- μ g/ml increments of tetracycline. Growth was scored after 24 and 48 h of incubation at 37°C. When a *Bacteroides* species was the host, MICs were determined by broth dilution in TYG broth with serial increments of 5 μ g of tetracycline per ml by using a final inoculum of 10⁷ CFU/ml. Growth was scored after 24 h of incubation at 37°C.

Analysis of the proteins expressed from the clone. The maxicell procedure was executed as described by Sancar et al. (37), with *E. coli* LCD44 used as the host. Maxicell fractionation was performed by an adaptation of the method of Tai and Kaplan (45). In some experiments, proteins expressed from the cloned segment were detected by using an *E. coli*-derived in vitro transcription-translation system (7) in kit form (Amersham, Arlington Heights, Ill.). In both cases, proteins were solubilized in sodium dodecyl sulfate (SDS) at 37°C and were then resolved on highly cross-linked 11% SDS-polyacrylamide gels.

DNA sequencing and analysis. Progressive unidirectional deletions were introduced into the cloned 2.7-kb SstI fragment by an adaptation of the exonuclease III procedure of Henikoff (14) in kit form (Erase-a-Base system; Promega, Madison, Wis.). Both strands were sequenced by the dideoxy-chain termination reaction with the T7 DNA polymerase variant and reagents provided in the Sequenase 2.0 kit (U.S. Biochemicals, Cleveland, Ohio). Computer analysis of nucleotide and amino acid sequences was performed by using Genetics Computer Group software (6) on a MicroVAX system. Pairwise comparisons of sequences were made by using the GAP program. The GAP program uses the algorithm of Needleman and Wunsch to align sequences (25). Sequence similarity searches were done by using the FASTA program (28). The sequences that were compared and used to construct the amino acid alignment for this study were tet(M) from Staphylococcus aureus (GenBank accession number M21136), Streptococcus faecalis (GenBank accession number X04388), and Ureaplasma urealyticum (GenBank accession number X06901) and tet(O) from Campylobacter jejuni (GenBank accession number M18896) and Streptococcus mutans (GenBank accession number M20925).

Nucleotide sequence accession number. The full DNA sequence of the 2.7-kb *SstI* fragment has been deposited in the EMBL Data Library (accession number X58717).

RESULTS

Characteristics of the *Bacteroides* **Tc**^r **gene product.** Both orientations of the cloned *SstI* fragment (pNFD13-2 and pNFD13-6; Fig. 1) conferred resistance in *Bacteroides* species. The MIC of tetracycline for *B. thetaiotaomicron* bearing pNFD13-2 in broth cultures was 80 μ g/ml. *Bacteroides* strains lacking Tc^r did not grow in 2 μ g of tetracycline per ml.

Previous experience with *Bacteroides* antibiotic resistance genes indicated that these genes are not expressed in *E. coli* (11, 36, 50). Nevertheless, both clones of the *B. thetaiotaomicron* DOT Tc^r gene, pNFD13-2 and pNFD13-6, conferred Tc^r in *E. coli* DH5 α . The MIC was 40 to 50 µg/ml when the MIC was determined with broth cultures. If susceptibility was determined by using LB agar plates, the MIC was much lower (10 µg/ml). The fact that the *Bacteroides* gene was expressed in *E. coli* allowed us to localize the gene and characterize the gene product using techniques developed for use in *E. coli*.

Deletions into the leftward EcoRV site (pNFD13-

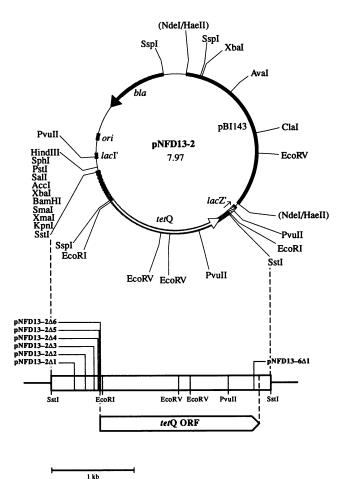

FIG. 1. Partial restriction map of pNFD13-2 showing the 2.7-kb SstI insertion into the SstI site of pFD160. pNFD13-6 (not shown) has the same insert but in the opposite orientation. The endpoints of important deletion derivatives are indicated by the labeled brackets. The orientation and extent of the large open reading frame (ORF) encoding Tet(Q) are indicated below by the arrow.

 $2\Delta E co RV$) or to the EcoRI site (pNFD13-2 $\Delta E co RI$) abolished resistance, indicating that the Tcr gene spans the 0.9-kb EcoRV-EcoRI segment (Fig. 1). The gene was further localized by making unidirectional exonuclease III deletions in the insert DNA. When the deletions were tested in E. coli, pNFD13-2 Δ 1, pNFD13-2 Δ 2, and pNFD13-2 Δ 3, which were deletions ending 0.3, 0.2, and 0.1 kb, respectively, from the left of the EcoRI site, did not affect the level of resistance. pNFD13-2 Δ 4, which extended to within 0.1 kb of the *Eco*RI site, reduced the level of resistance but did not eliminate it completely. pNFD13-2 Δ 5, which also extended to within 0.1 kb of the EcoRI site and beyond the endpoint of pNFD13- $2\Delta 4$, abolished resistance. Deletions beyond the *Eco*RI site, such as pNFD13-2 Δ 6, also eliminated resistance. The smallest deletion from the right, pNFD13-6 Δ 1, extended 0.2 kb from the right end of the cloned fragment and eliminated resistance. Thus, approximately 2.1 kb of DNA was required in order to express Tc^r in E. coli. A slightly larger segment was needed to confer resistance in Bacteroides species. The largest deletion that conferred resistance in Bacteroides species was pNFD13-2 Δ 2.

In *E. coli* maxicells, two proteins which were not expressed from the base vector pFD160 were strongly ex-

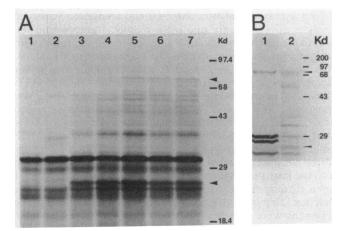

FIG. 2. Products of the 2.7-kb SstI clone in E. coli. (A) Autoradiogram of an SDS-polyacrylamide gel of in vitro transcriptiontranslation products. Lane 1, products from the vector control pFD160. Shown also are products from Tc^s deletion derivatives pNFD13-2 ΔEco RV (lane 2) and pNFD13-2 $\Delta 5$ (lane 3), reduced Tc^r deletion derivative pNFD13-2 $\Delta 4$ (lane 4), Tc^r deletion derivatives pNFD13-2 $\Delta 3$ (lane 5) and pNFD13-2 $\Delta 1$ (lane 6), and intact pNFD13-2 (lane 7). The arrowheads in the right margin mark the two bands that were consistently unique to the SstI clone in maxicells. (B) Autoradiogram of soluble and membrane fractions from maxicells containing pNFD13-2. Lane 1, soluble fraction; lane 2, membrane fraction. Kd, kilodaltons.

pressed from pNFD13-2. These were estimated to have molecular masses of 76 and 25.5 kDa (data not shown). Both of these proteins, along with additional proteins not seen in the maxicells, were seen when pNFD13-2 or its deletion derivatives were used as templates in an in vitro transcription-translation system (Fig. 2A). The presence of the 76kDa protein coincided with resistance. In contrast, the 25.5-kDa protein and the other proteins were still produced from the Tc^s deletion template, pNFD13-2 Δ 5 (Fig. 2A, lane 3). Also, although the 76-kDa protein was produced from pNFD13-6, the reverse orientation clone, the 25.5-kDa protein was not apparent (data not shown). In *E. coli* maxicells, the 76-kDa protein partitioned predominantly with the soluble fraction (Fig. 2B).

Distribution of the cloned Tcr gene among Bacteroides species. Resistance to tetracycline has been reported to be widespread in human colonic Bacteroides species (46). To determine whether the Tc^r gene cloned in pNFD13-2 was the predominant type of resistance in the colonic Bacteroides species, 21 Tc^r clinical isolates and 5 Tc^s strains were screened for hybridization with the EcoRV-EcoRI internal segment on Southern blots of genomic DNA digested with EcoRV and EcoRI. These strains represented a variety of Bacteroides species from a variety of sources and geographic locations. All of the Tc^r strains but none of the Tc^s strains tested hybridized with the internal fragment from the Tc^r gene on pNFD13-2. All but one Tc^r strain had a hybridizing band that was the same size as the probe fragment (0.9 kb). Of these, the EcoRI-EcoRV chromosomal band from B. thetaiotaomicron BT4002 exhibited weaker hybridization to the probe than was seen with DNA from the other Tcr strains. The one strain which did not yield a 0.9-kb hybridizing band was B. distasonis C30-45; instead, a 19-kb EcoRI-EcoRV genomic band hybridized with the probe.

DNA sequence of the Tc^r gene. The DNA sequence of the

2.7-kb SstI fragment was obtained and analyzed. Sequence analysis revealed only one open reading frame within the SstI clone that was sufficiently large to encode a protein with an approximate size of 76 kDa. This open reading frame had two possible start sites, since it is not known whether Bacteroides species initiates translation at GTG or ATG sites. An open reading frame beginning at an ATG site (position 586 of the DNA sequence) coded for 642 amino acids, while a larger open reading frame beginning at a GTG start site (position 538 of the DNA sequence) coded for 658 amino acids. However, pNFD13-2 Δ 4, a deletion which conferred a reduced level of resistance in E. coli, extended 26 bp into the larger open reading frame. The extent of the smaller open reading frame correlated well with the results of the deletion analysis. All other open reading frames in the fragment were less than 400 bp in length. A partial open reading frame started within the stop codon of the large open reading frame and extended to the end of the cloned segment. This open reading frame may have created a fusion that was responsible for the 25.5-kDa protein seen in the maxicells and the in vitro system.

The deduced amino acid sequence of the large open reading is shown in Fig. 3. The open reading frame encoded a protein of 642 amino acids (deduced molecular mass, 72,100 Da). The DNA sequence had a 40.1 mol% G+C content, in comparison with a 42 mol% G+C content for chromosomal DNA from *B. thetaiotaomicron*, the species of origin. Values for colonic *Bacteroides* species vary from 39 to 46 mol% G+C (16).

Similarity to previously studied Tc^r genes. FASTA searches of the GenBank and EMBL data bases chose representatives of tet(M) and tet(O) as the most similar relatives to the *Bacteroides* Tc^r gene. There was no significant similarity between the *Bacteroides* Tc^r gene and any of the efflux classes of resistance genes or the tetracycline modification type resistance gene tet(X).

On Southern blots under conditions of low stringency, a tet(M) probe from Tn916 did not hybridize with genomic DNA from *Bacteroides* strains harboring tet(Q). These results indicated that the *Bacteroides* Tc^r is not highly similar to tet(M) or tet(O), since genes from these classes have been reported to cross-hybridize under conditions of low stringency (42, 47, 49). DNA sequence comparisons of tet(Q) and examples of tet(M) and tet(O) yielded identity values of 51.5 to 52.6%. When they were compared by using the same program, tet(M) and tet(O) were 75.2 to 75.7% identical. Restriction maps of the sequenced tet(M)- and tet(O)-coding sequences were generated. Only tet(M) of *S. aureus* contained either an *Eco*RV site near its downstream end.

The size of the deduced Bacteroides Tcr protein (642 amino acids) was similar to the sizes of proteins encoded by tet(M) and tet(O), which ranged from 638 to 640 amino acids in length. When the amino acid sequence of Tet(Q) was aligned with Tet(M) and Tet(O), seven short regions of length variation were evident (Fig. 3). One of these regions was the carboxy-terminal part of the alignment, which also varied in Tet(O) of C. jejuni in comparison with other Tet(M) and Tet(O) sequences. Comparison of the deduced amino acid sequence of the Bacteroides Tcr gene with those of the tet(M) and tet(O) genes demonstrated that the Bacteroides Tc^r gene was related to, but distinct from, those genes (Table 1). Since the Bacteroides Tc^r appeared to be a ribosome protection type of resistance, we designated the gene tet(Q), because the designations tet(N) and tet(P) have already been used (36).

DISCUSSION

In human colonic *Bacteroides* species, Tc^r genes are generally found in the chromosome on large (65- to 75-kb), self-transmissible elements rather than on plasmids (27, 35). It is likely that these elements are responsible for the spread of tetracycline resistance within the genus *Bacteroides*. The Tc^r gene described in this report was cloned from a strain containing one of the chromosomal Tc^r elements.

An internal *Eco*RI-*Eco*RV fragment from the cloned tet(Q) gene cross-hybridized under conditions of high stringency in Southern blots with DNA fragments of the same size from other human colonic *Bacteroides* Tc^r isolates. Since the different *Bacteroides* species in which this Tc^r gene was found share total DNA-DNA homologies of less than 45%, and in some cases less than 7% (16), results of the Southern analysis indicate that the *Bacteroides* Tc^r gene, tet(Q), has spread by horizontal transmission among the *Bacteroides* species, just as tet(M) and tet(O) have spread among diverse gram-positive and gram-negative bacteria. This evidence also suggests that tet(Q) is the predominant Tc^r determinant in the colonic *Bacteroides* species.

Recently, Guiney and Bouic (10) demonstrated that Tc^r strains of oral *Bacteroides* species have DNAs which crosshybridize on Southern blots with DNAs of colonic strains containing Tc^r elements. Thus, tet(Q) appears to be widespread within diverse groups of the genus *Bacteroides*.

Most of the bacteria in which tet(M), tet(O), and tet(Q)have been found are human clinical isolates. Thus, it seems likely that horizontal transfer of these genes occurs in human hosts. Nevertheless, the tet(Q) class seems to have remained in the Bacteroides group and the tet(M) and tet(O) classes have remained in a separate group of bacteria which includes some gram-positive and some gram-negative species (Fig. 4). Recently, the first possible exception to this segregation has been reported. Chromosomal DNA from two isolates of B. ureolyticus was reported to hybridize with a tet(M) probe under conditions in which high salt concentrations were used (4). Given the degree of dissimilarity of the DNA sequences of tet(Q) and tet(M), it is unlikely that tet(Q) would hybridize with the tet(M) probe under the conditions used in that study. However, tet(O) might hybridize with tet(M) under those conditions. These findings could mean that the tet(M)and tet(O) resistances have entered the Bacteroides group. However, superficially similar groups have often been misclassified as Bacteroides species in the past. The precise taxonomy of B. ureolyticus remains unclear.

Bacteroides chromosomal elements can mobilize coresident plasmids into E. coli (51), but transfer of the elements themselves to species outside of the Bacteroides group has not been reported. An effective barrier to horizontal transfer may exist between the Bacteroides group and the group of species in which tet(M) and tet(O) resistances are spread. This barrier could be due either to failure of the conjugal elements to insert in the recipient chromosome or to failure of the Tc^r gene on the element to be expressed effectively. However, further screening of clinical isolates may provide examples of tet(M) and tet(O) resistances in the Bacteroides group or of tet(Q) in species outside the Bacteroides group.

The degree of dissimilarity between the amino acid sequence of Tet(Q) and those of Tet(M) and Tet(O) illustrated in Table 1 provides new information about regions that may be important for ribosome protection Tc^r function. The regions with the highest amino acid identity were amino acids 1 to 134 (57% identity) and 434 to 546 (55% identity) of the alignment shown in Fig. 3. The conservation at the amino

FIG. 3. Deduced amino acid sequence of Tet(Q) aligned with representatives of Tet(O) (*C. jejuni* [Caj] [22]) and Tet(M) (*S. faecalis* [Stp] [24]) (Bat, *B. thetaiotaomicron*). The consensus of the sequenced ribosomal protection Tc^r genes is displayed below these sequences. Capital letters denote conservation among the ribosome protection Tc^r proteins. The four regions of conservation in GTP-binding proteins are indicated by overbars (12). Positions marked with an asterisk were found to be involved directly in GTP binding and are invariant in all GTP-binding proteins (17).

	Percent similarity or identity ^a							
Organism	S. aureus Tet(M)	S. faecalis Tet(M)	U. urealyticum Tet(M)	C. jejuni Tet(O)	S. mutans Tet(O)	B. thetaiotaomicron Tet(Q)		
S. aureus Tet(M)		95.3	98.1	85.3	85.9	62.8		
S. faecalis Tet(M)	92.2		96.7	85.7	86.1	61.1		
U. urealyticum Tet(M)	96.6	95.0		85.7	86.3	62.5		
C. jejuni Tet(O)	75.1	76.8	76.0		98.4	60.5		
S. mutans Tet(O)	75.6	76.9	76.4	98.1		60.8		
B. thetaiotaomicron Tet(Q)	41.2	41.0	41.2	41.0	41.0			

TABLE 1. Similarity matrix for the deduced amino acid sequences of sequenced ribosome protection tetracycline resistance genes

^a Percentage of similar amino acids in the generated sequence alignment are given above the blank space, and percentage of matching amino acids in the generated sequence alignment are given below the blank space.

terminus was particularly evident in the regions thought to be important for GTP binding. It seems likely that Tet(Q)possesses ribosome-dependent GTPase activity similar to those exhibited by Tet(M) and EF-G (2). The conservation in amino acids 434 to 546 indicates that this region probably has some important function as well.

Although tet(Q) is similar enough to the tet(M) and tet(O)group of ribosome protection Tc^r genes to be considered a member of this gene family, it is different enough from tet(M)and tet(O) to form a new Tc^r class. The existence of tet(Q) as

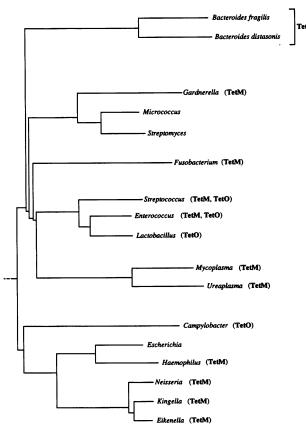

FIG. 4. Distance tree based on 16S rRNA sequences of bacteria that are known to carry ribosome protection Tc^r determinants. The determinant(s) known to be carried by representatives of a genus are indicated in bold (3, 18, 30–33, 38, 48, 52). Some bacteria that carry ribosome protection type resistances were omitted because their 16S rRNA sequences are not available.

the outlying class of the ribosome protection type Tc^r genes indicates that this family of genes contains more divergence than appeared to be the case when only tet(M) and tet(O)were known. This divergence implies that the ribosome protection type of Tc^r may be more ancient than was previously thought. It also raises the question of whether other classes of ribosome protection Tc^r genes remain to be found.

ACKNOWLEDGMENTS

We thank Jeff Smith for providing pFD160 and Gary Olsen for helping to assemble the 16S rRNA tree shown in Fig. 4.

This work was supported by Public Health Service grant AI22383 from the National Institute of Allergy and Infectious Diseases.

ADDENDUM

While the manuscript was in review, a new ribosome protection type determinant for oxytetracycline resistance from *Streptomyces rimosus*, otr(A), was described (D. Doyle, K. J. McDowall, M. J. Butler, and I. S. Hunter, Mol. Microbiol. **5**:2923–2933, 1991). The otr(A) DNA sequence (EMBL/GenBank accession X53401) was 40.6 to 41.2% identical to tet(M) sequences, 43.3% identical to tet(O) sequences, and 44.0% identical to the tet(Q) sequence when they were compared as described above. By deduced amino acid sequence comparison, Otr(A) was 32.5 to 33.0% identical to Tet(M) sequences, 34.5% identical to Tet(O) sequences, and 32.3% identical to Tet(Q) sequences. The fact that otr(A) is so different from the other ribosome protection type resistances, including tet(Q), further demonstrates the diversity of this group of genes and indicates that the group may have a relatively early evolutionary origin.
