### Abstract

Substitutions on the 2-position of the imidazole ring of histamine have proven useful in a number of biochemical settings. Current art for the synthesis of these constructs relies upon a cumbersome and low-yielding condensation reaction. Here-in we report a new procedure for the synthesis of a series of substituted 2-phenylhistamines utilizing a microwave-promoted Suzuki coupling.

### Keywords

heteroaromatic Suzuki coupling; microwave promoted Suzuki coupling; 2-phenylhistamine

The utility of histamine analogues in various biochemical settings is firmly established. Derivatives of histamine based upon alterations to the 2-aminoethyl side chain have been employed as substrates for histamine *N*-methyltransferase and as antagonists of the H<sub>1</sub>-receptor.<sup>1,2</sup> Methyl substitution at the 4 position of histamine generates a potent agonist of the histamine H<sub>4</sub>-receptor.<sup>3</sup> Substitutions at the 2 position of histamine have been widely explored both synthetically and biochemically, primarily as pharmacological tools for the histamine receptors. Of particular interest has been the use of 2-phenylhistamines as potent agonists of the H<sub>1</sub>-receptor.<sup>4,5</sup> Recent efforts by Leurs and coworkers have identified 2-(3-trifluoromethyl)phenylhistamine (**3a**) as the sole agonist of a mutant form of the histamine H<sub>1</sub>-receptor.<sup>6</sup> This combination of a synthetic ligand and mutant receptor provides researchers with a tool to study the relationship between function and phenotype of a cellular target free of the selectivity issues which plague studies utilizing the native ligand and unaltered protein.

Modified native ligands such as the aforementioned histamine analogues have proven to be among the most frequently explored pharmacological tools. A key to this strategy is the ability to quickly explore numerous alterations and structural sub-types to ascertain the effectiveness of these constructs in a variety of biochemical settings. It is imperative that the strategies employed to construct these compounds are appropriately convergent to maximize synthetic efficiency. The full understanding of the biochemical utility of substituted 2-phenylhistamine analogues is likely unknown given the limited number of analogues explored to date. The synthesis of substituted 2-phenylhistamines has relied upon a condensation between amidines/imidates and 2-oxo-4-phthalimido-1-butyl acetate to afford phthalimide protected histamine analogues.<sup>5,7</sup> Thus, a separate syntheses of substituted amidines or imidates are required for

individual substituted 2-phenylhistamine analogues. Recognizing the biochemical utility of these constructs and the need for efficient methods to generate larger numbers of related analogues, we sought out alternate synthetic methods.

The utility of palladium-catalyzed cross coupling reactions has evolved to become a major foundation by which new carbon-carbon bonds are formed.<sup>8</sup> The inclusion of microwave heating has aided the speed and efficiency of these transformations, particularly in the case of aryl-aryl Suzuki couplings.<sup>9</sup> It was our goal to develop a synthetic method for the formation of substituted 2-phenylhistamines utilizing a microwave-promoted Suzuki coupling between substituted phenyl boronic acids and a common 2-halohistamine derivative. Suzuki couplings between halo-heteroaromatic constructs and aryl-boronic acids are frequently reported and successful examples include couplings between aryl-boronic acids and benzimidazoles,<sup>10</sup> imidazoles,<sup>11</sup> pyrimidines,<sup>12</sup> and oxazoles.<sup>13</sup> A method for the construction of substituted 2-phenylhistamines using this approach would allow for the rapid advancement of numerous analogues via a final stage coupling from a common precursor.

Our method relies upon the facile synthesis of a 2-halo-histamine derivative for the implementation of the final Suzuki reaction (Scheme 1). To achieve this a protocol from Cohen and coworkers<sup>14</sup> was utilized whereby Boc protected ( $\alpha$ -nitrogen) histamine was iodinated with 2.2 equivalents of *N*-iodosuccinimide to achieve *N* <sup>$\alpha$</sup> -Boc-2,4-diiodohistamine (**1**) in quantitative yield. Monoiodinations utilizing stoichiometric quantities of *N*-iodosuccinimide resulted in complex mixtures of the mono and diiodinated products. Treatment of **1** in refluxing 1N HCl for 72 hours followed by replacement of the Boc protecting group effectively yielded the necessary *N* <sup>$\alpha$</sup> -Boc-2-iodohistamine (**2**) in modest yields over two steps. This key intermediate was then subjected to Suzuki type conditions {PdCl<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub> [5 mol%] in DME for 30 minutes followed by 3 equivalents of boronic acids **4a-n** in aqueous sodium bicarbonate}.<sup>15</sup> The mixture was heated via microwave irradiation to 110 °C for 2h at which time a 4 N solution of aqueous HCl was added to the reaction mixture and microwave irradiation was continued for an additional 0.5 h. Higher temperatures with shorter reaction times resulted in decomposition of the iodohistamine and an inability to recover the coupled biaryl product. The resulting products (**3a-n**) were purified immediately (failure to immediately purify the final products was consistently detrimental to the overall yield). Table 1 describes the scope and generality of the procedure utilizing variously substituted phenyl boronic acids to yield numerous substituted 2-phenylhistamine analogues.<sup>16</sup> Yields were consistently greater than 60% for the two step, one pot synthetic procedure. Various catalysts were explored, as well as surveys of the inorganic base, solvent combinations and temperature ranges. While the results from these appraisals were not universal, the end choice of 5 mol% PdCl<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub> and aqueous sodium bicarbonate consistently gave the best results. Further, we considered the need for protection of the  $\tau$ -nitrogen and found that such attempts were detrimental to the Suzuki coupling. Protection of the  $\alpha$ -nitrogen was essential for the reaction to progress. Use of alternate protecting groups for the  $\alpha$ -nitrogen was also noted to confer unfavorable results on the procedure.

In summary, we have developed a concise, efficient and general method for the synthesis of substituted 2-phenylhistamine analogues from a common precursor.

15. **General Experimental.** All microwave reactions were performed in a Biotage 0.5–2.0 mL vessel with a crimped top. 1,2-Dimethoxyethane (DME) was used as purchased. The 4M hydrochloric acid in dimethoxyethane (HCl in DME) solution was used as purchased. The 2M aqueous sodium carbonate solution was freshly prepared for each iteration. All organic reagents were used as purchased. The catalyst, transdichlorobis(triphenylphosphine) palladium(II) [Pd(PPh<sub>3</sub>)<sub>2</sub>Cl<sub>2</sub>] was purchased from Strem Chemicals and stored in a desiccator. The products were purified via flash chromatography, using 32 – 63 μm silica gel. Methylene chloride for chromatography (CH<sub>2</sub>Cl<sub>2</sub>) was used as purchased. Saturated ammonia/methanol (CH<sub>3</sub>OH/(NH<sub>3</sub>)) was prepared by sparging methanol with ammonia gas for approx. 1 h. A Biotage Initiator 1.2 microwave was utilized for the Suzuki coupling reactions. HRMS were obtained by The Proteomics and Mass Spectrometry Facility at NIDDK/NIH/DHHS on a Waters LCT Premier time-of-flight (TOF) mass spectrometer, using the internal reference standard method. **General Procedure for Suzuki Coupling:** To a solution of *N*-tertbutylcarbonyl-2-iodohistamine (1eq) in dimethoxyethane (0.04M) was added PdCl<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub> (5 mol%). The solution was sparged with nitrogen stirred at room temperature for 0.5 h, at which time the boronic acid (3 eq) and aq. sodium carbonate (2M) were added. The reaction solution was sparged again with nitrogen and then placed in the microwave and heated for 2 h at 110 °C. When TLC and LC-MS showed full consumption of starting materials, HCl/dioxane (4M) was added and the reaction tube was again placed in the microwave and heated for 0.5 h. The crude product was directly purified by column chromatography (without additional work-up; 0–20% CH<sub>3</sub>OH(NH<sub>3</sub>)/CH<sub>2</sub>Cl<sub>2</sub>) to isolate the histamines as free bases. All products showed greater than 95% purity by LCMS analysis, however, it should be noted that each product eluted in the void volume of a 100% buffered aqueous gradient.
