All-*trans*-retinoic acid (*trans*-RA) and other retinoids exert anticancer effects through two types of retinoid receptors, the RA receptors (RARs) and retinoid X receptors (RXRs). Previous studies demonstrated that the growth-inhibitory effects of *trans*-RA and related retinoids are impaired in certain estrogen-independent breast cancer cell lines due to their lower levels of RAR α and RAR β . In this study, we evaluated several synthetic retinoids for their ability to induce growth inhibition and apoptosis in both *trans*-RA-sensitive and *trans*-RA-resistant breast cancer cell lines. Our results demonstrate that RXR-selective retinoids, particularly in combination with RAR-selective retinoids, could significantly induce RAR β and inhibit the growth and induce the apoptosis of *trans*-RA-resistant, RAR α -deficient MDA-MB-231 cells but had low activity against *trans*-RA-sensitive ZR-75-1 cells that express high levels of RAR α . Using gel retardation and transient transfection assays, we found that the effects of RXR-selective retinoids on MDA-MB-231 cells were most likely mediated by RXR-nur77 heterodimers that bound to the RA response element in the RAR β promoter and activated the RAR β promoter in response to RXR-selective retinoids. In contrast, growth inhibition by RAR-selective retinoids in *trans*-RA-sensitive, RAR α -expressing cells most probably occurred through RXR-RAR α heterodimers that also bound to and activated the RAR β promoter. In MDA-MB-231 clones stably expressing RAR α , both RAR β induction and growth inhibition by RXR-selective retinoids were suppressed, while the effects of RAR-selective retinoids were enhanced. Together, our results demonstrate that activation of RXR can inhibit the growth of *trans*-RA-resistant MDA-MB-231 breast cancer cells and suggest that low cellular RAR α may regulate the signaling switch from RAR-mediated to RXR-mediated growth inhibition in breast cancer cells.

Retinoids, the natural and synthetic vitamin A analogs, exert profound effects on cell proliferation, differentiation, and apoptosis (19, 36, 50) and are considered promising agents for the prevention and treatment of human cancers, including breast cancer (36, 43, 50). Retinoids, alone or in combination with an antiestrogen or interferons, inhibit the *in vitro* growth of human breast cancer cells (12–14, 29, 34, 51, 60–62). The natural retinoid derivative retinyl methyl ether (18) and the synthetic retinoids *N*-(4-hydroxyphenyl) retinamide (4-HPR) (44, 45) and LGD1069 (17) effectively inhibited the development of carcinogen-induced mammary cancers in animals. Unfortunately, clinical trials on patients with advanced breast cancer showed no significant activity for retinoids (2, 3, 42). These studies indicate that retinoids are effective inhibitors of the cancer cells at the early stages of tumor progression and that their effectiveness diminishes as cells become more malignant and invasive. They are also consistent with well-documented *in vitro* observations that growth inhibition by all-*trans*-retinoic acid (*trans*-RA) and related retinoids occurs mainly in estrogen-dependent, estrogen receptor-positive breast cancer cells and that upon progression to estrogen independence and loss of the estrogen receptor, most breast cancer cells become refractory to growth inhibition by *trans*-RA (14, 34, 54, 55, 60).

The effects of retinoids are mainly mediated by two classes of nuclear receptors, the RA receptors (RARs) and retinoid X receptors (RXRs) (28, 38, 70). 9-*cis*-RA is a high-affinity natural ligand for both RARs and RXRs, whereas *trans*-RA is a

high-affinity natural ligand only for the RARs. RARs and RXRs are each encoded by three distinct genes (α , β , and γ) and are members of the steroid/thyroid hormone/retinoid receptor superfamily, which function as ligand-activated transcription factors (28, 38, 70). RARs interact with RXRs, forming RXR-RAR heterodimers that bind to RA response elements (RAREs) to control the expression of RA-responsive genes in the presence of retinoids. Transcriptional regulation of RA-responsive genes is also modulated by a number of cofactors that appear to provide a direct link to the core transcriptional machinery and/or to modulate chromatin structure (reference 27 and references therein). Although RXR acts as a silent heterodimerization partner of RAR in CV-1 cells (15, 30, 38), recent studies demonstrate that binding of certain RXR ligands contributes to activation of RXR-RAR heterodimers in some cell types (4, 31, 40, 52, 59, 71). In the presence of 9-*cis*-RA, RXRs can also function as homodimers that bind a set of specific DNA sequences (68, 70, 71). Furthermore, activation of RXR is required for the function of other RXR-containing heterodimers, such as RXR-nur77 (15, 49) and RXR-LXR (63). Thus, distinct retinoid signaling pathways through activation of either RAR or RXR exist; however, the role of RXR activation in these pathways requires clarification.

RA target genes, including those for the RARs, have been identified. The RARE (β RARE) in the RAR β gene promoter mediates *trans*-RA-induced RAR β gene expression in many different cell types (10, 21, 57) and binds both RXR-RAR (28, 38, 70) and RXR-nur77 (15, 49) heterodimers. Gene transcriptional activation by RXR-RAR binding is mainly activated by RAR-specific ligands, while transactivation by RXR-nur77 is induced by RXR-specific ligands (15, 49). These observations

* Corresponding author. Mailing address: The Burnham Institute, La Jolla Cancer Research Center, 10901 N. Torrey Pines Road, La Jolla, CA 92037. Phone: (619) 646-3141. Fax: (619) 646-3195. E-mail: xzhang@ljcrf.edu.

suggest that RAR β can be induced by both RAR- and RXR-specific ligands. nur77 is an orphan member of nuclear receptor superfamily that regulates gene expression by binding to the nur77-binding response element (NBRE) as a monomer (64). It is rapidly induced by various stimuli, including growth factors and phorbol ester- and cyclic AMP-dependent synthesis pathways (20, 39). Recent studies suggest that nur77 is involved in activation-induced apoptosis of T cells (35, 65) and is associated with *trans*-RA resistance in human lung cancer cells (66). Thus, RAR β expression is regulated by growth signals and may be associated with the apoptotic process.

Recently, evidence has emerged that the absence or aberrant expression of RAR β correlates with malignancy and may contribute to the development of cancers. The involvement of RAR β in cancer development was originally implicated in the finding that the RAR β gene is integrated by hepatitis B virus in human liver cancer (9). Subsequent reports indicate that abnormal expression of the RAR β gene appears to be involved in the tumorigenicity of human papillomavirus type 18-transformed ovarian cancer cells (1) and the neoplastic progression of human oral squamous cell carcinoma cell lines (24), and it is observed in many other human cancer cell lines (16, 22, 24, 34, 48, 58, 69). RAR β also suppresses the growth of breast cancer cells (33, 34, 58) and lung cancer cells (23). The auto-induction of RAR β gene expression presumably plays a critical role in amplifying retinoid responses and is associated with the growth-inhibitory effects of *trans*-RA in breast cancer cells in vitro (34) and the clinical response to retinoids in patients with premalignant oral lesions (37). Retinoids that fail to induce RAR β expression cannot arrest the growth of melanoma cells (5).

The involvement of retinoid receptors in mediating retinoid-induced growth inhibition and apoptosis has been investigated. Several studies demonstrated that expression of RAR α mediates the growth-inhibitory effect of *trans*-RA in estrogen-dependent breast cancer cells and that the loss of *trans*-RA sensitivity in estrogen-independent cells may be due to low levels of RAR α (34, 51, 55, 60). RAR α levels are higher in certain estrogen-dependent, *trans*-RA-sensitive breast cancer cell lines, such as ZR-75-1, MCF-7, and T-47D, than in certain estrogen-independent, *trans*-RA-resistant cells lines, such as MDA-MB-231 and MDA-MB-468 (34, 51, 55, 60). Expression of RAR α in estrogen-independent, *trans*-RA-resistant MDA-MB-231 breast cancer cells restored *trans*-RA sensitivity (34, 54, 55, 61). Growth inhibition induced by retinoids in estrogen-dependent MCF-7 breast cancer cells correlated with their binding affinity to RAR α (7). The involvement of RAR β was suggested by the observation that it was expressed in response to *trans*-RA in certain estrogen-dependent, *trans*-RA-sensitive breast cancer cell lines, such as ZR-75-1 and T-47D, but not in estrogen-independent, *trans*-RA-resistant cell lines MDA-MB-231, MDA-MB-468, and BT-20 (34). In addition, we (34) and others (33, 53) demonstrated that introduction of RAR β into MDA-MB-231 cells led to the recovery of *trans*-RA-induced growth inhibition. Moreover, RAR β expression was enhanced in RAR α stably transfected MDA-MB-231 cells, a finding that suggests that RAR β may mediate the growth inhibitory effects of RAR α (34). The role of RAR β in growth inhibition is also supported by the observation that as normal human mammary epithelial cells senesce, RAR β mRNA expression increases (58). RAR γ is highly expressed in various breast cancer cell lines independently of their estrogen responsiveness (34) and is unlikely involved in regulating *trans*-RA-induced growth inhibition and apoptosis. However, recent studies (11, 12) have demonstrated that it may play a role in mediating growth inhibition and apoptosis induction by 4-HPR and certain syn-

thetic retinoids. 4-HPR was a potent transactivator of RAR γ at concentrations that inhibited the growth and induced apoptosis of breast cancer cells (11). Furthermore, growth inhibition by certain receptor-selective retinoids and interferons was associated with increased expression of RAR γ (12). Thus, different retinoid receptors, which may function through different mechanisms, can mediate growth inhibition and apoptosis induction by different types of retinoids in breast cancer cells.

In this study, we evaluated the effects of RAR- and RXR-class selective retinoids on the growth of *trans*-RA-resistant, RAR α -deficient MDA-MB-231 cells. Our results demonstrate that RXR-selective retinoids induced RAR β expression, growth inhibition, and apoptosis in these cells, most likely through their activation of RXR-nur77 heterodimers that bind to the RAR β promoter. When we stably expressed RAR α in MDA-MB-231 cells, we observed an enhanced growth inhibition and RAR β induction by RAR-selective retinoids and decreased effects by RXR-selective retinoids, similar to those observed in *trans*-RA-sensitive, RAR α -expressing breast cancer cells, such as ZR-75-1 cells. Thus, an RXR-mediated growth inhibition pathway exists in breast cancer cells and is regulated by RAR α levels. These results may provide a novel method for inhibiting the growth of the more malignant *trans*-RA-resistant breast cancer cells.

MATERIALS AND METHODS

Retinoids. *trans*-RA was obtained from Sigma (St. Louis, Mo.). SR11246, SR11237, and SR11235 were prepared as described by Dawson et al. (8). Synthesis of SR11383 was described elsewhere (16a).

(*E*)-3-[4-(1-Methoxy-5,6,7,8-tetrahydro-1-5,5,8,8-tetramethyl-3-naphthalenyl)phenyl]propenoic acid (SR11278) was synthesized as follows. (i) Cyclalkylation [AlCl₃, (CH₂Cl)₂, 0°C] of 3-bromoanisole with 2,5-dichloro-2,5-dimethylhexane as reported by Kagechika et al. (26) yielded 3-bromo-1-methoxy-5,6,7,8-tetrahydro-5,5,8,8-tetramethylnaphthalene (71%), which was coupled under Suzuki conditions {Pd[P(C₆H₅)₃]₄, NaHCO₃, aqueous 1,2-dimethoxyethane [MeO(CH₂)₂OMe], reflux} (41) with 4-formylphenylboronic acid to give 4-(1-methoxy-5,6,7,8-tetrahydro-5,5,8,8-tetramethyl-3-naphthalenyl)benzaldehyde (91%). (ii) Horner-Emmons olefination of this benzaldehyde with triethyl phosphonoacetate [KN(SiMe₃)₂, tetrahydrofuran-toluene, -78 to 25°C] produced the ethyl ester of SR11278 (97%). (iii) Hydrolysis (KOH, aqueous ethanol [EtOH]; aqueous HCl) gave SR11278 (99%); melting point (mp), 179 to 182°C; ¹H nuclear magnetic resonance (NMR) (300 MHz, ²HClCl₃) δ 1.34 (s, 6, CMe₂), 1.41 (s, 6, CMe₂), 1.68 (m, 4, CH₂CH₂), 3.89 (s, 3, OMe), 6.49 (d, *J* = 16.0 Hz, 1, C=CHCO₂), 6.90 (d, *J* = 1.8 Hz, 1, ArH), 7.20 (d, *J* = 1.8 Hz, 1, ArH), 7.62 (s, 4, ArH), 7.83 (d, *J* = 16.0 Hz, 1, HC=CCO₂); infrared (IR) (KBr) 2,955, 1,700, 1,630, 1,430, 1,278, 1,220, 825 cm⁻¹.

4-[3-Hydroxy-5,6,7,8-tetrahydro-3,5,5,8,8-tetramethyl-2-naphthalenyl]carboxamide (SR11281) was synthesized as follows. (i) Fries rearrangement (AlCl₃, 130°C [23]) of 2-acetoxy-5,6,7,8-tetrahydro-5,5,8,8-tetramethylnaphthalene produced 1-(3-hydroxy-5,6,7,8-tetrahydro-5,5,8,8-tetramethylnaphthalen-2-yl)ethanone (90%). (ii) Protection of the phenolic group as the benzyl ether (benzyl bromide, K₂CO₃, acetone, reflux; 92%) and oxidation of the acetyl group (NaOCl, EtOH, reflux) gave 3-benzyloxy-5,6,7,8-tetrahydro-5,5,8,8-tetramethylnaphthalene-2-carboxylic acid (30%). (iii) The carboxylic acid was converted (oxalyl chloride, CH₂Cl₂) to the acyl chloride and treated (pyridine-benzene) with ethyl 4-aminobenzoate to yield the benzamide (95%). (iv) Ester hydrolysis (NaOH, aqueous EtOH, 25°C; aqueous HCl; 97%) and hydrogenolysis [H₂, Pd(C), EtOH, 25°C; 93%] of the benzyl ether protecting group afforded SR11281: mp, 275 to 278°C; ¹H NMR (300 MHz, ²HClCl₃) δ 1.29 (s, 6, CMe₂), 1.32 (s, 6, CMe₂), 1.69 (s, 4, CH₂CH₂), 6.93 (s, 1, ArH), 7.69 (s, 1, ArH), 7.74 (d, 2, *J* = 8.8 Hz, ArH), 8.08 (d, 2, *J* = 8.8 Hz, ArH); IR (KBr) 3,330, 1,686, 1,530, 1,419, 1,174 cm⁻¹.

4-[1-(5,6,7,8-Tetrahydro-3,5,5,8,8-pentamethyl-2-naphthalenyl)-2-methylpropenyl]benzoic acid (SR11345) was prepared by Suzuki Pd(0)-catalyzed coupling {Pd[P(C₆H₅)₃]₄, NaHCO₃, aqueous MeO(CH₂)₂OMe, reflux; 58%} (8) between 5,6,7,8-tetrahydro-3,5,5,8,8-pentamethylnaphthalene-2-boronic acid and methyl (1-bromo-2-methylpropenyl)benzoate and hydrolysis (KOH, aqueous EtOH; aqueous HCl; 91%). The first intermediate was synthesized in two steps by bromination (Br₂, CHCl₃, 25°C; 80%) of 5,6,7,8-tetrahydro-3,5,5,8,8-pentamethylnaphthalene, followed by conversion to the arylboronic acid [*n*-butyllithium (*n*-BuLi), tetrahydrofuran (THF), -78°C to ambient temperature; B(OMe)₃, -78°C to ambient temperature; aqueous NH₄Cl; 86%]. The second intermediate was obtained from methyl (2-methylpropenyl)benzoate by bromination (Br₂, CH₂Cl₂; 100%) and debromination {1,8-diazabicyclo[5.4.0]undec-7-ene, MeO(CH₂)₂OMe, 25°C; 90%} to yield SR11345: mp, 246 to 247°C; ¹H NMR

($^2\text{HCCl}_3$) δ 1.25 (s, 12, 4CH₃), 1.64 (s, 3, CH₃), 1.66 (s, 3, CH₃), 1.88 [s, 4, (CH₂)₂], 1.99 (s, 3, CH₃), 7.00 (s, 1, ArH), 7.03 (s, 1, ArH), 7.25 (d, J = 8.3, 2, ArH), 7.98 (d, J = 8.3, 2, ArH); IR (KBr) 3,500 to 2,300 (OH), 1,687 (C = O), 1,606 (C = C) cm^{-1} ; chemical ionization high-resolution mass spectrum (CI-HRMS) (NH₃) calculated for C₂₆H₂₂O₂ + NH₄⁺, 394.2746; found, 394.2751.

4-(1-Amino-5,6,7,8-tetrahydro-5,5,8,8-tetramethylanthracen-2-yl)benzoic acid (SR11350) was synthesized by nitration (HNO₃, acetic anhydride-acetic acid [Ac₂O-HOAc], -10°C) of 6-bromo-1,2,3,4-tetrahydro-1,1,4,4-tetramethylanthracene to give after chromatographic separation (silica, CH₂Cl₂-hexanes) of isomers 6-bromo-1,2,3,4-tetrahydro-1,1,4,4-tetramethyl-5-nitroanthracene (26%), which was coupled {Pd[P(C₆H₅)₃]₄, NaHCO₃, aqueous dimethyl ether (DME), 80°C; 83%} to 4-carboxyphenylboronic acid to afford ethyl 4-(1-nitro-5,6,7,8-tetrahydro-5,5,8,8-tetramethylanthracen-2-yl)benzoate. Hydrogenation [H₂, Pd(C), EtOAc, 25°C; 95%] to the amine and ester hydrolysis (KOH, aqueous EtOH; 85°C; aqueous HCl; 93%) yielded SR11350 as the HCl: salt mp, 267 to 268°C; ¹H NMR (300 MHz, Me₂SO- d_6) δ 1.40 (s, 6, CH₃), 1.44 (s, 6, CH₃), 1.77 (s, 4, CH₂), 7.25 (d, J = 8.6 Hz, 1, ArH) 7.55 (d, J = 8.6 Hz, 1, ArH), 7.55 (d, J = 8.2 Hz, 2, ArH), 7.90 (s, 1, ArH), 8.11 (d, J = 8.2 Hz, 2, ArH), 8.21 (s, 1, ArH); electron impact high-resolution mass spectrum (EI-HRMS) calculated for C₂₅H₂₇NO₂, 373.2042; found, 373.2040.

6-[3-(1-Adamantyl)-5-methoxyphenyl]naphthalene-2-carboxylic acid (SR11362) was obtained by hydrolysis (KOH, aqueous EtOH, 85°C; aqueous HCl; 90%) of its ethyl ester: mp, 236 to 238°C; ¹H NMR (300 MHz, $^2\text{HCCl}_3$) δ 1.79 (m, 6, CH₂), 1.98 (m, 6, CH₂), 2.12 (m, 3, CH), 3.87 (s, 3, OCH₃), 6.96 (s, 1, ArH), 7.02 (s, 1, ArH), 7.28 (s, 1, ArH), 7.75 (m, 1, ArH), 7.96 (m, 3, ArH), 8.12 (d, J = Hz, 1, ArH), 8.68 (s, 1, ArH); EI-HRMS calculated for C₂₈H₂₈O₃, 412.2038; found, 412.2030.

2-(4-Carboxyphenyl)-6,7,8,9-tetrahydro-6,6,9,9-tetramethylbenzo[g]quinoline-1-oxide (SR11365) was prepared by acetylation (Ac₂O, Et₃N, EtOAc, 25°C; 100%) of 5,6,7,8-tetrahydro-5,5,8,8-tetramethylnaphthalene-2-amine to the amide, which on reaction with excess Vilsmeier reagent {[POC]₃, 8.5 equivalents; alerts dimethylformamide (DMF) 3.5 equivalents; alerts (CH₂Cl)₂, 0°C; 25 to 85°C; aqueous NaHCO₃; 61%} produced 2-chloro-6,7,8,9-tetrahydro-6,6,9,9-tetramethylbenzo[g]quinoline-3-carboxaldehyde, which on coupling {Pd[P(C₆H₅)₃]₄, NaHCO₃, aqueous DME, 80°C; 71%} with 4-carboxyphenylboronic acid yielded ethyl 4-[3-formyl-6,7,8,9-tetrahydro-6,6,9,9-tetramethylbenzo[g]quinolin-2-yl]benzoate. Oxidation of the formyl group to the carboxylic acid with concomitant base hydrolysis of the ester (Ag₂O, NaOH, aqueous EtOH-THF, 25°C; H₂O⁺; 100%) gave the dicarboxylic acid, which on thermal decarboxylation (315°C; 93%) yielded 4-[6,7,8,9-tetrahydro-6,6,9,9-tetramethylbenzo(g)quinolin-2-yl]benzoic acid, which has also been synthesized by another route (26). Esterification (SOCl₂, reflux; MeOH-C₆H₅N-C₆H₅CH₃; aqueous NaHCO₃; 91%), N-oxidation (3-ClC₆H₄CO₂H, CHCl₃, 25°C; 85%), and ester hydrolysis (NaOH, aqueous EtOH, 70°C; aqueous citric acid; 72%) yielded SR11365: mp, >300°C; ¹H NMR (300 MHz, Me₂SO- d_6) δ 1.42 (s, 12, CH₃), 1.80 (s, 4, CH₂), 7.68 (d, J = 9 Hz, 1, ArH), 7.95 (d, J = 9 Hz, 1, ArH), 8.10 (d, J = 8 Hz, 2, ArH), 8.14 (s, 1, ArH), 8.15 (d, J = 8 Hz, 2H, ArH), 8.63 (s, 1, ArH); EI-HRMS calculated for C₂₄H₂₅NO₃, 375.1834; found, 375.1832.

Cell culture. Breast cancer cell lines ZR-75-1, T-47D, and MDA-MB-231 were obtained from the American Type Culture Collection. ZR-75-1 and T-47D cells were grown in RPMI 1640 medium supplemented with 10% fetal calf serum, and MDA-MB-231 and CV-1 cells were grown in Dulbecco modified Eagle medium supplemented with 10% fetal calf serum.

Growth inhibition assay. To study anchorage-dependent growth inhibition, cells were seeded at 500 cells per well in 96-well plates and treated with solvent control (dimethyl sulfoxide-EtOH) or with 10⁻⁶ M retinoids (or 10⁻⁷ M *trans*-RA) in solvent. Media were changed every 48 h. After treatment for 10 days, the number of viable cells were determined by their capacity to convert the tetrazolium salt 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium (MTT) into a blue formazan product, using a cell proliferation-cytotoxicity assay kit (Promega, Madison, Wis.) (46).

RNA preparation and Northern blot. For Northern blot analysis, total RNAs were prepared by the guanidine hydrochloride-ultracentrifugation method (34). About 30- μg aliquots of total RNAs from different cell lines treated with or without 10⁻⁶ M retinoids (or 10⁻⁷ M *trans*-RA) were fractionated on 1% agarose gel, transferred to nylon filters, and probed with the ³²P-labeled ligand-binding domain of receptor cDNAs as previously described (34). To determine that equal amounts of RNA were used, the filters were also probed with β -actin.

Plasmids, receptor proteins, and nuclear extract preparation. The nur77 expression vector was constructed by cloning the nur77 cDNA fragment into pECE or pBluescript vector as described previously (66). The construction of the chloramphenicol acetyltransferase (CAT) reporter containing the RAR β promoter (*Bg*II-*Bam*HI fragment) and expression vectors for RAR α , RAR β , and RXR α have been described elsewhere (21, 67, 68). The RXR α N-terminal deletion mutant (Δ RXR10) was constructed by deleting 61 amino acid residues from its N-terminal end as described previously (71). Receptor proteins were synthesized by an in vitro transcription-translation system using rabbit reticulocyte lysate (Promega) as described previously (67). The relative amount of the translated proteins was determined by [³⁵S]methionine-labeled protein on sodium dodecyl sulfate-polyacrylamide gels by quantitating and then normalizing the amount of incorporated radioactivity relative to the content of methionine in each protein. Nuclear extracts were prepared as previously described (34).

TABLE 1. Retinoid transcriptional activation activity

Retinoid	Relative receptor transactivation (%) ^a			
	RAR α	RAR β	RAR γ	RXR α
<i>trans</i> -RA	100	100	100	53
9- <i>cis</i> -RA				100
SR11277	5	149	65	0
SR11278	13	145	67	0
SR11281	59	123	133	0
SR11365	95	56	48	6
SR11383	66	71	16	7
SR11235	3	27	0	51
SR11246	6	12	9	98
SR11237	1	44	0	95
SR11345	0	-6	-12	107

^a Transcriptional activation in CV-1 cells, using the (TREpal)₂-*tk*-CAT reporter, compared to 1 μM *trans*-RA for RARs or 1 μM 9-*cis*-RA for RXR α as 100%.

Gel retardation assay. The gel retardation assay using in vitro-synthesized proteins or nuclear extracts has been described previously (67, 68). When antibodies were used, 1 μl of anti-nur77 (Santa Cruz Biotechnology, Inc., Santa Cruz, Calif.) or 1 μl of anti-RXR (32) was incubated with receptor protein at room temperature for 30 min prior to the assay.

Transient transfection and CAT assay. To measure transcriptional activation of the RAR β promoter by retinoids, this promoter (*Bg*II-*Bam*HI fragment) was linked to the CAT gene reporter (21). The reporter plasmid and β -galactosidase expression vector (pCH110; Pharmacia) (100 ng each) with or without the RAR β expression vector were transiently transfected into CV-1 cells by the calcium phosphate precipitation method (34). Cells were grown in the presence or absence of 10⁻⁶ M retinoids or 10⁻⁷ M *trans*-RA. Transfection efficiency was normalized to β -galactosidase activity. The data shown are the means of three separate experiments.

Stable transfection. RAR α cDNA was cloned into the pRc/CMV expression vector (Invitrogen, San Diego, Calif.) as described elsewhere (34). The resulting recombinant constructs were then stably transfected into MDA-MB-231 breast cancer cells by the calcium phosphate precipitation method and screened by using G418 (Gibco BRL, Grand Island, N.Y.). The levels of exogenous RAR α expression were determined by Northern blotting.

Apoptosis analysis. Cells were treated with or without 10⁻⁶ M retinoids (or 10⁻⁷ M *trans*-RA). After 48 h, cells were trypsinized, washed with phosphate-buffered saline (PBS; pH 7.4), and fixed in 1% formaldehyde in PBS. After washing with PBS, cells were resuspended in 70% ice-cold EtOH and immediately stored at -20°C overnight. Cells were then labeled with biotin-16-dUTP by terminal deoxynucleotidyltransferase (TdT) and stained with avidin-fluorescein isothiocyanate (Boehringer, Mannheim, Germany). Fluorescently labeled cells were analyzed using a FACScater-Plus as described previously (34). Representative histograms are shown.

RESULTS

RXR-selective retinoids inhibit the growth and induce the apoptosis of *trans*-RA-resistant MDA-MB-231 but not *trans*-RA-sensitive ZR-75-1 cells. Because *trans*-RA effectively inhibited the growth and induced the apoptosis of *trans*-RA-sensitive, estrogen-dependent ZR-75-1 breast cancer cells, whereas it had little effect on *trans*-RA-resistant, estrogen-independent MDA-MB-231 breast cancer cells (34), RAR- and RXR-class selective retinoids (Table 1) were evaluated for the ability to inhibit the growth and induce the apoptosis of these cell lines. At 10⁻⁶ M, SR11278, SR11281, SR11277, SR11383, and SR11365 activated only the RARs, not RXR α , on the (TREpal)₂-*tk*-CAT reporter construct (67, 68), as determined by transient transfection in CV-1 cells. SR11237, SR11246, and SR11235 activated both RXR α and RAR β , whereas SR11345 activated only RXR α (Table 1). Both breast cancer cell lines were treated for 10 days with 10⁻⁶ M the indicated class-selective retinoid alone or the combination of RXR-selective SR11345 and a RAR-selective retinoid. Cell viability was determined by the MTT assay. As shown in Fig. 1, the RAR-selective retinoids strongly inhibited ZR-75-1 cell growth (55

FIG. 1. Growth-inhibitory effects of retinoids on *trans*-RA-sensitive, estrogen-dependent ZR-75-1 and *trans*-RA-resistant, estrogen-independent MDA-MB-231 breast cancer cells. Cells (800 cells/well) were seeded in 96-well plates and treated with the indicated retinoids (10^{-6} M) or *trans*-RA (10^{-7} M) alone or in combination for 10 days. The number of viable cells was determined by the MTT assay.

to 75%). In contrast, the RXR-selective retinoids were far less effective inhibitors (8 to 25%) of growth. ZR-75-1 cell growth inhibition by any of the RAR-selective retinoids was only slightly enhanced by the RXR-selective SR11345. Therefore, growth inhibition of *trans*-RA-sensitive ZR-75-1 cells by retinoids is mediated mainly by the RAR pathway, not the RXR pathway, a finding which is consistent with previous observations (34, 55). Interestingly, in MDA-MB-231 cells, RXR-selective SR11237, SR11246, or SR11235 at 10^{-6} M inhibited growth (45 to 50%) more effectively than any RAR-selective retinoid, which was a poor inhibitor (<20%) (Fig. 1). The more RXR-specific retinoid SR11345 was less effective, with only 8% inhibition. However, when it was used together with one of the RAR-selective retinoids, growth inhibition was increased to 40 to 55%. These results indicate that activation of both RAR and RXR signaling pathways is required for effective cancer cell growth inhibition.

We next investigated the apoptosis-inducing effects of RAR-selective SR11365 and *trans*-RA and of RXR-selective SR11246 in ZR-75-1 and MDA-MB-231 cells by the TdT assay (Fig. 2). *trans*-RA at 10^{-7} M and SR11365 at 10^{-6} M significantly induced apoptosis of ZR-75-1 cells, producing 58 and 27% apoptosis, respectively, whereas RXR-selective SR11246 produced only about 5% apoptotic cells (Fig. 2A). About 44% of MDA-MB-231 cells underwent apoptosis on treatment with SR11246, but apoptosis was not significant on treatment with *trans*-RA (4%) or SR11365 (6%) (Fig. 2B). Together, these results demonstrated that RXR-selective retinoids can induce growth inhibition and apoptosis of *trans*-RA-resistant MDA-MB-231 cells, whereas RAR-selective retinoids are more effective in *trans*-RA-sensitive cells.

Induction of RAR β in *trans*-RA-resistant breast cancer cells by RXR-selective retinoids. We previously demonstrated that RAR β expression levels in breast cancer cells correlated with the extent of growth inhibition and apoptosis induction by *trans*-RA (34). To determine whether growth inhibition and apoptosis induction by RXR-selective retinoids in *trans*-RA-resistant MDA-MB-231 cells were also associated with their

induction of RAR β , we compared the effect of RXR-selective retinoids SR11246 and SR11345 and RAR-selective SR11365, as well as the SR11345 and SR11365 combination, on RAR β expression in these cells (Fig. 3). For comparison, *trans*-RA-sensitive ZR-75-1 and T-47D cells were studied. Both *trans*-RA and RAR-selective SR11365, but not RXR-selective SR11246 or SR11345, induced RAR β expression in ZR-75-1 and T-47D cells. However, RXR-selective SR11246 and SR11345 induced RAR β expression in *trans*-RA-resistant MDA-MB-231 cells at a level comparable to that observed with *trans*-RA or SR11365. A further induction of RAR β was observed when MDA-MB-231 cells were treated with both RXR-selective SR11345 and RAR-selective SR11365. These results demonstrate that activation of RXR by RXR-selective retinoids induced RAR β in *trans*-RA-resistant MDA-MB-231 cells, while these retinoids were unable to activate the RXR-pathway for inducing RAR β in *trans*-RA-sensitive ZR-75-1 and T-47D breast cancer cells. Thus, induction of RAR β by RXR-selective retinoids may contribute to the effects of these retinoids on growth inhibition and apoptosis induction in *trans*-RA-resistant MDA-MB-231 cells.

RXR-selective retinoids activate the RAR β promoter through RXR-nur77 heterodimers. RXR ligands can regulate gene expression through RXR homodimers (68) or certain RXR heterodimers, such as RXR-RAR (4, 31), RXR-LXR (63), or RXR-nur77 (15, 49). Regulation of gene expression by RXR-nur77 heterodimers occurs through their binding to DR-5 type RAREs (15, 49). Because the β RARE in the RAR β promoter is a DR-5 type RARE and contains an NBRE (15, 49, 64), we investigated whether induction of RAR β expression in MDA-MB-231 cells (Fig. 3) could be due to apparent activation of RXR-nur77 heterodimers on the β RARE by RXR-selective retinoids. nur77 alone did not show any clear binding to the β RARE under our experimental conditions but in the presence of RXR produced a strong complex, whose binding was largely affected by either anti-RXR or anti-nur77 antibody (Fig. 4A). For a better distinction between RXR-RAR and RXR-nur77 heterodimers, an RXR α mutant with a deletion of

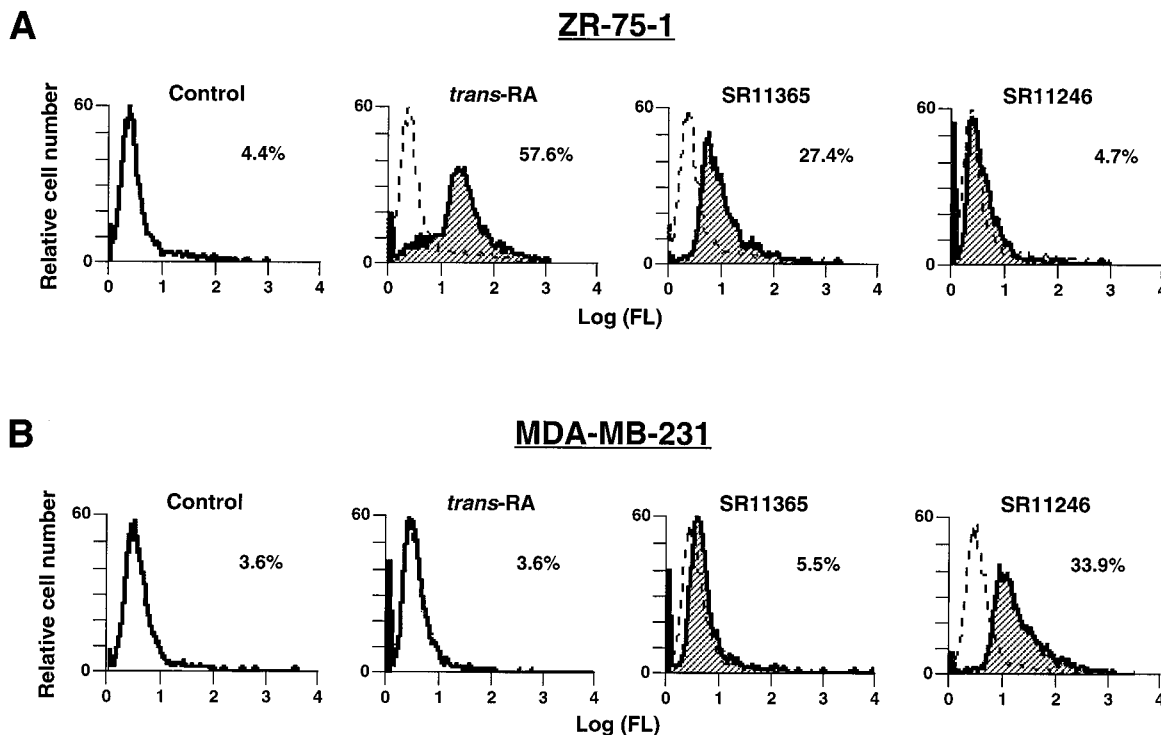

FIG. 2. Induction of apoptosis by retinoids in *trans*-RA-sensitive, estrogen-dependent ZR-75-1 (A) and *trans*-RA-resistant, estrogen-independent MDA-MB-231 (B) breast cancer cells. Breast cancer cells were grown in the presence of the indicated retinoids at 10^{-6} M or *trans*-RA at 10^{-7} M for 48 h. DNA fragmentation was determined by the TdT assay. Representative histograms show relative apoptotic cell number. FL, fluorescence.

68 amino acid residues from its N-terminal end (71) was used. The deletion did not affect heterodimerization properties of the RXR with RAR or nur77 (data not shown). The binding of the RXR-nur77 heterodimers to the β RARE was comparable to that of the RXR-RAR heterodimers (Fig. 4A). Thus, the unique structure of the β RARE permits binding of both RXR-RAR and RXR-nur77 heterodimers, as previously observed (15, 49). We next carried out transient transfection assays in CV-1 cells, using the RAR β promoter linked to the CAT gene (21) as a reporter. As shown in Fig. 4B, cotransfection of the RXR α expression vector did not induce reporter transcrip-

tional activity in response to RXR-selective SR11246 or SR11345, a result that suggests that RXR homodimers do not activate the RAR β promoter as previously observed (68). Cotransfection of the nur77 expression vector clearly induced reporter activity in response to these RXR-selective retinoids but not to RAR-selective *trans*-RA or SR11365. When nur77 and RXR expression vectors were cotransfected, a stronger induction of reporter activity was observed when cells were treated with the RXR-selective retinoids but not with *trans*-RA or SR11365. To determine the effect of RAR α on RXR-nur77 activity, we cotransfected the RAR α expression vector together with RXR α and nur77. Addition of RAR α strongly inhibited RXR-selective retinoid-induced reporter activity but significantly enhanced *trans*-RA and SR11365 activity (Fig. 4B). The inhibition of SR11246 and SR11345 activity by RAR α is likely due to competition of RAR α and nur77 for heterodimerization with RXR and binding to the β RARE, which suggests that RXR-selective retinoids SR11246 and SR11345 cannot activate RAR β promoter through RXR-RAR heterodimers in CV-1 cells.

Competitive binding of RXR-RAR and RXR-nur77 heterodimers to the β RARE. Our observation that RAR α inhibited the transactivation activities of RXR-selective SR11246 and SR11345 on the β RARE (Fig. 4B) suggests that RAR α may compete with nur77 for heterodimerization with RXR and thus prevent nur77 from binding to the β RARE. We therefore carried out gel retardation assay using the β RARE as a probe (Fig. 5). When RAR α protein was added, binding of RXR α -nur77 heterodimers to the β RARE decreased in a RAR α dose-dependent manner. Excess amounts of RAR α permitted binding of RXR α -RAR α heterodimers. Similarly, increasing nur77 protein levels inhibited RXR-RAR heterodimer binding

FIG. 3. Effects of RAR-selective SR11365 and RXR-selective SR11246 and SR11345 on RAR β gene expression in *trans*-RA-sensitive, estrogen-dependent ZR-75-1 and T-47D and *trans*-RA-resistant, estrogen-independent MDA-MB-231 cells. RNAs were prepared from cells treated with 10^{-6} M RXR-selective SR11246 or SR11345, RAR-selective SR11365, or a combination of SR11345 and SR11365 for 24 h and analyzed for RAR β expression by Northern blotting. For comparison, the expression of the β -actin is shown.

FIG. 4. Binding and transactivation of nur77-RXR α and RAR α -RXR α on the β RARE. (A) Binding of the nur77-RXR α and RAR α -RXR α heterodimers to the β RARE. Equal amounts of in vitro-synthesized nur77 and an N-terminally deleted RXR α (see Materials and Methods) alone or combined with the β RARE probe at room temperature for 10 min. Mixtures were incubated with the β RARE probe at room temperature for 10 min. Mixtures were analyzed by gel retardation. Anti-RXR (α RXR), anti-RAR α (α RAR α), or anti-nur77 (α nur77) was incubated with receptor proteins for 30 min at room temperature before performance of the assay. For a control, receptor proteins were also incubated with preimmune serum (PI). The β RARE probe sequence was GTAGGGTTCACCGAAAGTTCAGTC (the NBRE is in boldface). (B) nur77-promoted transactivation of RAR β in CV-1 cells. A CAT reporter containing the RAR β promoter (19) was transiently transfected into CV-1 cells with the receptor expression vector RXR α (20 ng), nur77 (100 ng), or RAR α (200 ng). After 24 h, cells were treated with the indicated retinoids (10^{-6} M) or *trans*-RA (10^{-7} M) for 24 h, and CAT activities were determined as described elsewhere (65).

to the β RARE but enhanced RXR-nur77 heterodimer binding. Thus, RAR α and nur77 compete for dimerization with RXR and binding to the β RARE. These data suggest that the relative levels of RAR α and nur77 regulate binding of RXR-nur77 and RXR-RAR to the β RARE. We therefore determined whether different levels of RAR α , RXR α , and nur77 were expressed in *trans*-RA-sensitive ZR-75-1 and in *trans*-RA-resistant MDA-MB-231 cells. Consistent with previous observations (34, 51, 54, 55, 60), RAR α levels were much higher in ZR-75-1 cells than in MDA-MB-231 cells (Fig. 6). However, RXR α and nur77 were equally expressed in both cell lines

FIG. 5. Competition binding of RXR-RAR and RXR-nur77 heterodimers to the β RARE. To analyze the effect of RAR α on RXR-nur77 heterodimer binding to the β RARE, in vitro-synthesized N-terminally deleted RXR α protein (1 μ l) was incubated with in vitro-synthesized nur77 (2 μ l) in the absence or presence of the indicated amounts (microliters) of in vitro-synthesized RAR α protein and analyzed by gel retardation using the β RARE probe. To analyze the effect of nur77 on RXR α /RAR α heterodimer binding, in vitro-synthesized RXR α protein (1 μ l) was incubated with in vitro-synthesized RAR α (2 μ l) in the absence or presence of the indicated amounts (μ l) of in vitro-synthesized nur77 and analyzed by gel retardation.

independently of the presence of *trans*-RA. The high RAR α levels in ZR-75-1 cells suggest that binding of RXR α -RAR α heterodimers to the β RARE may preferentially occur to mediate the effects of RAR-selective ligands, while the low RAR α levels in MDA-MB-231 cells suggest that RXR-nur77 heterodimer may be predominantly formed with the β RARE to mediate the inhibitory effects of RXR-selective ligands.

Stable expression of RAR α in *trans*-RA-resistant MDA-MB-231 cells favors the RAR pathway over the RXR pathway. Low levels of RAR α in MDA-MB-231 cells should enhance RXR-nur77 heterodimer formation to mediate the effects of RXR-selective retinoids. To determine whether overexpression of RAR α would allow RXR-RAR heterodimer formation but inhibit that of RXR-nur77, we stably transfected RAR α into

FIG. 6. Expression of RAR α , RXR α , and nur77 in *trans*-RA-sensitive ZR-75-1 and *trans*-RA-resistant MDA-MB-231 cells. Total RNAs, prepared from cells treated with 10^{-7} M *trans*-RA for 24 h, were analyzed for the expression of RAR α , RXR α , and nur77 by Northern blotting. For comparison, the expression of the β -actin is shown.

FIG. 7. Effect of stable expression of RAR α on growth inhibition and RAR β induction by RXR-selective and RAR-selective retinoids in *trans*-RA-resistant MDA-MB-231 cells. (A) RAR α modulates sensitivity of MDA-MB-231 cells to RAR-selective and RXR-selective retinoids. Stable clones, expressing introduced RAR α , were seeded at 800 cells/well in 96-well plates and treated with the indicated retinoid (10^{-6} M) or *trans*-RA (10^{-7} M) for 10 days. The number of viable cells was determined by the MTT assay. (B) Stable expression of RAR α regulates RAR β expression in response to RAR-selective and RXR-selective retinoids in MDA-MB-231 cells. Stable MDA-MB-231 clones expressing high levels of RAR α (MB-231/RAR α 2 and MB-231/RAR α 4) were treated with the indicated retinoid (10^{-6} M) alone or in combination and analyzed for the expression of RAR β by Northern blotting. The expression of β -actin was used as the control.

this cell line. Two stable clones (MDA-MB-231-RAR α 2 and MDA-MB-231-RAR α 4) that expressed high levels of transfected RAR α (data not shown) were analyzed for their responses to RAR and RXR class-selective retinoids (Fig. 7A). Compared to their effects in the parental MDA-MB-231 cells (Fig. 1), RAR-selective *trans*-RA at 10^{-7} M and SR11365 at 10^{-6} M were far more potent inhibitors of the stable clones, showing 46 to 62% inhibition, while RXR-selective SR11246, SR11237, and SR11345 were less effective inhibitors, with less than 21% inhibition. We also investigated the effect of RAR α on RAR β expression in MDA-MB-231 cells by Northern blotting (Fig. 7B). In contrast to their effects on the parental cells (Fig. 3), RAR-selective *trans*-RA and SR11365 strongly induced RAR β expression in both clones, while RXR-selective retinoids SR11246 and SR11345 did not. These results demonstrate that low RAR α expression in MDA-MB-231 cells is responsible for the increased ability of RXR-selective retinoids and the decreased ability of RAR-selective retinoids to induce RAR β expression and growth inhibition. The fact that the extent of growth inhibition and RAR β expression level by these receptor class-selective retinoids in the stable clones were similar to those in *trans*-RA-sensitive ZR-75-1 and T-47D cells (Fig. 1 and 3) suggests that the differential effects of

retinoids on certain *trans*-RA-sensitive and -resistant breast cancer cell lines depend on different levels of RAR α expression.

Binding of nuclear proteins from ZR-75-1 and MDA-MB-231 cells to the β RARE. To provide direct evidence that relative levels of RXR, RAR α , and nur77 in *trans*-RA-sensitive ZR-75-1 and *trans*-RA-resistant MDA-MB-231 cells allowed different complex formation on the β RARE, we prepared nuclear proteins from ZR-75-1 and MDA-MB-231 cells and analyzed their binding to the β RARE (Fig. 8). Nuclear proteins

FIG. 8. β RARE binding activities of nuclear proteins from ZR-75-1, MDA-MB-231, and MDA-MB-231-RAR α 4 cells. (A) Nuclear proteins from ZR-75-1 (2 μ g), MDA-MB-231 (5 μ g), and MDA-MB-231-RAR α 4 (2 μ g) cells were analyzed by gel retardation assay using β RARE as a probe. When antibody (designated as in Fig. 4A) was used, it (1 μ l) was incubated with nuclear proteins for 30 min at room temperature before performance of the assay. Preimmune serum (PI) was used for control. (B) Comparison of β RARE and $\Delta\beta$ RARE binding of nuclear proteins from ZR-75-1 (2 μ g), MDA-MB-231 (2 μ g), and MDA-MB-231/RAR α 4 (2 μ g) cells by gel retardation assay. The $\Delta\beta$ RARE probe sequence was GTAGGGTTCACCGTGAGTTCAGTC (mutated nucleotides compared to β RARE are indicated in boldface).

from ZR-75-1 cells formed several strong complexes with the β RARE. When they were incubated with anti-RXR antibody, the slowly migrating complexes were inhibited. When anti-RAR α antibody was used, some of the slowly migrating complexes were also abolished. However, anti-nur77 antibody did not show any detectable effect on the binding. These data demonstrate that RXR and RAR α are mainly responsible for β RARE binding in ZR-75-1 cells. When nuclear proteins from MDA-MB-231 cells were analyzed, we observed weak β RARE binding complexes, which could be inhibited by anti-RXR and anti-nur77 antibodies but not by anti-RAR α antibody. Thus, expression of RXR and nur77 in MDA-MB-231 cells (Fig. 6) could contribute to the β RARE binding activities. To determine whether overexpression of RAR α in MDA-MB-231 cells could prevent RXR-nur77 binding as we observed by using in vitro-synthesized receptor proteins (Fig. 5), we analyzed the binding of nuclear proteins prepared from MDA-MB-231-RAR α 4 cells. As shown in Fig. 8A, the nuclear proteins formed a strong complex with the β RARE, which could be completely inhibited by either anti-RXR antibody or anti-RAR α antibody but not by anti-nur77 antibody, indicating that overexpression of RAR α in MDA-MB-231 cells inhibited RXR-nur77 heterodimer binding and permitted RXR-RAR heterodimer binding. To further determine the nature of the binding complexes from different cell lines, we used a mutated β RARE ($\Delta\beta$ RARE), in which two adenine nucleotides in the spacing region of the β RARE were mutated. The mutations do not affect binding of RXR-RAR heterodimers but abolish RXR-nur77 binding (66) and thereby allow distinction of RXR-RAR heterodimers from RXR-nur77 heterodimers. When nuclear proteins from ZR-75-1, MDA-MB-231, and MDA-MB-231-RAR α 4 were analyzed on the $\Delta\beta$ RARE, we observed a strong binding of nuclear proteins from ZR-75-1 and MDA-MB-231-RAR α 4 cells, similar to that observed with the β RARE. In contrast, nuclear proteins from MDA-MB-231 cells did not show any detectable binding on the $\Delta\beta$ RARE, demonstrating that the binding complex that we observed on the β RARE might represent RXR-nur77 heterodimer binding.

DISCUSSION

Breast cancer cell growth inhibition and apoptosis induction by RXR-selective retinoids. Although conventional retinoids show promise in animal models as preventive agents against breast cancer, their anticancer effects appear to be limited to *trans*-RA-sensitive tumors, whereas the more aggressive, estrogen-independent tumors are usually refractory (14, 34, 54, 55, 60). In this study, we demonstrated that several RXR-selective retinoids inhibit the growth and induce the apoptosis of *trans*-RA-resistant MDA-MB-231 cells (Fig. 1), provided that they are also capable of activating the RARs or are used in combination with RAR-selective retinoids. Efficient growth inhibition by RXR-selective retinoids appears to be cell type specific because it was observed in *trans*-RA-resistant MDA-MB-231 cells but not in *trans*-RA-sensitive ZR-75-1 cells (Fig. 1). In ZR-75-1 cells, RAR-selective SR11365 was much more effective than RXR-selective SR11246 in inhibiting the growth and inducing apoptosis (Fig. 1 and 2). Thus, different retinoid signaling pathways preferentially operate in *trans*-RA-sensitive and *trans*-RA-resistant breast cancer cells to mediate retinoid-induced growth inhibition.

Although the RXR pathway is clearly involved in *trans*-RA-resistant MDA-MB-231 breast cancer cell growth inhibition, a clear growth inhibition by RXR-selective retinoids required a longer period of treatment (Fig. 1) than that by RAR-selective

retinoids, which usually inhibit the growth of *trans*-RA-sensitive breast cancer cells over a period of 3 to 4 days of treatment (data not shown). This observation suggests that the effects of RXR-selective retinoids may involve a mechanism different from that utilized by RAR-selective retinoids. We showed that activation of RXR alone was insufficient for growth inhibition and that activation of RAR appeared to be required, as indicated by our observation that RXR-selective SR11237, SR11246, and SR11247, which at 1 μ M have the ability to slightly activate the RAR β (Table 1), can significantly inhibit the growth of MDA-MB-231 cells (Fig. 1), whereas the far more RXR-selective SR11345, which activates RXR α comparably to the other RXR-selective retinoids (Table 1), did not significantly inhibit MDA-MB-231 cell growth (Fig. 1). Furthermore, RXR-selective SR11345 and RAR-selective SR11365, which alone were ineffective inhibitors, on combination strongly prevented MDA-MB-231 cell growth (Fig. 1). The biological activities of RXR-selective retinoids have been described in several studies (6, 17, 47). Activation of RXR was reported as essential for inducing apoptosis in HL-60 leukemia cells (47). RXR-selective retinoid LGD1069 effectively inhibited the tumor development in the *N*-nitroso-*N*-methylurea-induced rat mammary tumor model (17). Because of their increased efficacy against malignant, *trans*-RA-resistant, estrogen-independent breast cancer growth, RXR-selective retinoids may be useful for chemoprevention and chemotherapy of breast cancer.

How RXR-selective retinoids inhibit the growth and induce the apoptosis of *trans*-RA-resistant MDA-MB-231 and other cancer cells remains to be fully elucidated. Induction of growth inhibition and apoptosis of breast cancer cells by retinoids may involve different retinoid receptors and different mechanisms, depending on types of retinoids and cell lines (11, 12, 33, 34, 53–55, 60). The effects of *trans*-RA may be mediated by RAR α and RAR β (33, 34, 53–55, 60), whereas activation of RAR γ may be required for other retinoids, such as 4-HPR (11, 12). Our data presented here suggest that induction of RAR β may be involved. This is consistent with previous observations that RAR β could mediate the growth-inhibitory effect of *trans*-RA in breast cancer cells (33, 34, 53). RAR β was induced by *trans*-RA only in *trans*-RA-sensitive ZR-75-1 and T-47D, not in *trans*-RA-resistant MDA-MB-231, breast cancer cells (34). In addition, introduction of RAR β into RAR β -negative MDA-MB-231 breast cancer cell lines restored *trans*-RA-induced growth inhibition (33, 34, 53), while inhibition of RAR β activity in the RAR β -positive ZR-75-1 cells with an antisense construct abolished growth inhibition by *trans*-RA (34). Furthermore, enhancement of RAR β levels has been found to correlate with senescence in normal mammary epithelial cells (58). In *trans*-RA-sensitive ZR-75-1 and T-47D cells, RAR β expression was strongly induced by RAR-selective *trans*-RA and SR11365, which also inhibited growth and induced apoptosis, whereas RAR β expression was not induced by RXR-selective SR11246 and SR11345, which only poorly inhibited growth and only weakly induced apoptosis (Fig. 3). The fact that RXR-selective retinoids could induce RAR β expression in *trans*-RA-resistant MDA-MB-231 cells (Fig. 3) suggests that induction of RAR β may contribute to their effects on MDA-MB-231 cells. However, because *trans*-RA and SR11365 induced RAR β to levels similar to those induced by RXR-selective retinoids SR11246 and SR11345 in MDA-MB-231 cells (Fig. 3) but were poor growth inhibitors (Fig. 1), mechanisms other than RAR β induction may also be involved.

SR11345 synergized with RAR-selective retinoids to inhibit MDA-MB-231 cell growth (Fig. 1). Such synergism of RAR- and RXR-selective retinoids has recently been observed in the

activation of several RA-responsive genes, including RAR β , during embryonal carcinoma cell differentiation (52) and in NB4 acute promyelocytic leukemia cells (4). The synergism that we observed here may in part arise from induction and activation of RAR β . Growth inhibition of MDA-MB-231 cells may require both induction and activation of RAR β because RXR-specific SR11345 is a much less effective inhibitor than other RXR-selective retinoids (Fig. 1), which also slightly activate RAR β (Table 1). Enhanced induction of RAR β in MDA-MB-231 cells by the combination of RXR-specific SR11345 and RAR-selective SR11365 (Fig. 3) may also contribute to their synergistic growth inhibition.

Regulation of RAR β expression. The β RARE in the RAR β promoter is responsible for regulating RAR β expression by retinoids (10, 21, 57). Our observation in gel shift assays that efficient binding to the β RARE occurred by heterodimerization of RXR α with nur77 or RAR α but not by either receptor alone (Fig. 4A) confirms that the β RARE binds both RXR-RAR and RXR-nur77 heterodimers (15, 49). Activation of the β RARE by *trans*-RA is caused by binding and activation of RAR-RXR heterodimers, in which RXR functions as a silent partner (15, 30, 38), while activation of the β RARE by RXR-selective retinoids occurs on binding of RXR-nur77 heterodimers (15, 49). Cotransfection of RXR α and nur77 strongly activated RAR β promoter activity in response to RXR-selective SR11246 or SR11345 but not to RAR-selective *trans*-RA or SR11365 (Fig. 4B). Thus, the β RARE can be activated by either a RAR-selective or RXR-selective retinoid signaling pathway through binding of RXR-RAR or RXR-nur77, respectively. This is reminiscent of a previous observation that the β RARE bound strongly to an RXR-containing complex other than RXR-RAR in S91 melanoma cell extracts (56). Because nur77 expression is induced by several growth factors having different signal transduction pathways (20, 39), the binding and activation of the β RARE by nur77 and retinoid receptors will mediate the convergence of retinoid and growth factor signaling pathways.

Activation of the β RARE by the RAR pathway or RXR pathway depends on the breast cancer cell type. In *trans*-RA-sensitive cell lines such as ZR-75-1 and T-47D, the expression of RAR β was highly induced by RAR-selective retinoids but not by RXR-selective retinoids, whereas in *trans*-RA-resistant MDA-MB-231 cells, RAR β expression was induced by RXR-selective retinoids (Fig. 3). Because both RXR α and nur77 are well expressed in MDA-MB-231 cells (Fig. 6), induction of RAR β by RXR-selective retinoids is likely mediated by activation of RXR-nur77 heterodimers on the β RARE. This is further supported by our observation that binding of nuclear proteins prepared from MDA-MB-231 cells to the β RARE may represent RXR-nur77 heterodimers (Fig. 8). Such cell-type-specific activation of the β RARE has been observed previously. In CV-1 cells, RXR-selective retinoids did not appreciably transactivate the DR-5 β RARE even in the presence of transfected RAR and RXR (15, 30). However, in P19 or F9 embryonal carcinoma cells, RXR ligands contributed to transcriptional activation of genes containing DR-5 elements (4, 40, 52). The cell-type-specific activation of the β RARE is likely due to the relative levels of nuclear receptors that bind the β RARE and modulate its activity.

Although RXR-selective retinoids could induce RAR β expression in MDA-MB-231 cells, we observed a stronger induction of RAR β when cells were treated with a combination of RAR-selective and RXR-selective retinoids (Fig. 3). The strong induction of RAR β by the combination may be due to the additive effect of RXR-RAR and RXR-nur77 heterodimers, since RAR-selective retinoids by themselves could

also slightly induce RAR β probably due to low levels of RAR α expressed in these cells. Recently, it was reported that binding of RAR-selective retinoids to RXR-RAR heterodimers allowed binding and activation of RXR-RAR heterodimers by RXR-selective retinoids (4, 40). Thus, it is also possible that the strong induction of RAR β that we observed by the combination of RAR-selective and RXR-selective retinoids is due to activation of RXR-RAR heterodimers prebound with RAR-selective retinoid.

RAR α regulates both RAR and RXR pathways. *trans*-RA-sensitive and -resistant breast cancer cell lines display different responses to retinoid receptor class-selective ligands. RAR-selective retinoids are potent RAR β inducers and growth inhibitors in *trans*-RA-sensitive ZR-75-1 cells, while RXR-selective retinoids effectively induce RAR β and inhibit the growth of *trans*-RA-resistant MDA-MB-231 cells (Fig. 1 and 3). The observation that the β RARE can be activated by either RXR-RAR or RXR-nur77 suggests that the pathway that mediates growth inhibition and RAR β induction may largely depend on the relative levels of RAR α , RXR α , and nur77. In lung cancer cell lines, nur77 expression is associated with *trans*-RA resistance (66) and could be critical in regulating RAR and RXR activities. However, in breast cancer cell lines, ZR-75-1 and MDA-MB-231 cell lines express similar levels of RXR α and nur77, while RAR α varies, being highly expressed in the former and underexpressed in the latter (Fig. 6), as has been previously observed (34, 51, 55, 60). Thus, RAR α levels appear to be most important for determining whether the RAR or RXR pathway will regulate growth inhibition by retinoids. High RAR α levels in *trans*-RA-sensitive ZR-75-1 cells may permit formation of RXR-RAR heterodimers that bind to the β RARE (Fig. 5 and 8) to mediate the effects of RAR-selective retinoids in inducing RAR β expression and growth inhibition (34) but prevent RXR α from forming RXR-nur77 heterodimers (Fig. 5 and 8) so that RXR-selective retinoids are unable to inhibit growth or induce apoptosis despite the abundant expression of nur77. In contrast, low RAR α levels in *trans*-RA-insensitive MDA-MB-231 cells (Fig. 6) allow formation of RXR-nur77 heterodimers (Fig. 8) that bind to the β RARE to mediate RAR β expression and may be responsible for growth inhibition in the presence of RXR-selective retinoids. The importance of RAR α levels in determining the regulatory pathway is supported by our gel retardation (Fig. 5 and 8) and transfection assay results (Fig. 4B). Gel retardation indicates that binding of RXR-RAR or RXR-nur77 heterodimers to the β RARE largely depends on RAR α protein levels (Fig. 5 and 8). Overexpression of RAR α in MDA-MB-231 cells allowed binding of RXR-RAR α heterodimers and prevented binding of RXR-nur77 heterodimers to the β RARE (Fig. 5 and 8). In transient transfection assays, cotransfection of RAR α inhibited RXR-selective retinoid-induced RXR-nur77 heterodimer activity on the RAR β promoter (Fig. 4B). Furthermore, stable expression of RAR α in MDA-MB-231 cells strongly enhanced growth inhibition (Fig. 7A) and RAR β induction (Fig. 7B) by RAR-selective retinoids and decreased the inhibitory effects of RXR-selective retinoids. Thus, high RAR α levels favor formation of RAR-RXR heterodimers and the RAR signaling pathway in breast cancer cells, while low RAR α levels favor the formation of nur77-RXR heterodimers and the RXR signaling pathway. This retinoid signaling switch may play an important role in regulating breast cancer cell growth in response to different growth factor and retinoid stimuli.

In summary, we have demonstrated that RXR-selective retinoids inhibit the growth and induce the apoptosis of *trans*-RA-resistant MDA-MB-231 breast cancer cells, which appears to

be mediated through RXR-nur77 heterodimers that bind and activate the β RARE in the presence of RXR-selective retinoids, resulting in induction of RAR β , which may then be activated by RAR-selective retinoids to initiate secondary biological responses. RXR-nur77 heterodimer formation in *trans*-RA-resistant MDA-MB-231 cells is favored by very low RAR α levels, whereas high expression of RAR α in *trans*-RA-sensitive ZR-75-1 cells favors formation of RXR-RAR heterodimers that bind and activate the β RARE in response to RAR-selective ligands. Thus, the convergence and switch of RAR-dependent and RXR-dependent signaling on the β RARE is very likely regulated by relative RAR α levels. Our findings that an RXR signaling pathway can mediate growth inhibition and apoptosis induction and the additive to synergistic effects of a RAR-selective and RXR-selective retinoid combination on *trans*-RA-resistant MDA-MB-231 cell growth may provide a therapeutic opportunity to inhibit the growth of more invasive, *trans*-RA-resistant breast cancer by using lower retinoid doses to reduce toxicity.

ACKNOWLEDGMENTS

We thank S. E. Harris for the human nur77 expression vector, S. Waldrop for preparation of the manuscript, and Guo-quan Chen for technical assistance.

This work was supported in part by National Institutes of Health grants CA60988 (X.-K.Z.) and CA51933 (M.I.D. and X.-K.Z.) and U.S. Army Medical Research Program grant DAMD17-4440 (X.-K.Z.). A.A. was supported by a fellowship from the Breast Cancer Research Program, University of California.
