Abstract: An antifungal protein was isolated from a culture of *Bacillus subtilis* strain B29. The isolation procedure comprised ion exchange chromatography on diethylaminoethyl (DEAE)-52 cellulose and gel filtration chromatography on Bio-Gel® P-100. The protein was absorbed on DEAE-cellulose and Bio-Gel® P-100. The purified antifungal fraction was designated as B29I, with a molecular mass of 42.3 kDa by sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE), pI value 5.69 by isoelectric focusing (IEF)-PAGE, and 97.81% purity by high performance liquid chromatography (HPLC). B29I exhibited inhibitory activity on mycelial growth in *Fusarium oxysporum*, *Rhizoctonia solani*, *Fusarium moniliforme*, and *Sclerotinia sclerotiorum*. The 50% inhibitory concentrations (IC_{50}) of its antifungal activity toward *Fusarium oxysporum* and *Rhizoctonia solani* were 45 and 112 $\mu\text{mol/L}$, respectively. B29I also demonstrated an inhibitory effect on conidial spore germination of *Fusarium oxysporum* and suppression of germ-tube elongation, and induced distortion, tumescence, and rupture of a portion of the germinated spores.

Key words: *Bacillus subtilis*, Antifungal protein, Purification

CLC number: Q81

INTRODUCTION

Antifungal proteins and peptides have been isolated from a great number of animals (Iijima *et al.*, 1993; Wang and Ng, 2002), plants (Benhamou *et al.*, 1993; Joshi *et al.*, 1998; Lam *et al.*, 2000), bacteria (Delcambe *et al.*, 1977; Kim and Chung, 2004; Moyne *et al.*, 2004), and fungi (Lam and Ng, 2001b; Wang and Ng, 2004; Theis *et al.*, 2005). Based on their structures or functions, antifungal proteins and peptides can be classified into many different classes, such as thaumatin-like proteins (Pressey, 1997; Wurms *et al.*, 1999; Ye *et al.*, 1999), glucanases (Vogelsang and Barz, 1993), chitinases and chiti-

nase-like proteins (Benhamou *et al.*, 1993; Lam *et al.*, 2000; Lam and Ng, 2001c), peroxidases (Ye and Ng, 2002b), ribonucleases (Ng and Wang, 2001; Liu *et al.*, 2007), protease inhibitors (Joshi *et al.*, 1998), ribosome inactivating proteins (Leah *et al.*, 1991; Lam and Ng, 2001a), lectins (Broekaert *et al.*, 1989; Ye *et al.*, 2001), cyclophilin-like proteins (Ye and Ng, 2000; 2002a), lipid transfer protein-like proteins (Molina *et al.*, 1993; Wang *et al.*, 2004), and miraculin-like proteins (Ye *et al.*, 2000).

Recently, *Bacillus subtilis* strains have been applied to control plant diseases (Hwang and Chakravarty, 1992; Asaka and Shoda, 1996; Wulff *et al.*, 2002; Okigbo, 2005), as they are ubiquitous in soils, have high thermal tolerance, grow quickly in liquid culture, and readily form resistant spores. Additionally, *B. subtilis* non-ribosomally synthesizes several kinds of small antibiotic peptides (<2000 Da) that have antifungal activities, such as iturin (Delcambe *et*

al., 1977; Tsuge *et al.*, 2001; Stein, 2005), surfactin (Peypoux *et al.*, 1999; Carrillo *et al.*, 2003), fengymycin, bacilysin (Loeffler *et al.*, 1986), bacillomycin (Peypoux *et al.*, 1980), mycosubtilin (Peypoux *et al.*, 1986), and mycobacillin (Majumdar and Bose, 1960; Sengupta *et al.*, 1971). *B. subtilis* also secretes an abundance of proteins (Moyné *et al.*, 2004; Liu *et al.*, 2007). However, little is known about the antifungal activity of these proteins. In our previous study, we have isolated an antagonistic strain *B. subtilis* B29, which strongly inhibits pathogens such as *Fusarium*, *Pythium*, and *Rhizoctonia* on potato dextrose agar (PDA) plates, and controls vegetable and melon wilt diseases in field (Li and Yang, 2005). We have also found that B29 secretes antifungal proteins and obtained the optimum fermentation conditions to secrete antifungal proteins (Li *et al.*, 2008). This study reports the isolation, purification, and preliminary characterization of a novel antifungal protein secreted by *B. subtilis* B29.

MATERIALS AND METHODS

Chemicals

All chemicals were of analytical grade. Bovine serum albumin (BSA) was obtained from Sigma (USA), diethylaminoethyl (DEAE)-52 cellulose from Whatman (USA), and Bio-Gel® P-100 from Bio-Rad (USA). Low-molecular weight protein standards were purchased from TaKaRa Biotechnology (Dalin) Co., Ltd. (China).

Organism and growth conditions

The strain of *Bacillus subtilis* B29 was isolated in the Institute of Microbiology of Heilongjiang Academy of Sciences (IMHAS) from a sample of soil collected at the suburb of Harbin City (China), and identified as *Bacillus subtilis* on the basis of its morphological, biochemical and physiological characteristics, and 16S rDNA analysis (Li and Yang, 2005). The strain was deposited in the own microbiology strain collection in the IMHAS. B29 was cultured in 250-ml Erlenmeyer flasks containing 50 ml of NYD medium (10 g glucose, 8 g beef extract, and 5 g yeast extract) in a rotary shaker at 150 r/min at 30 °C for 5 d. Its pH was adjusted to 7.5 before autoclaving at 121 °C for 15 min. On completion of

the culture, the bacteria were removed by centrifugation at 6000 r/min for 30 min at 4 °C, and the supernatant was used for crude proteins isolation.

Fusarium oxysporum f. *cucumerinum* was isolated from wilted cucumber roots and stored at 4 °C in PDA. It was incubated on Petri plates containing 15 ml PDA under sterile conditions at room temperature [(28±2) °C] for 5 d to prepare a conidial suspension for later use.

Isolation and purification of antifungal protein

The precipitate from cell-free culture broth supernatants by ammonium sulphate at 30% (w/v) saturation was collected by centrifugation at 6000 r/min for 30 min and discarded. The crude proteins were precipitated from the supernatant at 70% (w/v) (NH₄)₂SO₄ saturation. The latter was added in small portions with constant stirring for 30 min. The stirring was continued for 1 h, and the mixture was kept overnight at 4 °C. The precipitate was collected by centrifugation at 6000 r/min for 30 min, dissolved in a 1/15 (v/v) phosphate buffer (0.02 mol/L, pH 6.8), and dialyzed for 24 h with 4 changes in the same buffer (500 ml each) to remove ammonium sulphate. The dialysates were condensed to yield crude proteins, which were further purified by column chromatography. A part of the crude proteins were dissolved in 5 ml of phosphate buffer (0.02 mol/L, pH 6.8), and the antifungal activity of the crude proteins was tested against *Fusarium oxysporum*.

Chromatography was carried out on a DEAE-52 cellulose ion exchange column (2.5 cm×50 cm; Whatman) previously equilibrated with 0.02 mol/L phosphate buffer (pH 6.8). The column was first eluted with 500 ml of the same buffer (pH 6.8) to yield unadsorbed proteins, and subsequently with a linear gradient of 0~1 mol/L NaCl in phosphate buffer (0.02 mol/L, pH 6.8) to desorb the adsorbed proteins (fractions I, II, III, IV). Each fraction was dialyzed in distilled water to remove NaCl, and then adjusted to the same concentration with phosphate buffer. Antifungal activity was tested against *Fusarium oxysporum*. Fraction I was subsequently chromatographed on Bio-Gel® P-100 column (1.6 cm×50 cm; Bio-Rad). The column was eluted with 0.02 mol/L phosphate buffer (pH 6.8) to collect one main protein peak (P₁) and another small protein peak (P₂). The antifungal activity of the two fractions was tested. All

purification processes were carried out with a Nucleic acid-Protein Detective System (8823A-UV MONITOR, Beijing, China). P₁ representing the purified antifungal protein was designated as B29I.

Electrophoresis, molecular mass, pI value and protein concentration determination

The molecular mass of the purified antifungal protein from *B. subtilis* strain B29 was conducted by sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE), according to the procedure of Laemmli and Favre (1973) using a 12% (w/v) gel and 5% (w/v) stacking gel. The gel was stained with Coomassie brilliant blue after electrophoresis. The molecular mass of B29I was determined by comparison of its electrophoretic mobility with those of molecular mass marker proteins (TaKaRa Biotechnology (Dalin) Co., Ltd., China). The pI value of the purified antifungal protein was determined by isoelectric focusing (IEF)-PAGE. The protein concentration was determined using the method of Bradford (1976), with bovine serum albumin as a standard.

High performance liquid chromatography (HPLC) and mass spectrum analysis

The purity of the purified antifungal protein from *B. subtilis* strain B29 was analyzed by the C18 reversed phase column HPLC system. The HPLC was conducted on an Agilent zorbax 300SB-C18 column (4.6 mm×150 mm; 3.5 μm; 30 nm): the mobile phases A 0.1% (v/v) trifluoroacetic acid (TFA)-water solution and B 0.1% (v/v) TFA-acetonitrile solution, with gradient elution. The detection wavelength was 280 nm and column temperature 25 °C.

The antifungal protein B29I separated by SDS-PAGE was analyzed after in-gel digestion by National Center of Biomedical Analysis (NCBA), Beijing, China. The peptide-mass fingerprinting (PMF) was obtained by matrix assisted laser desorption/ionization-time of flight (MALDI-TOF) mass spectrometry and searched in Mascot.

N-terminal sequence analysis

The N-terminal amino acid sequence of the antifungal protein B29I was determined by means of automated Edman degradation using an ABI Pro-cise™ 492cLC protein sequencer equipped with an HPLC system.

Assay of antifungal activity

The assay of the purified protein B29I for antifungal activity toward *Fusarium oxysporum* f. *cucumerinum* and *Rhizoctonia solani* was carried out on 100 mm×15 mm Petri plates each containing 10 ml of PDA. After the mycelial colony had developed, sterile blank paper disks (0.65 cm in diameter) were placed at a distance of 0.5 cm away from the rim of the mycelial colony. An aliquot (10 μl) containing either 9 or 36 μg of the purified protein B29I was added to each disk. The plates were sealed with parafilm, and incubated at 28 °C until mycelial growth had enveloped disks containing the control and had formed crescents of inhibition around disks containing samples with antifungal activity (Lam et al., 2000).

To determine the 50% inhibitory concentrations (IC₅₀) for the antifungal activity, three doses of the antifungal protein B29I were added separately to three aliquots each containing 4 ml PDA at 45 °C, mixed rapidly, and poured into three separate small Petri dishes. After the agar had cooled down, a small amount of mycelia, the same amount to each plate, was added. Buffer without B29I served only as control, and all the plates were cultured at 28 °C. When the mycelia colony of the control had grown to almost fill the plate, the area of the mycelia colony was measured, and the inhibition of fungal growth in the other plates was determined by calculating the percent reduction in the area of the mycelia colony (Wang and Ng, 2004).

Bioassay of the antifungal protein B29I on *Fusarium oxysporum* conidial spore germination

The inhibitory effect of the purified antifungal protein B29I on conidial spore germination of *Fusarium oxysporum* f. *cucumerinum* was examined. 80 μl of 0.2% (w/v) sterile glucose, 80 μl of purified antifungal protein B29I (0.9 μg/μl) and 40 μl of *Fusarium oxysporum* conidial suspension (1×10^4 spore/ml) were mixed completely in an Eppendorf tube. Sterile phosphate buffer (0.02 mol/L, pH 6.8) was used as a control. 100 μl of the mixture was added into a hollow-ground slide with a cover, and then incubated in the dark at room temperature [(28±2) °C] in humidified Petri dishes with three replicates. The sample was observed under a microscope at regular intervals, and the percentage spore germination was determined.

RESULTS

Isolation and purification of antifungal protein

Ion exchange chromatography of *B. subtilis* strain B29 culture extract on a DEAE-52 column contained one unadsorbed fraction and four adsorbed fractions (I, II, III, and IV) (Fig.1). Of these fractions, only fraction I showed strong antifungal activity (Fig.2), and fraction II showed a less antifungal activity. Fraction I was resolved on the Bio-Gel® P-100 column into two fractions (P_1 and P_2) (Fig.3). Only fraction P_1 exhibited antifungal activity (Fig.2) and showed a single band with a molecular mass of 42.3 kDa in SDS-PAGE (Fig.4). This single-band antifungal protein was designated as B29I. Its purity was 97.81% as detected by HPLC and its pI value was 5.69 as determined by IEF-PAGE. The protein yields at various stages of chromatographic purification are shown in Table 1.

Sample: fraction I from DEAE-52 column chromatography. Buffer: 20 mmol/L $\text{Na}_2\text{HPO}_4/\text{NaH}_2\text{PO}_4$ (pH 6.8). Flow rate: 0.4 ml/min

Amino acid sequence analysis

The PMF of antifungal protein B29I was obtained by MALDI-TOF mass spectrometry, and was an unreported protein as searched in the Mascot database. Subsequently, the digestion products of B29I were detected by ESI-QUADRUPOLE-OA-TOF (Q-TOF2), and three random double electric charge segments were chosen to be detected by collision-induced dissociation (CID). The amino acid sequences of three peptide segments were KTHVLEDEFK, KGQQTG DFGAYLH, and RTYEVAEESPVLGL respectively.

Lane 1: purified antifungal protein B29I; Lane M: low molecular mass markers from TaKaRa Biotechnology (China)

The N-terminal amino acid sequence of the antifungal protein B29I was different from those of other antifungal proteins from *Bacillus subtilis* (Table 2). However, a random amino acid sequence (RTY EVAAEESPVLGL) from B29I showed slight resemblance to a small portion of those antifungal proteins from *Bacillus subtilis* (Table 2).

Antifungal activity of B29I

Antifungal activity of B29I toward *Fusarium oxysporum*, *Rhizoctonia solani*, *Fusarium moniliforme*, and *Sclerotinia sclerotiorum* was observed (Fig.5). Of the various fungal species, *Fusarium oxysporum* and *Rhizoctonia solani* showed the highest sensitivity to the antifungal protein B29I. The IC₅₀ values of the inhibitory activity of the antifungal protein B29I on hyphal growth in *Fusarium oxysporum* and *Rhizoctonia solani* were 45 and 112 μmol/L, respectively. Antifungal activity was discernible at various temperatures up to 80 °C, but disappeared at 100 °C (Fig.6).

The purified antifungal protein B29I was strongly inhibitory to conidial spore germination of *F. oxysporum*, and suppressive to germ-tube elongation (Table 3). Percentage spore germination of the control increased with time from 18% at 8 h to 97.5% at 16 h. At that time, mycelia were growing after germ-tube emergence, growth and elongation. However, no spore germination was observed after treatment with antifungal protein B29I (72 μg). When incubation time was increased to 24 h, 22.7% spore germination and germ-tube emergence were detected after treatment with B29I. In addition, a portion of germinated spores of *F. oxysporum* appeared distorted, tumescent, and ruptured (Fig.7), and the germ-tube was unable to

elongate anymore, while percentage spore germination was 100%, and mycelial extension also occurred in the control. At 36 h and 72 h, 60% of spores incubated with antifungal protein B29I germinated, but less mycelial growth was observed compared with the control. The purified antifungal protein B29I showed an inhibitory effect on conidial spore germination of *F. oxysporum*, germ-tube elongation, and mycelial development.

DISCUSSION

This paper reports a novel antifungal protein, designated as B29I, isolated from *Bacillus subtilis* strain B29. The molecular mass of the antifungal protein B29I was different from those of other reported antifungal proteins from *B. subtilis*, such as bacisubin (41.9 kDa) (Liu et al., 2007), YxjF (fragment) (12.23 kDa), endo-1-4- β -glucanase (46.60 kDa), YnfF (45.39 kDa), BamD (44.94 kDa), putative sensor kinase (53.38 kDa), bacillomycin D synthetase C (309.04 kDa) (NCBI search), and X98III (59.0 kDa) (Xie et al., 1998). The N-terminal amino acid

sequence of the antifungal protein B29I was distinctly different from those of the abovementioned antifungal proteins. However, a random amino acid sequence (RTYEVAEESPVLGL) from B29I was slightly similar to a small portion of the sequences in BamD, bacillomycin D synthetase C, endo-1-4- β -glucanase, YxjF (fragment), putative sensor kinase, and YnfF (Table 2), and those antifungal proteins from *Bacillus subtilis* demonstrated antifungal activity toward *Aspergillus flavus* (Moyne et al., 2004).

The antifungal spectra of those reported antifungal proteins from *B. subtilis* were different. Bacisubin secreted from *B. subtilis* strain B-916 strongly inhibited mycelial growth in some species of *Alternaria* and *Botrytis*, while the antifungal protein B29I inhibited mycelial growth in *Fusarium oxysporum*, *Rhizoctonia solani*, *Fusarium moniliforme*, and *Sclerotinia sclerotiorum*. The IC₅₀ values of antifungal activity of B29I toward *F. oxysporum* and *R. solani* were as low as 45 and 112 μ mol/L, respectively. The antifungal protein B29I was also strongly inhibitory to conidial spore germination of *F. oxysporum*, suppressive to germ-tube elongation, and induced distortion, tumescence, and rupture of a portion of

germinated spores of *F. oxysporum*. The fairly high thermostability of antifungal protein B29I was noteworthy.

The antifungal protein B29I was absorbed on DEAE-cellulose, unlike most of the antifungal proteins and peptides reported earlier (Wang and Ng, 2002; 2004; Ngai *et al.*, 2005). Its chromatographic behaviors on DEAE-cellulose and Bio-Gel® P-100 were distinct from those of other antifungal proteins (Lam *et al.*, 2000; Ng and Wang, 2001; Liu *et al.*, 2007).

Bacillus subtilis can produce more than two dozens of antibiotics with an amazing variety of structures. Most of the anti-microbial active compounds produced include peptides that are either ribosomally synthesized and post-translationally modified (lantibiotics and lantibiotic-like peptides), or are non-ribosomally generated. Some non-peptidic compounds such as polyketides, an aminosugar, and a phospholipid are also produced (Stein, 2005). The lipoheptapeptide (surfactin) is the most powerful biosurfactant known; it exerts a detergent-like action on biological membranes (Carrillo *et al.*, 2003), and is distinguished by its exceptional emulsifying, foaming, anti-viral and anti-mycoplasma activities. The iturines and the bacillomycins possess strong anti-fungal and haemolytic properties, but exhibit only limited anti-bacterial activity. The properties, activities, and genes for biosynthesis of lipopeptide antibiotics have been intensively investigated (Stein, 2005; Tsuge *et al.*, 2001). The differences of antifungal protein B29I in biochemical and biological characteristics from known antifungal molecules produced by *Bacillus subtilis* indicate that the antifungal protein B29I is a novel antifungal protein. Additionally, the report of antifungal protein B29I constitutes an addition to the scanty literature on *Bacillus subtilis* antifungal proteins.

ACKNOWLEDGMENT

The authors thank Dr. Sheau-fang Hwang (Crop Diversification Centre North, Canada), Dr. Ying Ma (Food Science and Engineering, Harbin Institute of Technology, China), and Dr. Shu-xia Bai (Chapel Hill School of Medicine, University of North Carolina, USA) for their critical review of the manuscript, National Center of Biomedical Analysis (Beijing, China)

for mass spectrum analysis and Shanghai GeneCore BioTechnologies Co. Ltd. (Shanghai, China) for N-terminal amino acid sequence analysis of the purified protein.
