Box 9517, 2300 RA Leiden, The Netherlands

Abstract

The dramatic biogeographical variations in the secondary metabolites from *Psammocinia* aff. *bulbosa* have complicated our efforts to re-isolate the two most cytotoxic of its metabolites, (+)-psymberin and (+)-cyclocinamide A. Reported now are the results of a new study that demonstrates our ability to repeatedly isolate these two compounds through targeted collection efforts. Additional study of the new sample of (+)-cyclocinamide A has enabled finalizing its biological activity and absolute stereochemistry as 4*S*, 7*S*, 11*S*, 14*S*.

In the early 1990s we began a campaign to survey the chemical ecology of *Psammocinia* aff. *bulbosa* communities from Papua New Guinea. It is now clear that a side-by-side chemical and taxonomic examination is obligatory to differentiate among populations of *Psammocinia* (Dictyoceratida, Irciniidae), *Cacospongia* (Dictyoceratida, Thorectidae), or *Ircinia* (Dictyoceratida, Irciniidae)¹ having very similar morphologies. Recognizing this critical step made it possible to engage in a meaningful synopsis of the chemical variations observed for a small library of *P.* aff. *bulbosa* specimens. Reported now are the final results of a project whose goals were to: (a) obtain fresh sponge specimens containing both psymberin and cyclocinamide A in order to facilitate on-going molecular genetics studies on their biosynthetic pathways,² (b) complete the full absolute chirality assignment for cyclocinamide A,^{3,4} and (c) accumulate additional biological activity data for cyclocinamide A.³

Outlined in Table 1 are an astonishing variety of biosynthetic products that we have observed to date from six distinct collections whose voucher material has each been identified as *Psammocinia* aff. *bulbosa*. The major constituents of specimens I–V range from sesterterpenes (variabilin⁵), polyketides (preswinholide A⁶ and swinholide A^{6,7}), a cyano-sponge cyclic hexapeptide (psymbamide A⁷), a halogenated hexapeptide (cyclocinamide A³), to a NRPS-PKS mixed biogenetic derived compound (psymberin⁸). By contrast, meroterpenes (cacospongin B⁹ and chromarol D⁹) usually observed from sponges of *Cacospongia*-genus were isolated from sample VI. Though samples V and VI were obtained from adjacent sites, the chemical profiles of their major constituents clearly showed the biosynthetic machinery of these two sponge collections was distinct. These plus the other dramatic biogeographical

variations shown in Table 1 complicated our efforts to re-isolate the two most structurally unique of these metabolites, psymberin and cyclocinamide A.

Before proceeding, it is important to briefly review the historical record highlighted in Figure 1 pertaining to absolute stereochemical assignments for psymberin and cyclocinamide A. The 5*S*, 8*S*, 9*S*, 11*R*, 13*R*, 15*S*, 16*R*, 17*R* structure we originally proposed for (+)-psymberin⁸ (**1a**) was reaffirmed from two independent total syntheses of **1c**.^{10,11} The synthetic products also provided the basis for the 4*S* designation at the single unassigned carbon and verified that (+)-psymberin (**1a**) we isolated from *P. aff. bulbosa* was identical to (+)-ircinistatin A¹² (**1b**) reported by Pettit from *Ircinia cf. ramosa*. Four additional diastereomers were also created during these synthesis projects and the most important included **1d** and **1e**.^{10,11,13} The stereostructure of (+)-cyclocinamide A (**2a**), we described in 1997, included firm assignments at 7*S* and 14*S* but the 4*S* and 11*S* designations were speculative.³ In 1998, a total synthesis by Grieco afforded the 4*R*, 7*S*, 11*R*, 14*S* structure **2b** (no $[\alpha]$ reported), whose ¹H NMR spectra was similar to but not identical to that of **2a**.⁴ Rather fascinating is the report of (+)-4*S*, 7*R*, 11*S*, 14*R*-cyclocinamide B¹⁴ (**3**) by Ireland from a Fijian sponge *Corticium* sp. (Homoslerophida, Plakinidae) which would be enantiomeric to **2b** if the C-36 substituents were identical.

The depletion of both sponge material and authentic samples of psymberin and cyclocinamide A in our repository necessitated a recollection effort. Our plan to obtain taxa containing both psymberin and cyclocinamide A was formulated based on the clarifying chemotype patterns shown in Table 1. The best Papua New Guinea collection site for the new samples appeared to be in the Amphlett vicinity of 9°43'S: 150°50'E to 9°14'S: 150°46'E. Thus, in May 2007, recollections were conducted at two locations yielding: (a) sample VII: Milne Bay 10°16'S: 150°47'E (coll. no. 07202, 76 g dry weight); and (b) sample VIII: Amphlett 9°14'S: 150°46'E (coll. no. 07208, 21 g dry weight). Parallel extraction of both collections followed by LC-MS analyses of the resultant crude mixtures indicated the presence of major metabolites as follows: sample VII - swinholide A¹⁵ and preswinolide A⁶ but no psymberin; and sample VIII - (+)-psymberin (**1a**) (MW 609, $[\alpha]_{\text{D}}^{27} = +23.4$, 3.2 mg, $1.5 \times 10^{-2}\%$ of the dry weight), microgram quantities of two psymberin analogs of MW 595 and MW 625 previously observed,⁷ and (+)-cyclocinamide A (**2a**) (MW 772, $[\alpha]_{\text{D}}^{27} = +32$, 0.5 mg, $2.4 \times 10^{-3}\%$ of the dry weight). Although additional work on sample VII was discontinued, the preceding results reaffirmed the expectations shown in Table 1 pertaining to the best collection sites for **1a** and **2a** containing samples. Once these outcomes had been obtained, portions of sponge VIII were shuttled to the Piel group at the University of Bonn for molecular genetics experiments paralleling those completed for pederin¹⁶ and findings will be published in the near future.

The isolation work on sample VIII proceeded in a multi-step fashion. The dichloromethane (coded XFD) and methanol (coded XFM) fractions showed potent activity in the soft agar colony forming disk diffusion assay (DDA).³ However, due to the paucity of the biological material, a traditional round of prefractionation was forgone. Both these extract fractions were directly subjected to semipreparative HPLC. The new sample of (+)-psymberin (**1a**) was obtained from the XFD and XFM fractions, while (+)-cyclocinamide A (**2a**) came from the XFM fraction. The identity of both compounds were confirmed from ¹H and ¹³C NMR data and included in the case of **2a** the additional diagnostic ESI-TOF-MS BrCl pseudomolecular ion cluster at $[M+Na]^+ m/z 772$.³ In the original structure elucidation of **2a**, the *i*Ser OH ¹H NMR shift was reported at $\delta_{\text{H}} 3.27$ from water suppression data, but further inspection of the published ¹H NMR spectra of **2a** reveals that in either DMSO-*d*₆ or DMSO-*d*₆/benzene-*d*₆, there are exchangeable proton signals at $\delta_{\text{H}} 6.05$ and $\delta_{\text{H}} 6.15$, respectively; however, these are not detected under CD₃OD conditions. The $\delta_{\text{H}} 6.01$ (d, ³*J* = 5 Hz) *i*Ser OH signal was clearly evident in the new sample of **2a** and consistent with observation that in (+)-cyclocinamide B (**3**) the *i*Ser OH occurs at $\delta_{\text{H}} 6.00$ (d, ³*J* = 4 Hz).¹⁴

The Marfey's method was employed to establish the absolute configuration of the chiral carbons in the new sample leading to the structure assigned as 4*S*, 7*S*, 11*S*, 14*S*-cyclocinamide A (**2a**). This began by treating the acid hydrolysate of **2a** with L-FDAA (*N*- α -(2,4-dinitro-5-fluorophenyl)-L-alanine amide)¹⁷ followed by HPLC analysis. The reference complexes were prepared by a similar derivatization employing standard amino acids. The HPLC conditions gave profiles in which each L-amino acid-FDAA complex eluted before the D-amino acid analogue, except for the β -amino acid *i*Ser whose L/D elution order was reversed.¹⁸ Acceptable retention time differences were observed for all HPLC runs. Thus, the comparative analysis by LC-MS of the derivatized hydrolysates obtained from **2a** vs. that of the standard amino acids was the basis for the all L-amino acid configuration assigned.

The solid tumor selectivity of (+)-cyclocinamide A (**2a**), originally reported as selective against colon-38 vs. L1210 cells in the DDA,³ has stimulated sustained interest in this unusual cyclic tetrapeptide core structure possessing the unique dipeptide side chain. The Grieco total synthesis of **2b** was relevant as a next step; unfortunately the small amount of material obtained was insufficient for further in vitro evaluation. Another development was that Ireland found (+)-cyclocinamide B (**3**) to be inactive against HCT-116 cells.¹⁴ Our further evaluation of **2a** revealed non-potent, modest solid tumor selectivity with inhibition zone sizes (90 μ g/disk) against HCT-125 (26 mm) and murine CFU-GM (16 mm) in the DDA, and the IC₅₀ against HCT-116 was > 10 μ g/mL. Thus, the previously encouraging solid tumor selectivity for **2a** against colon-38 was not seen against HCT cell lines for both **2a** and **3**.

The results presented above have added a new dimension to the chemical ecology of *P. aff. bulbosa* sponges. First, neither **1a** nor **2a** can be considered as marker compounds for *Psammocinia* because of their occurrence in other unrelated sponges. Second, a specific population of *P. aff. bulbosa* has now been shown to repeatedly be a source of **1a** and **2a**, meaning that further examination of the microbial communities associated with these distinct populations could be rewarding.²² Third, adjacent populations of material identified as *P. aff. bulbosa* (see Samples V and VI, Table 1) have been shown to vary considerably in their terpene vs. their PKS and NRPS type major metabolites. Finally, our re-examination of the bioactivity of **2a** offers additional clarifying data. Future efforts to prepare libraries of compounds based on the cyclocinamide framework both with and without the BrTrp moiety could be warranted.¹⁹

Experimental Section

General Experimental Procedures

¹H, ¹³C NMR experiments were run in Shigemi Tubes on a Varian UNITY-500 spectrometer (500 and 125 MHz for ¹H and ¹³C, respectively) using standard pulse sequences with residual solvent protons and carbons as references (DMSO-*d*₆: 2.50 and 39.51 ppm for ¹H and ¹³C, respectively). Mass measurements were obtained on a Mariner bench top ESI-TOF-MS. Crude extractions were obtained using an Accelerated Solvent Extractor (1500 psi, 100 °C). HPLC was performed with Phenomenex Luna reversed-phase semipreparative (10 mm \times 250 mm) and Altima reversed-phase analytical (5 mm \times 250 mm) C18 5 μ m columns.

Collection and Identification

The sponge samples were collected in May 2007 using SCUBA at depths of 30 - 60 ft. Coll. no. 07202 (sample VII) was collected from Milne Bay, Papua New Guinea (GPS = 10° 15.830 S: 150° 46.191 E) and coll. no. 07208 (sample VIII) was collected in the Amphlett region of Papua New Guinea (GPS = 9° 14.280 S: 150° 46.946 E). The collected specimen were globular in morphology with a small apical oscule. The grey-colored ectosome is composed of a neat reticulation of foreign material. The cream-colored endosome is a loose network of cored

primary fibers with sparse cored secondary fibers. The fine collagen filaments form a dense network in the endosome. Both collections were identified as a *Psammocinia* aff. *bulbosa* (Bergquist, 1995) by Dr. N. J. de Voogd. Voucher samples have been deposited at UCSC and Naturalis (RMNH); UCSC coll. no. 07202 = RMNH Por. 2980; UCSC coll. no. 07208 = RMNH Por. 2982. Topside and underwater photographs are also available from the Crews laboratory.

Extraction and Isolation

Biological material was handled using our standard laboratory protocol.¹ Crude extracts of the dried sponge (21 g dry weight) were obtained employing an Accelerated Solvent Extractor (ASE) to yield hexanes (XFH, 344.8 mg), CH₂Cl₂ (XFD, 214.6 mg), and CH₃OH (XFM, 839.1 mg) fractions. By LCMS, both the XFD and XFM showed trace amounts of (+)-psymberin (**1a**). The XFD was fractionated using semi-preparative RP-HPLC (25% aq to 100% CH₃CN with 0.1% formic acid over 30 min) to afford 1.7 mg of pure **1a** in fraction H17. The XFM was fractionated in a similar manner to yield 1.5 mg of **1a** fraction H7. Fraction XFM-H5 contained (+)-cyclocinamide A (**2a**) which was purified using analytical RP-HPLC (isocratic 30% aq CH₃CN with 0.1% formic acid) to yield 0.5 mg pure compound.

Hydrolysis and L-FDAA Derivatization of (+)-Cyclocinamide A (**2a**)

(+)-Cyclocinamide A (**2a**) (0.25mg) was hydrolyzed with 1 mL of 6 N HCl (0.1% phenol *w/v*)²⁰ for 4 h in a sealed thick walled vial at 110 °C. The hydrolysate was evaporated under nitrogen and then derivatized by treatment first with 100 μL of 1 M NaHCO₃ and second with 50 μL of *N*-α-(2,4-dinitro-5-fluorophenyl)-L-alaninamide (L-FDAA) solution (10 mg/mL in acetone).¹⁷ The reaction mixture was heated to 80 °C for 30 min, cooled to room temperature, and finally quenched with 50 μL of 2 N HCl. CH₃CN (300 μL) was then added for subsequent LC-MS analysis. Each standard amino acid (0.5mg) was derivatized under the same procedure with L-FDAA. For each reaction product, a linear gradient of 10% to 50% MeCN (0.1 M NH₄OAc, pH = 6) over 60 min was used to separate the derivatized products by LC-MS (Phenomenex Luna C1₈ column, 5mm × 250mm, UV 340 nm, flow rate 1 mL/min).¹⁴ Retention times of the derivatized hydrolysate were monitored by mass and UV (340 nm) and compared to that of the derivatized commercially available standard amino acids. The HPLC of co-injected 2:1 derivatized standard amino acid-FDAA diastereomer complexes gave profiles for DAP and Asp in which the L-amino acid-FDAA complex eluted before the D-amino acid analogue, while the β-amino acid, *i*Ser,¹⁸ demonstrated a D to L elution order.²³ As a racemic mixture of BrTrp was used for derivatization, we assumed the standard elution order to be L vs. D elution. This was identical to that observed by Ireland¹⁴ using similar HPLC analysis conditions. Finally, the optical properties of the new sample of **2a** ($[\alpha]_{\text{D}}^{27} = +32$, in MeOH) matches that of our original compound ($[\alpha]_{\text{D}}^{27} = +29$, in MeOH)³ in which L-BrTrp was established. Retention times for standard amino acid-FDAA derivatives: L-Asp 17.3 min, D-Asp, 20.0 min, D-*i*Ser 30.6 min, L-*i*Ser 31.3 min, L-DAP 49.1 min, L-5-BrTrp 49.8 min, D-DAP 50.1 min, D-5-BrTrp 53.2 min. Retention times for the FDAA hydrolysate derivatives of **2a**: L-Asp 17.3 min, L-*i*Ser 31.4 min, L-DAP 49.2 min, L-5-BrTrp 50.0 min.

Biological assays

The disk diffusion soft agar colony-forming assay (DDA)²¹ and IC₅₀ determinations⁷ were performed as previously described.

(+)-Psymberin (1a)— Spectroscopic data in accordance with published data.⁸

(+)-Cyclocinamide A (2a)—Spectroscopic data in accordance with published data.³

Swinholide A—Spectroscopic data in accordance with published data.¹⁵

Preswinholide A—Spectroscopic data in accordance with published data.⁶
