### Abstract

While developing novel catalysts for carbon-carbon or carbon-heteroatom coupling (N, O, or F), we were able to introduce tridentate NHC-amidate-alkoxide palladium(II) complexes. In aqueous solution, these NHC-Pd(II) complexes showed high ability for C-H activation of various hydrocarbons (cyclohexane, cyclopentane, dimethyl ether, THF, acetone, and toluene) under mild conditions.

### Keywords

NHC ligand; C-H activation; H/D exchange; Palladium complex; Intermolecular reaction

Carbon-carbon or carbon-heteroatom cross-coupling reactions catalyzed by transition metal catalysts have been widely investigated and established because of their significance in organic synthesis. In particular, homogeneous Pd catalysis has been well studied in the most powerful and versatile synthetic process such as Heck<sup>[1]</sup>, Suzuki<sup>[2]</sup>, Stille<sup>[3]</sup>, Sonogashira<sup>[4]</sup>, Negishi<sup>[5]</sup>, and Buchwald-Hartwig reactions<sup>[6]</sup>. However, these reactions have required alkenyl/aryl halide substrates. Alternatively, the more desirable direct functionalization of hydrocarbons via C-H bond activation has still remained a challenge in cross-coupling reactions.

In recent years, a substantial number of metal complexes that are able to selectively activate C-H bonds under mild conditions have been discovered.<sup>[7]</sup> In spite of these advances, practical catalysts for the C-H bond functionalization remain elusive, due to the requirement of high energy to break C-H bond and subsequent vulnerability of the metal-carbon bond. Additionally, the C-H bond activation is often inhibited by water or by the product eliminated from the metal complex during the reaction.<sup>[8]</sup>

Recently, *N*-Heterocyclic carbene (NHC) ligands, which are known to enhance  $\sigma$ -donor coordination, have shown improved behaviour toward C-H bond activation during the past several years.<sup>[9]</sup> A number of organometallic species at various oxidation states (Pd, Pt, Ru, and Ir) are stabilized by the use of NHC ligands, increasing the capability to obtain efficient catalysts for C-H activation.<sup>[10]</sup> However, most examples refer to intramolecular processes, while intermolecular or catalytic examples being rare. With these challenges in mind, we report herein the efficient C-H bond activation of hydrocarbons in aqueous solution

containing catalytic amounts of tridentate NHC ligand-Pd complex *via* H/D exchange as a probe for direct C-H functionalization. Such reactions have been studied in heterogeneous Pd catalytic systems but are rarely observed in homogeneous Pd systems.<sup>[11]</sup>

Recently, we have succeeded in preparing air-stable tridentate NHC-amidate-alkoxide ligand/palladium complex **1** from an amino alcohol.<sup>[12]</sup> We found that H/D exchange on benzene using D<sub>2</sub>O as both the solvent and deuterium source, occurred *via* C-H bond activation in the presence of Pd complex **1** and silver tetrafluoroborate. As shown in equation (1), the H/D exchange reaction was demonstrated with benzene (20  $\mu$ L), palladium complex **1** (5 mol %) and AgBF<sub>4</sub> in deuterium oxide (700  $\mu$ L) for 22 hours at 55 °C and 100 °C. The efficiency of the H/D exchange giving deuterated isotopomers showed significant enhancement, when temperature was increased from 55 °C to 100 °C. While evaluating H/D exchange with palladium complex **1** and AgBF<sub>4</sub>, we found that a dimeric structure **2** was present in the solution as indicated by <sup>1</sup>H-NMR spectroscopy.<sup>[13]</sup> At an elevated temperature, however, the concentration of monomeric species **3** was observed to be higher than complex **2**. Consequently, we confirmed that the H/D displacement *via* C-H bond activation worked well only in the presence of the monomeric species **3**. As shown in equation (2), NHC's ligand/palladium complex **1** was converted to the palladium complex **2** by treating with aqueous AgBF<sub>4</sub> for the C-H bond activation, and subsequently the monomer/dimer equilibrium process (**2**  $\rightleftharpoons$  **3**) took place depending on the temperature in the aqueous solution.<sup>[14]</sup> The higher efficiency of the H/D exchange process at 100 °C compared to 55 °C is attributable to the conversion of the catalyst into active mode **3** from complex **2** at the elevated temperature.

To further investigate the C-H activation of this class of Pd complexes, we extended the structural motifs of palladium to various tridentate ligands. To circumvent the dimerization of monomeric species in aqueous solution at low temperatures, we employed a methyl ether (**7a**) or benzyl ether (**7b**) group instead of the previously employed hydroxyl moiety as oxygen-site of the ligands (Scheme 1). Compounds **4a** and **4b** were prepared from ethanolamine and valinol, respectively.<sup>[15]</sup> Bromoacetylation of the amino ethers was followed by amide formation and N-alkylation with benzimidazole to yield **5a** and **5b**. The benzimidazole salts **6a** and **6b** were obtained by allowing **5a** and **5b** to react with CH<sub>3</sub>I in THF. For the coordination of NHC's to palladium, metal exchange was carried out through a silver NHC complex.<sup>[16]</sup> N-Methyl iodide salts **6a** and **6b** were reacted with Ag<sub>2</sub>O to give silver NHC complexes, and subsequent treatment of the silver compounds with PdCl<sub>2</sub>(CH<sub>3</sub>CN)<sub>2</sub> in CH<sub>3</sub>CN provided the desired complexes **7a** and **7b** in 79 and 72% yields, respectively. The structures of Pd/ligand complexes **7a** and **7b** were further confirmed by the molecular ion peaks (ESI-MS) at *m/z* 388.0029 [M<sup>+</sup>] (calcd: 388.0044) and *m/z* 506.0813 [M<sup>+</sup>] (calcd: 506.0827).

In addition, we designed an O-C-N tridentate ligand system, an example of which is the alkoxy-NHC-amidate ligand/palladium complex **11** (Scheme 2). Amide compound **9** was easily derived from aniline and bromoacetyl bromide. By means of N-alkylation with benzimidazole and compound **9**, the benzimidazole-amide adduct was obtained in DMF solution, which after second N-alkylation with iodoethanol gave the iodine salt **10** in 62% yield for two steps. Subsequently, construction of alkoxy-NHC-amidate ligand/palladium complex **11** was successfully accomplished by treatment with half an equivalent of  $\text{Ag}_2\text{O}$  and one equivalent of  $\text{PdCl}_2(\text{CH}_3\text{CN})_2$  sequentially in  $\text{CH}_3\text{CN}$  solution at room temperature.

First, to optimize the H/D exchange reaction conditions, various reaction temperatures and catalyst loadings were screened with Pd complexes **8a**, **8b** and **12** for benzene in  $\text{D}_2\text{O}$ . The H/D exchange can be conveniently monitored by  $^1\text{H}$  NMR spectroscopy through observation of the decreasing proton signals of benzene in the aqueous phase relative to the poly(dimethylsiloxane) as an external reference standard. Before H/D exchange,  $\text{AgBF}_4$  was added into a MeCN solution of Pd complexes **7a**, **7b** and **11** to remove Cl anion, so that Pd complexes **8a**, **8b**, and **12** could be ready for the C-H activation. In addition, unreacted  $\text{AgBF}_4$  and  $\text{AgCl}$  were removed by a celite column. In  $\text{D}_2\text{O}$  solution, the MeCN  $^1\text{H}$ -signal shifted from 2.06 ppm (free MeCN in  $\text{D}_2\text{O}$ ) to 2.16 ppm as well as broadening of the signal indicated that there was weak interaction between MeCN and Pd metal.

As shown in Table 1, we found that the reaction temperature could be lowered to 55 °C without causing a significant decrease in the extent of deuterium incorporation relative to that observed in reactions run at 100 °C (entry 3). Interestingly, we discovered that at 55 °C increasing the catalyst loading beyond 1.7 mol% (entry 4) did not lead to a detectable increase in deuterium incorporation. While use of less catalyst (entries 1 and 2) lead to a decrease in the extent of H/D exchange, 1.7 mole% is apparently enough to saturate the system and achieve optimum conversion. In addition, longer reaction times may not affect the catalytic cycle dramatically (entry 3). When the ligand **8b** possessing a benzyl ether group was utilized, deuterium incorporation slowed down somewhat at 55 °C (entry 5), however deuterium incorporation was barely seen at an elevated temperature (100 °C) due to deactivation of **8b** by coordination between palladium and benzyl aromatic C-H intramolecular activation to generate **8c** (Equation 3).<sup>[17]</sup> Moreover, alkoxy-NHC-amidate ligand/palladium complex **12** gave the lowest level of deuterium incorporation into benzene at 55 °C because of the steric hindrance of the phenyl group as well as the existence of dimer/monomer equilibrium in aqueous solution (Equation 4).<sup>[14]</sup> This result wherein the efficiency of the H/D exchange showed significant enhancement at a higher temperature is in accordance with behaviour of the active catalyst derived from **1** (Equation 1).

(3)

Additionally, in an experiment designed to study the time dependence of the deuterium displacement, a solution of benzene with catalyst **8a** in D<sub>2</sub>O was heated to 55 °C and monitored by <sup>1</sup>H NMR spectroscopy. As shown in Figure 1(A), over a period of 22 hours, the resonances for the benzene (δ 6.71 at 55 °C) disappeared without any significant change in the signal intensities of the other resonances. Furthermore, to unequivocally establish C-H activation with Pd complex, we also probed deuterium-proton displacement between C<sub>6</sub>D<sub>6</sub> and H<sub>2</sub>O at 55 °C and H/D incorporation was monitored by <sup>2</sup>H NMR spectroscopy. As shown in Figure 1(B), the signal for benzene-d<sub>6</sub> decreased in intensity over a period of 16 h. Overall conversion of C<sub>6</sub>D<sub>6</sub> to C<sub>6</sub>H<sub>6</sub> by 3.6 μmol of **8a** was 75%, which is lower than the percent of conversion of C<sub>6</sub>H<sub>6</sub> to C<sub>6</sub>D<sub>6</sub> (89.5% in 6 h, entry 2 in table 1) as expected.

On the basis of these results, various organic substrates were investigated to explore the feasibility of the H/D exchange reaction with palladium NHC-ligand complex **8a**. In general, effective multiple deuterium incorporation into the alkyl C-H was observed with D<sub>2</sub>O as both the solvent and deuterium source. Table 2 lists the organic substrates examined and their corresponding extents of deuterium incorporation. Catalyst **8a** showed deuteration ability for a wide range of molecules including saturated hydrocarbons, ethers, and ketones. Remarkably, the catalyst was also capable of C-H activation of saturated hydrocarbons such as cyclohexane and cyclopentane, and excellent total deuterium incorporation (96 ~ 97%) was observed (entries 1 ~ 4). Recently, there have been a few examples for the H/D exchange of cyclohexane and cyclopentane, in which efficient thermal catalysis was carried out by Ir or Pt species using deuterated organic solvents or D<sub>2</sub> as the deuterium source.<sup>[18]</sup> These C-H activations were developed with modest conversions, and they had additional drawbacks such as air/water sensitivity of the metal catalysts and high reaction temperature requirement. On the contrary, our palladium complex **8a** appeared to be superior for C-H activation of saturated hydrocarbons with significant air/water stability.

Ether compounds such as THF and diethyl ether showed lower levels of D-incorporation compared to aromatic and saturated hydrocarbons, however we observed that it was also a facile process with catalyst **8a** under conditions of higher temperatures and longer reaction times (entries 6 and 8) with increased catalyst loading (entry 9). To our knowledge, there are only few examples for the H/D exchange of THF, which were effected by Ir catalysis at lower levels of D-incorporation at longer reaction times and higher temperatures.<sup>[19]</sup> Although the selective C-H activation for the α- and β-positions of THF and diethyl ether was not examined under these conditions, we demonstrated H/D exchange for these ether compounds with palladium complexes. These findings were quite similar to the case of H/D exchange with ketone as the substrate. While deuterium was incorporated into acetone at higher initial conversion values than the ethers, an increase in the three aforementioned reaction variables led to a significant improvement of percent D-incorporation for this substrate (entries 10 ~12). Also, we examined the deuterium incorporation of toluene in D<sub>2</sub>O to elucidate the possibility of selective C-H activation for aryl and alkyl groups. Similarly to other examined substrates, toluene showed high H/D conversions (95 ~ 97%) at 100 °C (entry 14), however we were not able to observe selective C-H activation for CH<sub>3</sub> (95% in 6 h) or C<sub>6</sub>H<sub>5</sub> C-H bonds (95% in 6 h).

(5)

Based on these studies, which tested the possibility of direct oxidation of a  $sp^2$  C-H bond,  $C_6H_6$ , was added to a reaction mixture of **2** (10 mol %) in 30%  $H_2O_2$  solution (Equation 5). We detected the oxidation product of phenol via C-H activation to afford phenol as a product.

In summary, we have demonstrated efficient and strong C-H activation with water soluble NHC-Pd(II) complexes that showed efficient H/D exchange of various organic substrates under  $D_2O$  under mild conditions (55 °C or 100 °C). Importantly, the catalytic reaction was not inhibited by coordination of water to Pd. Strongly electron donating groups such as NHC, amide N, and O would increase the electron density of Pd, allowing a weak interaction between electrophilic Pd and water. In addition, we were able to obtain a preliminary result for the direct functionalization in aqueous media. This independent character of the developed catalysts from water and polar solvents can open up a new avenue in Pd(II) catalysis. Accordingly, utilization of this system for the incorporation of deuterium and other useful functional groups into the C-H bonds of numerous classes of organic compounds will be extensively pursued and reported in due course.

## Experimental Section

### Catalytic H/D exchange reaction

Pd cation compounds were prepared when required. Catalyst (**7a**, **7b**, or **11**) and 1.5 eq of  $AgBF_4$  were stirred in 2 mL of MeCN solution for 30 minutes. After passing through celite column, the filtrate was dried in a rotary evaporator. The dried compound was dissolved in 0.7 mL of  $D_2O$  and placed in a J-Young NMR tube with an external standard capillary consisting of  $C_6F_6$  solution with the poly(dimethylsiloxane). Then the hydrocarbon substrate (20  $\mu$ L) was added in  $D_2O$  solution. The resulting mixture was heated at 55 °C/100 °C. Deuteration levels were monitored by  $^1H$  NMR using an external capillary standard consisting of a solution of the poly (dimethylsiloxane).

### Oxidation of Benzene (Equation 5)

Pd cationic compound **2** was prepared when required. The catalyst **1** (2 mg, 0.5 mol%) and  $AgBF_4$  (1.5 equiv.) were stirred in 2 mL of MeCN solution for 30 minutes. Then filtrate was dried in a rotary evaporator after passing through celite column. The dried compound was dissolved in 0.2 mL of  $H_2O$ . Then 0.2 mL of  $H_2O_2$  and 0.1 mL of  $C_6H_6$  was added to the aqua solution. The resulting mixture was heated at 60 °C for 20 hours. After the catalytic reaction, 2  $\mu$ L of pyridine for the internal reference and 0.2 mL of  $D_2O$  were added. Production of 16 equivalent of phenol was detected by WET1D NMR technique.
