Abstract

Background—Curcumin, a natural polyphenol product of the plant *Curcuma longa*, has been shown to inhibit the growth and progression of colorectal cancer; however, the anticancer mechanism of curcumin remains to be elucidated.

Materials and Methods—Colorectal cancer cells were treated with curcumin and changes in proliferation, protein and mRNA levels were analyzed.

Results—Curcumin inhibited proliferation of colorectal cancer cells. This effect was mediated by inhibition of mammalian target of rapamycin (mTOR) signaling as evidenced by decreased phosphorylation of downstream effectors of mTOR complex 1 (mTORC1), p70S6K and 4E-BP1. Curcumin decreased total expression of mTOR, Raptor and Rictor protein and mRNA levels. Surprisingly, curcumin induced phosphorylation of Akt(Ser 473); this effect may be attributed to a decrease in levels of the PHLPP1 phosphatase, an inhibitor of Akt.

Conclusion—Our data suggest that curcumin, a natural compound, may exert its antiproliferative effects and inhibition of mTOR signalling and thus may represent a novel class of mTOR inhibitor.

Keywords

Curcumin; colorectal cancer; mTOR; Raptor; Rictor; Akt; PHLPP

Curcumin (diferuloylmethane), a component of the spice turmeric derived from the roots of the plant *Curcuma longa*, has been used through the ages for its antioxidant, anti-inflammatory, chemopreventive and chemotherapeutic effects (1). Curcumin can suppress tumor initiation (by reducing proliferation and inducing apoptosis), promotion and metastasis in a variety of malignant cells (2,3). We have previously shown that one mechanism for the chemotherapeutic effects of curcumin on colorectal cancer (CRC) is through inhibition of neurotensin-induced expression and secretion of the chemokine, interleukin-8 (IL-8), subsequently reducing cell migration (4).

The phosphatidylinositol-3-kinase (PI3K)-Akt-mammalian target of rapamycin (mTOR) pathway is a key regulator of growth and survival in response to cellular stress (5). Activation of Class I PI3K, by activating mutations or loss of the tumor suppressor protein phosphatase and tensin homologue (PTEN), is associated with growth and progression of a number of types of cancer including CRC (6,7). Our laboratory has shown that inhibition of PI3K/Akt pathway components reduces growth, increases apoptosis and sensitivity to chemotherapy, and reduces the metastatic capability of CRC (8-12).

The mTOR kinase lies downstream of Akt and positively regulates phosphorylation of p70 S6 kinase (S6K) and eukaryotic initiation factor 4E (eIF4E) binding protein 1 (4E-BP1) (5). Rapamycin treatment results in hypo-phosphorylation of S6K and 4E-BP1, thus causing blockade of cap-dependent mRNA translation (5). Raptor and Rictor are components of mTOR complexes 1 and 2 (mTORC1 and 2) respectively, both exhibiting distinct cellular functions. The activation status of Akt regulates mTORC1 activity, thus placing it downstream in the PI3K signaling cascade. Inhibition of mTORC1 by rapamycin leads to activation of a negative feedback loop *via* S6K and insulin-like growth factor-1 receptor, which results in feedback activation of Akt (5,13). In contrast, mTORC2 directly phosphorylates Ser 473 in the C-terminal hydrophobic motif of Akt, which is necessary for full activation of the latter (5). Thus, mTOR complexes act both upstream and downstream of Akt. Moreover, the PHLPP (PH domain leucine-rich repeats protein phosphatase) family of Ser/Thr protein phosphatases have recently been identified as the phosphatases responsible for dephosphorylating Akt directly (14,15). Recent evidence indicates that PHLPP 1 and 2 act as tumor suppressors in CRC; their expression is lost or reduced in 78% and 80% of CRCs respectively (16).

Curcumin inhibited Akt phosphorylation in certain cancer cells (17,18) and has also recently been shown to inhibit mTOR signaling at relatively low concentrations in rhabdomyosarcoma, prostate and breast cancer cells (19,20). It has previously been shown that curcumin inhibited proliferation of CRCs (21), and we have previously shown that curcumin reduced neurotensin-mediated migration of CRCs (4). In our current study, we investigated whether curcumin inhibits mTOR signaling in CRC since mTOR functions as a central regulator of proliferation and migration.

Materials and Methods

Cell culture

HCT116 CRC cells, obtained from the American Type Culture Collection (Manassas, VA, USA), were maintained in McCoy's 5A medium supplemented with 10% fetal bovine serum (FBS). KM20 CRC cells, obtained from Dr. Isaiah Fidler (M. D. Anderson Cancer Center, Houston, TX, USA), were maintained in minimum essential media (MEM) with 10% FBS. Curcumin was purchased from Sigma (St. Louis, MO, USA); a 25 mM stock solution in ethanol was maintained at -20°C .

Cell proliferation assays

A cell proliferation assay measuring total DNA content was performed using crystal violet dye. Briefly, cells were plated in 96-well plates and allowed to adhere overnight, then treated with different doses (0-100 μM) of curcumin or vehicle (70% ethanol). After 24, 48, and 72 h, the media were removed and cells were fixed and stained with a solution containing 20% methanol and 0.5% crystal violet. After rinsing and drying, the dye was solubilized with 15% acetic acid and the absorbance was read at 570 nm.

Western blotting

Western blotting was performed as described previously (8). In Fig. 2, HCT116 cells were serum starved overnight and treated with 25 μ M curcumin for 2 hours, followed by stimulation with 20 ng/ml EGF for 45 minutes, prior to cell lysis. Antibodies used were β -Actin (Sigma, St. Louis, MO, USA); p-mTOR (Ser 2448), mTOR, Raptor, Rictor, p-p70S6K (Thr389), p70S6K, pAkt (Ser 473), Akt, p-4E-BP1 (Thr 37/46) and 4E-BP1 (Cell Signaling, Danvers, MA, USA); PHLPP1 (Bethyl Laboratories, Montgomery, TX, USA). Data are representative of three independent experiments with similar results.

RNA isolation and quantitative RT-PCR

HCT116 cells were treated with curcumin (0-100 μ M) for 6 h and RNA was isolated using RNEasy kit (Qiagen, Valencia, CA, USA) according to the manufacturer's protocol. Real-time PCR for mTOR (FRAP1), Rictor, Raptor, and 18S was performed as described elsewhere (22). Separate tubes (singleplex) one-step RT-PCR was performed with 80 ng RNA for all target genes and endogenous control. The reagent used was TaqMan one-step RT-PCR master mix reagent kit (Foster City, CA, USA) the cycling parameters for one-step RT-PCR were: reverse transcription 48°C for 30 min, AmpliTaq activation 95°C for 10 min, denaturation 95°C for 15 s and annealing/extension 60°C for 1 min (repeat 40 times) on Applied Biosystems PRISM 7000 (Applied Biosystems, Foster City, CA). Duplicate C_T values were analyzed in Microsoft Excel using the comparative $C_T(\Delta\Delta C_T)$ method as described by the manufacturer. The amount of target ($2^{-\Delta\Delta C_T}$) was obtained by normalizing to endogenous reference (18S) and relative to a calibrator (one of the experimental samples).

Statistical analysis

Dose effect of curcumin on HCT116 and HT29 cell proliferation (Fig. 1) and on mRNA (Fig. 3) were analyzed, separately for each incubation time and each kind of cancer cells (Fig. 1) or each kind of protein (Fig. 3), using one-way classification analysis of variance. The dose was assessed at the 0.05 level of significance. Comparisons of each dose with the control (no curcumin) were conducted using Fisher's least significant different procedure with Bonferroni adjustment for the number of comparisons. Statistical computations were carried out using PROC GLM in SAS[®], Release9.1 [R1].

Results

Curcumin inhibits the growth of human CRC cells in a time and dose-dependent manner

Curcumin inhibits growth of a number of types of cancer (2,3). Based on these studies, we first determined the effects of curcumin on the proliferation of CRC cells. The doses of curcumin used were comparable to these in previous studies. HCT116 and KM20 cells were treated with curcumin (0-100 μ M) for 72 h. As shown in Figure 1A, curcumin significantly reduced proliferation of both cell lines, although with different effects. Curcumin (12.5 μ M) significantly reduced cell numbers as early as 24 h. It is interesting to note that this dose was cytostatic in KM20 cells, while being cytotoxic in HCT116 cells as approximately 90% of the cells were dead by 72 h. High-dose curcumin (50-100 μ M) was clearly cytotoxic in both CRC cell lines, with a significant decrease in cell number at the earliest time point (24 h).

To further confirm the effects of curcumin on CRC proliferation, we utilized a neutral red (NR)-based cytotoxicity assay, which assesses the ability of viable cells to uptake NR, a cationic dye that penetrates cell membranes and accumulates in lysosomes. As shown in Figure 1B, the effects of curcumin were evident as early as 2 h after treatment with a low dose (5 μ M) of curcumin.

Curcumin inhibits EGF-stimulated phosphorylation of S6K, 4E-BP1 and mTOR

Recent evidence has implicated mTOR as a central regulator of proliferation in various normal and malignant cells (5). Several proteins regulated by mTOR such as cyclin D1, ornithine decarboxylase, NF- κ B, Akt and PKC, are also targeted by curcumin (1,2). Thus, we hypothesized that curcumin may reduce proliferation by inhibiting the mTOR signaling pathway. After an overnight serum starvation, HCT116 cells pre-treated with curcumin for 2h were treated with EGF for 45 min to stimulate the PI3K/Akt/mTOR pathway. As shown in Figure 2, curcumin inhibited EGF-stimulated phosphorylation of mTOR (Ser 2448; a site regulated by Akt), as well as S6K (Thr 389; a site regulated by mTOR) and 4E-BP1 (Thr 37/46; both sites regulated by mTOR), two well-characterized downstream effector molecules of mTORC1. Interestingly, total protein levels of both Rictor and Raptor significantly increased with EGF treatment. Curcumin reduced total protein levels of mTOR, Raptor and Rictor. The latter effect was noted both in the presence and absence of EGF. Surprisingly, curcumin induced phosphorylation of Akt (Ser 473), while reducing the total protein levels of Akt. Therefore, we conclude that curcumin inhibits downstream components of the mTOR signaling pathway, while inducing Akt phosphorylation.

Curcumin suppresses mTOR, Rictor and Raptor protein and mRNA levels, but induces Akt (Ser 473) phosphorylation due to a decrease in PHLPP1 protein level

In order to confirm the effects of curcumin on mTORC1 and mTORC2 expression in CRC cells, we treated HCT116 cells with increasing doses of curcumin (0-100 μ M) and performed Western blotting and quantitative RT-PCR analysis. As shown in Figure 3, mTOR, Raptor and Rictor mRNA levels decreased in a dose-dependent manner with curcumin treatment. Similarly, curcumin also reduced mTOR, Raptor and Rictor protein expression in a dose-dependent manner (Figure 4); this effect was noted as early as 2 h (data not shown). Similar results were noted with curcumin treatment of KM20 cells (data not shown).

To determine downstream effectors of curcumin-mediated inhibition of mTOR complex components, we next examined levels of phosphorylated and total p70S6K, 4E-BP1 and Akt. As shown in Figure 4, activation of S6K and 4E-BP1 was inhibited by curcumin, while total levels of both proteins were essentially unchanged. Surprisingly, curcumin induced Akt (Ser 473) phosphorylation in a dose-dependent manner despite a significant decrease in Rictor expression. Total Akt levels also decreased upon treatment with moderate doses (50 μ M) of curcumin, which is consistent with effects noted in other types of cancer cells (23-25). One possible mechanism for an increase in pAkt(Ser 473) is through inhibition of the constitutively active Akt phosphatase, PHLPP. In this regard, we found that PHLPP1 protein levels were reduced by low doses of curcumin. Therefore, curcumin produced a dose-dependent decrease of mTOR, Raptor and Rictor mRNA and protein levels. However, curcumin resulted in a dose-dependent induction of Akt(Ser 473) phosphorylation; this effect may be attributed to a decrease in PHLPP1 protein levels.

Discussion

mTOR has been recognized as a key therapeutic target for the treatment of several types of cancer since it is a central hub for regulation of cellular processes that are critical for growth (such as proliferation) and progression (such as migration) of cancer (5). We showed that curcumin reduced neurotensin-mediated migration of CRCs (4), and here we show that curcumin reduced proliferation of CRC cells in a dose- and time-dependent manner. This prompted us to further study the effect of curcumin on mTOR signaling since the anticancer mechanism of curcumin remains to be fully elucidated. To this end, we found that curcumin reduced expression of mTOR, Raptor and Rictor protein and mRNA levels, as well as downstream mTORC1-mediated phosphorylation of p70S6K and 4E-BP1. Therefore, the

antiproliferative effects of curcumin in CRC may be mediated by inhibition of the mTOR signaling pathway.

In support of our findings, several recent studies have shown that curcumin targets the mTOR pathway and represents a powerful therapeutic tool for use against cancer dependent on elevated PI3K signaling (3,26-29). Curcumin down-regulates expression of the p53 ubiquitin E3 ligase, MDM2, partially through inhibition of the mTOR pathway in prostate cancer (26). Furthermore, curcumin induces autophagy in gliomas *via* inhibition of mTOR and ERK signaling (27,28). It was recently shown that curcumin inhibits mTORC1 signaling by directly inhibiting the kinase activity of mTORC1 due to disruption of the mTOR-Raptor interaction in rhabdomyosarcoma (29). Taken together with our findings, this suggests that curcumin may exert its inhibitory effect on mTOR signaling by reducing total expression of mTOR complex components as well as preventing association of the components from forming stable complexes. As compared to rapamycin, which is a specific inhibitor of mTORC1 in most cells, our findings suggest that curcumin is a novel class of mTOR inhibitor that inhibits both mTORC1 and mTORC2 in CRC cells.

Rictor is a critical component of mTORC2 that is required for assembly and activity of the PDK-2 kinase (mTORC2). Therefore, lower Rictor levels would be expected to reduce the phosphorylation of Akt (Ser 473). Surprisingly, curcumin induced Akt (Ser 473) phosphorylation in a dose-dependent manner despite a significant decrease in Rictor levels. Total Akt levels also decreased slightly upon treatment with moderate doses (50 μ M) of curcumin, which is consistent with other published studies (16-18). One possible mechanism for an increase in pAkt (Ser 473) could be through inhibition of the constitutively active Akt phosphatase, PHLPP1. PHLPP1 protein levels were found to be reduced by curcumin even at low doses. There are no studies showing the effects of curcumin on PHLPP, although it has been shown to have variable effects on other types of phosphatases. Another factor contributing to the increased Akt (Ser 473) phosphorylation may be feedback activation of Akt *via* the S6K-IGF-1R-mediated negative feedback loop upon mTORC1 inhibition by curcumin. Therefore, curcumin may induce Akt (Ser 473) phosphorylation *via* a novel PHLPP1 down-regulation mechanism despite a significant decrease in levels of the mTORC2 kinase component, Rictor.

Most chemotherapeutic agents not only induce apoptosis in cancer cells, but also severely damage normal host cells. Curcumin, a natural compound that is part of daily diets in several countries, has been proven to be a safe product since it preferentially induces apoptosis in highly proliferating tumor cells rather than normal ones (1). Doses up to 8-10 g may be administered daily to patients for 3 months without toxicity (2). In fact, consumption of curcumin as part of the daily diet in several Asian countries has been suggested to be the reason for their lower rate of CRC compared to developed countries (1,2). Moreover, curcumin undergoes intestinal metabolism, particularly glucuronidation and sulphation, in addition to first-pass metabolism in the liver. Therefore, the gastrointestinal tract could be a preferential target for this compound due to greater exposure to unmetabolized curcumin upon oral administration (30). Due to its high potency and efficacy against cancer both *in vitro* and *in vivo*, as well as its safety for use in humans, curcumin is currently being evaluated in phase III clinical trial as part of a combination treatment for metastatic CRC.

In summary, we show that the antiproliferative effect of curcumin may be mediated by inhibition of mTOR signaling. Curcumin produces a dose-dependent decrease of mTOR, Raptor and Rictor mRNA and protein levels. Surprisingly, curcumin results in a dose-dependent induction of Akt (Ser 473) phosphorylation; this effect may be attributed to a dose-dependent decrease in PHLPP1 protein levels. Finally, curcumin represents a new class of mTOR inhibitor that can inhibit both mTORC1 and mTORC2.
