**Abstract:** In this study, antibacterial characteristic of silver/poly (lactic acid) nanocomposite (Ag/PLA-NC) films was investigated, while silver nanoparticles (Ag-NPs) were synthesized into biodegradable PLA via chemical reduction method in diphasic solvent. Silver nitrate and sodium borohydride were respectively used as a silver precursor and reducing agent in the PLA, which acted as a polymeric matrix and stabilizer. Meanwhile, the properties of Ag/PLA-NCs were studied as a function of the Ag-NP weight percentages (8, 16, and 32 wt% respectively), in relation to the use of PLA. The morphology of the Ag/PLA-NC films and the distribution of the Ag-NPs were also characterized. The silver ions released from the Ag/PLA-NC films and their antibacterial activities were scrutinized. The antibacterial activities of the Ag/PLA-NC films were examined against Gram-negative bacteria (*Escherichia coli* and *Vibrio parahaemolyticus*) and Gram-positive bacteria (*Staphylococcus aureus*) by diffusion method using Muller–Hinton agar. The results indicated that Ag/PLA-NC films possessed a strong antibacterial activity with the increase in the percentage of Ag-NPs in the PLA. Thus, Ag/PLA-NC films can be used as an antibacterial scaffold for tissue engineering and medical application.

**Keywords:** antibacterial activity, silver nanoparticles, biodegradable, poly (lactic acid), Muller–Hinton agar

## Introduction

Biocompatible and biodegradable polymers became very important and gained a lot of attention from both biomedical and ecological outlooks in the past decade.<sup>1</sup> At that time, synthetic biodegradable polymers were given a lot of attention because they could be used in important biomedical applications approved by the US Food and Drug Administration. Among the most popular and important biodegradable polymers are aliphatic polyesters<sup>2–5</sup> such as poly (3-hydroxybutyrate), poly (ε-caprolactone), poly (glycolic acid), and poly (lactic acid) (PLA), whereby PLA received the most attention due to its renewable resources,<sup>6</sup> biodegradation, biocompatibility, as well as excellent thermal and mechanical properties, and superior transparency of the processed materials.<sup>7</sup> Moreover, PLA is widely used in various medical applications such as surgical implants, tissue culture, resorbable surgical sutures, wound closure, and controlled release systems.<sup>2–5</sup> PLA produced from renewable resources is a linear aliphatic thermoplastic, which is readily biodegradable through hydrolytic and enzymatic pathways.<sup>8–10</sup> More importantly, PLA is an immunologically inert synthetic polymer,<sup>11,12</sup> and for this reason, it was chosen for designing a composition of tissue engineering scaffold in the present study.<sup>13,14</sup>

As they possess strong antibacterial properties and low toxicity, silver nanoparticles (Ag-NPs) and their compounds have been studied for many years not only for their low toxicity, but also for their antibacterial activity.<sup>15–18</sup> Yeo et al found that fibers containing silver showed excellent antibacterial properties.<sup>19</sup> Meanwhile, studies conducted on Ag-NPs using different polymers have been reported; these include the synthesis in poly vinyl pyrrolidone,<sup>20</sup> poly (vinyl alcohol),<sup>21</sup> hyper branched polyurethane<sup>22</sup> and poly acrylonitrile<sup>23</sup> to give discrete Ag-NPs. There are significant variations in the average sizes and shapes of the Ag-NPs when the polymers were used due to the different chemical structures and Ag/polymer interactions. Natural polymers have also attracted great interest, because they are biocompatible and non-toxic in most cases. Among the few stabilizers or matrices investigated for metal nanoparticles are chitosan,<sup>24</sup> starch,<sup>25</sup> cellulose,<sup>26</sup> and natural rubber.<sup>27</sup>

In this work, Ag/PLA-NC films were synthesized using AgNO<sub>3</sub> and sodium borohydride as silver precursor and reduction agent respectively in the PLA as a polymeric matrix in the diphasic solvent. The antibacterial activity of the Ag/PLA-NCs was also determined.

## Materials and methods

### Materials

All reagents in this work were of analytical grades and used in their original form without any purification; in particular, PLA (density: 1.24 g/mL, >98%), which was supplied by Nature Works 4060D (USA). AgNO<sub>3</sub> (99.98%) and NaBH<sub>4</sub> (98.5%) were obtained from Sigma-Aldrich (USA). N, N-dimethyl formamide (DMF) (99.0%) and dichloromethane (99.0%) were purchased from Merck (Germany). Phosphate buffer saline (PBS) (pH = 7.00) was supplied by JT Baker (Germany). All the aqueous solutions were made using double distilled water (DD-water).

### Synthesis of Ag/PLA-NCs by using NaBH<sub>4</sub>

PLA was dissolved in a mixed solvent of DMF and CH<sub>2</sub>Cl<sub>2</sub> (1/9 v/v) to achieve a concentration of 10 wt%, and certain amounts of AgNO<sub>3</sub> (0.8, 1.6, and 3.2 g) were added to the solution. The AgNO<sub>3</sub>/PLA solution was observed to be colorless when stirred for 48 hours in an ice water bath, and then 10 mL of NaBH<sub>4</sub> aqueous solution (molar ratio of AgNO<sub>3</sub>/NaBH<sub>4</sub> was 1:2) was added dropwise into AgNO<sub>3</sub>/PLA solution under vigorous stirring at the same temperature for 2 hours. The formation of the Ag-NPs started in the aqueous phase, but later the nanoparticles transferred

to the organic phase due to the presence of van der Waals interactions between the hydroxyl groups of the PLA and the partial charges surrounded in the surface of the Ag-NPs.<sup>28,29</sup> The organic phase containing stable Ag-NP colloid was separated from the aqueous phase and shaken with DD-water twice to remove any silver ions. After drying at room temperature, the Ag/PLA-NC films were dissolved in CH<sub>2</sub>Cl<sub>2</sub> and dried using solution-casting technique after ultrasonication for 15 minutes.

### Silver ions release

For determination of silver ions release, the Ag/PLA-NC films were cut into (1.0 cm × 1.0 cm) pieces with approximately 3.0 mg in weight. The *in vitro* release of silver was carried out in 10 mL of PBS. The samples were incubated at 37°C under water shaker at 70 rev min<sup>-1</sup>. The concentration of silver in the solution withdrawn from the test medium at the fixed time intervals was determined using atomic absorption spectroscopy.

### Evolution of antibacterial activity

*In vitro* antibacterial activity of the samples was evaluated using disc diffusion method with Muller–Hinton agar and a determination of inhibition zone in millimeters (mm) which conforms to the recommended standards of the National Committee for Clinical Laboratory Standards. The antibacterial activity of Ag/PLA-NC films was scrutinized against Gram-negative bacteria, *Escherichia coli* ATCC 13706 and *Vibrio parahaemolyticus* ATCC 17802, and Gram-positive bacteria, *Staphylococcus aureus* ATCC 12600, at different percentages of Ag-NPs in the polymeric matrix. In order to recover the lyophilized culture, the desired culture contained in the plastic bead was aseptically transferred into a tube containing 5 mL of nutrient broth and maintained in an incubator at 37°C for 24 hours for bacteria and 25°C for 72 hours for mold. The working stock cultures were maintained on the tripton soy agar (TSA) and potato dextrose agar (Oxoid Ltd, England) slants for the bacteria and mold, respectively, at 4°C in a refrigerator. A single bacterial colony for each microorganism was used to inoculate 100 mL sterile tripton soy broth, which was grown aerobically overnight at 37°C in a rotary shaker at 90 rev min<sup>-1</sup> for 18 hours and used as the microbial culture. The initial concentration of the cultures was 4.48 × 10<sup>7</sup> for *E. coli*, 7.61 × 10<sup>6</sup> for *S. aureus*, and 7.24 × 10<sup>6</sup> for *V. parahaemolyticus*, and these were determined using the solid agar plate test. Square samples (1.5 × 1.5 cm) of PLA and Ag/PLA-NC films containing different percentages of

Ag-NPs were sterilized by dipping them in ethanol alcohol for 15 minutes and placed on the surface of TSA which was seeded by 1.0 mL of microorganism culture. The plates were inoculated at 37°C for 24 hours. The diameters of the inhibition zone around the film specimen were used to determine the antimicrobial activity of each film sample, and the average of 3 replications was recorded.

## Characterization methods and instrumental

The synthesis of nano Ag/PLA was characterized using x-ray diffraction (XRD), transmission electron microscopy (TEM), UV-visible (UV-vis) spectroscopy, Fourier transform infrared (FT-IR) spectroscopy, and atomic absorption spectrometer. Meanwhile, the structure of the Ag/PLA produced was studied using the XRD (Philips, X'pert, Cu Ka) and were recorded at a scan speed of 4°/min. The TEM observations were carried out using a Hitachi H-7100 electron microscope, whereas the particle size distributions were determined using the UTHSCSA Image Tool version 3.00 program. The UV-vis spectra were recorded over a range of 300–700 nm with an H.UV.1650PC (SHIMADZU).B UV-vis spectrophotometer. FT-IR spectra were recorded over the range of 400–4000 cm<sup>-1</sup> with a Perkin Elmer 1650, FT-IR spectrophotometer. The released Ag<sup>+</sup> concentration in the PBS solution was determined using the atomic absorption spectrometer (Thermo Scientific, S. Series).

## Results and discussion

### X-ray diffraction

The XRD patterns of PLA and Ag/PLA-NCs are shown in Figure 1. In addition to the broad diffraction peak, which was centered at 16.25° and could be assigned to PLA, 5 crystalline peaks were observed at 2θ° of 38.18°, 44.3°, 64.55°, 77.54°, and 81.71°. Their intensities were found to be markedly enhanced with the increasing Ag-NP content in the polymeric matrix. In more specific, they were attributed to the 111, 200, 220, 311, and 222 crystallographic planes of face-centered cubic (fcc) silver crystals, respectively<sup>30</sup> (XRD ref no 01-087-0718). The XRD peaks broadenings of Ag-NPs (8, 16, and 32 wt% respectively) were mostly because of the existing nanosized particles in the nanocomposites.<sup>31</sup> Based on the information presented in Figure 1, five silver crystalline peak intensities were also found to increase with the increase in the percentage of Ag-NPs in PLA. This implies that the Ag-NPs existed in the surface and inside of PLA sheets.

**Figure 1** X-ray diffraction patterns of PLA (A), 8 (B), 16 (C), 32 (D) wt% of Ag/PLA-NCs.

**Abbreviations:** PLA, poly (lactic acid); NC, nanocomposite.

### UV-visible spectroscopy

After adding reducing agent, the color of the solution turned light brown, brown, and dark brown. The generation of Ag-NPs could be identified from the UV-vis spectra. The characteristic of the silver SPR bands was detected to be around 400 nm. These absorption bands were presumably corresponding to the Ag-NPs smaller than 10 nm.<sup>32,33</sup> Nonetheless, there is no characteristic UV-vis absorption of Ag-NPs before adding NaBH<sub>4</sub> into AgNO<sub>3</sub>/PLA (Figure 2a),

**Figure 2** UV-visible spectra of PLA (A), 8 (B), 16 (C), 32 (D) wt% of Ag/PLA-NCs.

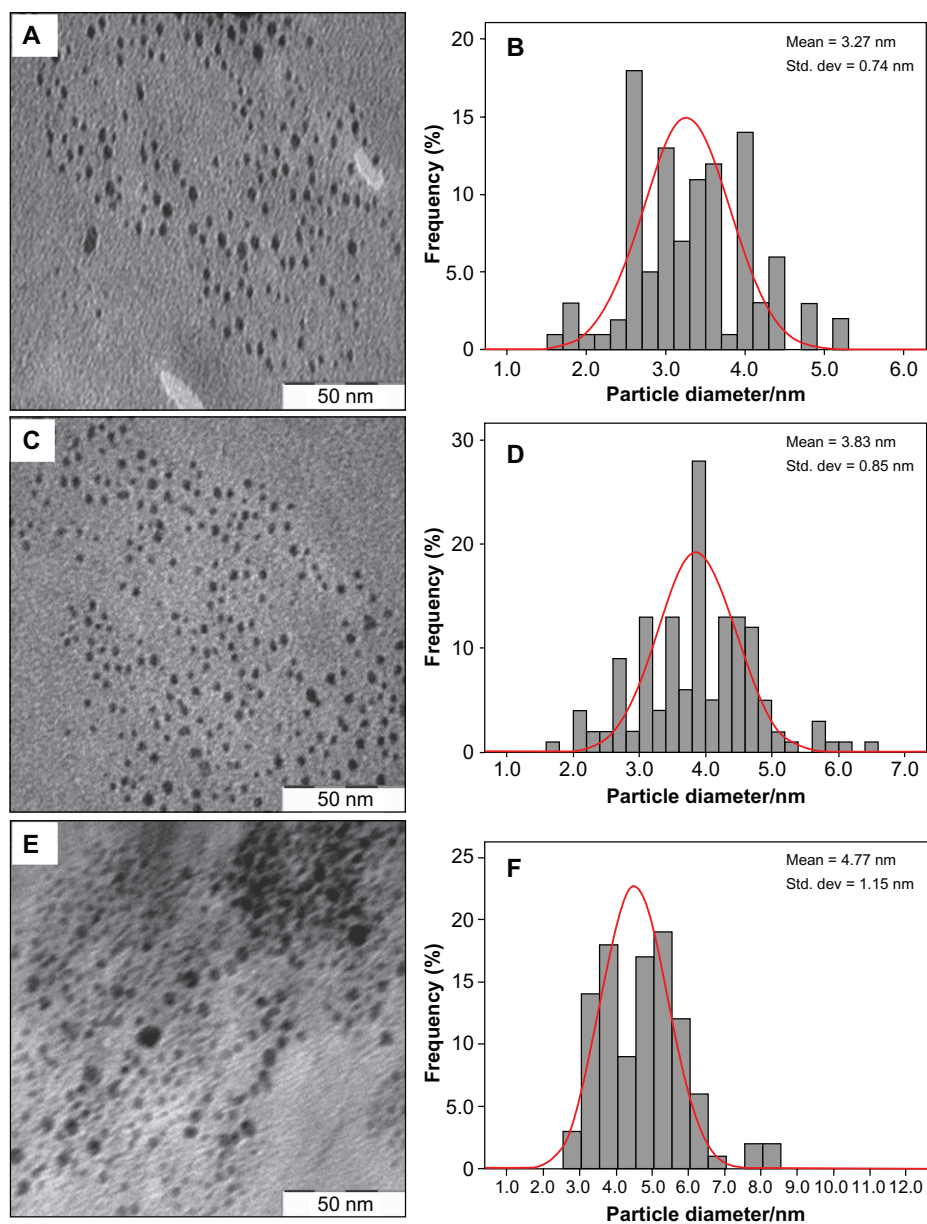

**Abbreviations:** PLA, poly (lactic acid); NC, nanocomposite.

while the growth of the Plasmon peak at 433 nm indicates the formation of Ag-NPs (Figure 2a). With the increase in Ag-NP concentration, the corresponding peak intensities in a range of wavelengths from 424–433 nm increases. The absorption peaks for the 16 and 32 wt% of Ag-NPs (Figures 2c and 2d) are slightly shifted to the lower wavelength (424 nm) indicating that mean diameters of Ag-NPs are different.<sup>21,34</sup>

## Morphology

Figure 3 demonstrates TEM and size distribution of Ag/PLA-NC film containing different amounts of Ag-NPs.

TEM image and their size distribution show that the mean diameters and standard deviation of Ag-NPs (8, 16, and 32 wt% relative to PLA) are  $3.27 \pm 0.74$ ,  $3.83 \pm 0.85$ , and  $4.77 \pm 1.15$  nm respectively. Furthermore, this confirms the uniform distribution of the Ag-NPs in the PLA matrix, although particles seem to aggregate to some extent. The observation could be attributed to a strong interaction between  $\text{AgNO}_3$  and PLA molecular chains, which promoted phase separation of polymer, thus preventing Ag-NPs from coagulating in the reduction process. TEM images show that with the increased percentages of Ag-NPs in the

**Figure 3** Transmission electron microscopy images and their corresponding size distributions of Ag/PLA-NCs at different Ag-NP percentages: 8 (A, B), 16 (C, D), and 32 wt% (E, F).

**Abbreviations:** PLA-NC, poly (lactic acid) nanocomposite; Ag-NP, silver nanoparticle.

polymeric matrix, particle diameters and standard deviation are increased.

## FT-IR chemical analysis

FT-IR spectroscopy was used to characterize the interaction between the Ag-NPs with PLA. Figure 4 shows FT-IR peaks for PLA and Ag/PLA-NCs (8, 16, and 32 wt% relative to PLA). The peaks at 1177 (1071), 2989 (2936), and 3502  $\text{cm}^{-1}$  were assigned to the C–O, C–H (double) and O–H stretching of the –CH(CH<sub>3</sub>)–OH end group of PLA, respectively. The splitting of the C=O carbonyl stretching at ca. 1744  $\text{cm}^{-1}$  might be due to the presence of –CH–CO–O– group. The peaks at 1448, and 1356  $\text{cm}^{-1}$  were assigned –CH<sub>3</sub>, and –CH– bending including symmetric and asymmetric bending.<sup>35,36</sup> The interactions between PLA chain molecules and Ag-NPs are associated with the peak at 3493  $\text{cm}^{-1}$ . Broad peak is due to the presence of van der Waals interactions between the hydroxyl groups of PLA and the partial positive charge on the surface of the Ag-NPs.<sup>37</sup>

## Silver ion release

Silver ions released from the Ag/PLA-NC films were investigated in PBS (pH = 7.00). The released silver was detected using the atomic absorption spectroscopy, and it should be silver cations Ag<sup>+</sup>. Therefore, the metallic silver in the polymeric matrix was converted to cationic silver during the release process through reaction with water. As shown

in Figure 5, the release of Ag<sup>+</sup> for a given silver content is relatively fast at the beginning, but it becomes slower according to incubation time, and the release can last for more than 18 days. The accumulative amount of silver ions released is dependent on the silver content in the polymeric films, whereby more initial silver content leads to a much faster release of Ag<sup>+</sup>. A steady and prolonged release of silver cations can inhibit the growth of bacteria when their concentrations are above 0.1 ppb. In the present study, the accumulative amount of the silver ions released could reach up to 60 ppm of the polymeric films at the beginning stage of release. This suggests that Ag/PLA-NC films may have antibacterial ability.

## Antibacterial results

Based on the results gathered from the agar disc diffusion test, all the Ag/PLA-NC films were found to exhibit a significant inhibition activity against *E. coli* ATCC 13706, *S. aureus* ATCC 12600, and *V. parahaemolyticus* ATCC 17802. The clear zones of the samples are shown in Table 1. Meanwhile, the inhibition zones surrounding the film square were formed, and these ranged from 1.43 to 10.33 mm against *E. coli*, from 4 to 15 mm against *V. parahaemolyticus*, and from 4 to 9.3 mm against *S. aureus*, respectively, suggesting an antimicrobial activity of Ag/PLA-NCs. It is important to note that the antibacterial efficacies against Ag/PLA-NC films indicate that Ag-NPs are responsible for the antibacterial activity in

**Figure 4** Fourier transform infrared spectra of PLA (A), Ag/PLA-NCs at 8 (B), 16 (C), 32 (D) wt% Ag-NPs. **Abbreviations:** PLA, poly (lactic acid); NC, nanocomposite; Ag-NP, silver nanoparticle.

**Figure 5** Ag<sup>+</sup> release curves of Ag/PLA-NCs in PBS (pH = 7.00) with 8, 16, and 32 wt% respectively.

**Abbreviations:** PLA, poly (lactic acid); NC, nanocomposite; PBS, phosphate buffer saline.

the polymer nanocomposites, and this activity is completely strong. The Ag-NPs are gradually released to Ag<sup>+</sup>, and thus, the antibacterial activity becomes tough. Similarly, the antibacterial efficacy against *V. parahaemolyticus* is more than the one against *E. coli*, and this is probably because of the difference in cell walls between the Gram-negative bacteria. These different behaviors are shown between *S. aureus* (as Gram-positive bacteria) and *E. coli* (as Gram-negative bacteria). The cell wall of *E. coli*, containing lipids, proteins, and lipopoly-saccharides (LPS) provides an effective protection against biocides. However, the cell wall of the Gram-positive bacteria, such as *S. aureus*, does not contain LPS.<sup>38</sup> Figure 6 shows typical results of the tests carried out for the purpose of a first qualitative evaluation for *V. parahaemolyticus*; the antibacterial activity is evidenced by a zone of bacteria-growth inhibition, for the PLA and Ag/PLA-NC (8, 16, and 32 wt%) films. A similar inhibition zone is not present around the PLA film in Figure 6a, and there is bacteria growth also on the top of the sample. As expected, the most notable antibacterial

**Table 1** Average of inhibition zones for PLA and Ag/PLA-NCs content 8, 16, and 32 wt%

Bacteria Film samples	Inhibition zone (mm)		
	<i>Escherichia coli</i>	<i>Staphylococcus aureus</i>	<i>Vibrio parahaemolyticus</i>
Control	–	0.67	–
Ag/PLA 8 wt%	1.43	4.00	4.00
Ag/PLA 16 wt%	2.33	8.00	8.00
Ag/PLA 32 wt%	10.33	9.33	15.00

**Abbreviations:** PLA, poly (lactic acid); NC, nanocomposite.

**Figure 6** Comparison of inhibition zone test for *Vibrio parahaemolyticus* between PLA (A), Ag/PLA-NC content 8 (B), 16 (C), and 32 (D) wt% respectively.

**Abbreviations:** PLA, poly (lactic acid); NC, nanocomposite.

effect is observed for the Ag/PLA-NCs (32 wt%) with the highest percentage (Figure 6d); reduced antibacterial effect are noted in Figures 6b and 6c respectively.

## Conclusion

A simple way to prepare uniform size of Ag-NPs in PLA by reacting different percentages of nanoparticles in PLA with sodium borohydride as reducing agent was developed. The average diameters of the Ag-NPs were between 3.27, 3.83, and 4.77 nm with well crystallized structures, and Ag-NP diameters increase with increasing amount of AgNO<sub>3</sub> added. XRD analysis confirms that crystallographic planes of the silver crystal are the fcc types. UV-vis absorption spectra show peaks characteristic of the surface plasmon resonance of Ag-NPs. FT-IR shows that interactions exist between molecules of PLA and Ag-NPs. The antibacterial activity of Ag/PLA-NC films was demonstrated and showed a strong antibacterial activity against Gram-negative and Gram-positive bacteria. Further studies investigate the bactericidal effect of Ag/PLA-NC films on the types of bacteria for potentially widening such wound dressings or as anti-adhesion membranes.

## Acknowledgments

Thanks are due to Professor Abdolhossein Rustaiyan and Mrs Parvaneh Shabanzadeh for helpful discussions and in giving the authors the idea. The authors are also grateful to the Institute of Bioscience (IBS/UPM) and Mrs A Jusoh in the TEM unit for technical assistance in this project.
