Received 7 November 2009; accepted 16 November 2009

Key indicators: single-crystal X-ray study;  $T = 110$  K; mean  $\sigma(C-C) = 0.004$  Å; H-atom completeness 91%; disorder in main residue;  $R$  factor = 0.032;  $wR$  factor = 0.081; data-to-parameter ratio = 8.1.

The crystal structure of  $\beta$ -cyclodextrin,  $C_{42}H_{70}O_{35}\cdot10.41H_2O$ , consists of truncated cone-shaped  $\beta$ -cyclodextrin molecules that are herringbone packed. The primary hydroxy groups form an intramolecular hydrogen-bonded array. The semi-polar cavity of the cyclodextrin host is filled with water molecules, which show partial occupancy and disorder.

## $\beta$ -Cyclodextrin 10.41-hydrate

R. W. Seidel and B. B. Koleva

### Comment

Cyclodextrins are common, widely studied and cheaply available supramolecular hosts (Atwood *et al.*, 1996; Szejtli, 1998) with a variety of applications in the food, cosmetics and pharmaceutical industries (Del Valle, 2004).

$\beta$ -Cyclodextrin ( $\beta$ -CD) is a cyclic oligosaccharide comprising seven *D*-glucopyranoside units, linked through 1,4-glycosidic bonds. The first room temperature crystal structure determination of  $\beta$ -CD dodecahydrate was reported about 40 years ago (Hamilton *et al.*, 1968). A number of room temperature determinations have been reported since (Szejtli & Budai, 1977; Lindner & Saenger, 1978; Lindner & Saenger, 1982; Fujiwara *et al.*, 1983; Betzel *et al.*, 1984; Steiner & Koellner, 1994; Damodharan *et al.*, 2004). A search of the Cambridge Structural Database (CSD; Version 5.3 with September 2009 Updates) (Allen *et al.*, 2002) revealed no low temperature X-ray structure determination of a  $\beta$ -CD hydrate with the exception of those reported by Stezowski & MacLennan (1980) and Kurokawa *et al.* (2004). Those were apparently reported without atomic coordinates and with an *R* factor of 13.0% and without refinement details, respectively. Additionally, a neutron diffraction study of deutero- $\beta$ -CD 11  $D_2O$  at 120 K was reported by Zabel *et al.* (1986); the refinement of which converged at *R* = 0.049. Herein, we report an X-ray structural study of  $\beta$ -CD 10.41 hydrate at 110 K with *R* = 0.032 in order to provide an improved model of the  $\beta$ -CD host, (I).

Figs 1 and 2 show a displacement ellipsoid plot and an illustration of the molecular structure of the  $\beta$ -CD host, respectively. The shape of the molecule is a truncated cone. The geometric parameters lie within expected ranges. All *D*-glucopyranoside units exhibit the C1 chair conformation. The primary hydroxy groups at the wider end of the torus form an array of intramolecular H bonds with O—H···O contacts in the range of 2.776 (2)–3.065 (3) Å. The estimated volume of the semi-polar cavity of a  $\beta$ -CD host is 262 Å<sup>3</sup> (Szejtli, 1998). In (I), the cavity was found to be statistically occupied by approximately 5.41 water molecules. Three of the water positions are each disordered over two positions, while five are considered to be partially occupied (see Refinement). In the vast number of structural studies dealing with  $\beta$ -CD hydrates, different solvent water contents were encountered. The solvent water content depends on the crystallization conditions and the humidity (Steiner & Koellner, 1994). In the crystal structure of (I), the  $\beta$ -CD molecules are arranged in herringbone-packed layers that are stacked along the *c* axis direction (Fig. 3).

### Experimental

Crystals of (I) were obtained unintentionally from an aqueous solution of  $\beta$ -cyclodextrin during an attempt to prepare an inclusion compound with an organic dye. A heterogeneous solid of (I) and the dye was obtained instead of the desired inclusion compound when the solvent was allowed to evaporate slowly. The solid was filtered off and dried over P<sub>4</sub>O<sub>10</sub>. A colourless crystal of (I) could be separated for the X-ray analysis.

---

### Refinement

In the absence of significant anomalous scattering effects, 5934 Friedel pairs were merged. Anisotropic displacement parameters were introduced for all non-hydrogen atoms with the exception of O47, O48, O49, O50 and O51, the positions of which are not fully occupied. One of the secondary hydroxy groups of the  $\beta$ -cyclodextrin host was found to be disordered over two positions. The ratio of occupancies of O5 and O5' was refined by means of a free variable and converged at 0.917 (5):0.083 (5). Standard similarity restraints on geometry and displacement parameters as well as rigid bond restraints were applied to the disordered group. The O44, O45 and O46 atoms of the solvent water molecules were each found to be disordered over two positions. The refinement of the occupancies by means of a free variable in each case yielded: 0.903 (5):0.097 (5), 0.803 (6):0.197 (6) and 0.884 (9):0.116 (9) for O44, O45 and O46, respectively. The parts of disordered water oxygen atoms were each refined with equivalent anisotropic displacement parameters. The site occupancy factors of O47, O48, O49, O50 and O51 were allowed to refine freely to yield 0.167 (9), 0.081 (8), 0.061 (8), 0.060 (8) and 0.039 (8), respectively. Four of the calculated intermolecular O···O distances (O43···O50 *ca* 2.01 Å, O44···O49 *ca* 1.73 Å, O45···O47 *ca* 2.29 Å and O46···O51 *ca* 2.42) indicate that the two positions cannot be occupied simultaneously in each case. The C-bound H atoms were placed at geometrically calculated positions (C—H = 0.99–1.00 Å) and refined with a riding model and with  $U_{\text{iso}}(\text{H}) = 1.2 U_{\text{eq}}(\text{C})$ . The hydroxy- and water-H atoms were localized in difference Fourier syntheses. The hydroxy-H atoms were subsequently refined with O—H = 0.84 Å and constrained tetrahedral C—O—H angles. The O—H bond lengths of the water molecules were restrained to a target value of 0.84 (2) Å. The 1,3-H,H distances of the water molecules were restrained to be similar with an effective standard deviation of 0.04 Å. The hydroxy- and water-H atoms were refined with  $U_{\text{iso}}(\text{H}) = 1.2 U_{\text{eq}}(\text{O})$ . The positions for some of the H atoms in some of the water molecules could not be determined reliably and were therefore excluded from the refinement.

### Figures

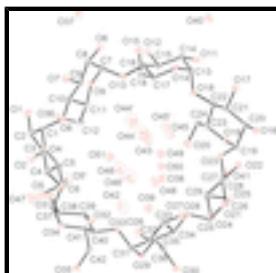

Fig. 1. The asymmetric unit of (I), with displacement ellipsoids drawn at the 50% probability level. Positions of disordered O atoms with minor occupancy and those not fully occupied are drawn as empty ellipsoids. Hydrogen atoms are omitted for clarity.

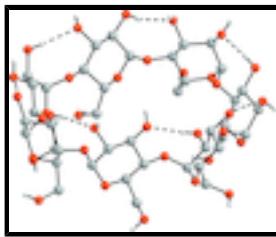

Fig. 2. Molecular Structure of the  $\beta$ -cyclodextrin host in (I). H bonds are represented by dashed lines. H atoms attached to carbon are omitted for clarity.

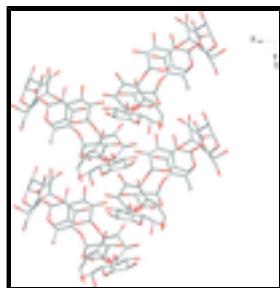

Fig. 3. View of the crystal structure of (I) viewed down the *c* axis, showing the herringbone packing of the  $\beta$ -cyclodextrin molecules. H atoms and water molecules are omitted for clarity.

## Special details

**Geometry.** All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating  $R$ -factors(gt) etc. and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on ALL data will be even larger.
