Received 29 January 2010; accepted 9 February 2010

Key indicators: single-crystal X-ray study; $T = 100\text{ K}$; mean $\sigma(\text{C}-\text{C}) = 0.004\text{ \AA}$; R factor = 0.065; wR factor = 0.181; data-to-parameter ratio = 11.4.

The title compound, $C_{21}H_{21}N_3O_2$, was obtained following a five-step synthetic procedure yielding weakly diffracting rod and needle-shaped crystals which crystallized concomitantly. Structural analysis of a rod-shaped crystal showed that the central seven-membered heterocyclic ring adopts a conformation that is perhaps best described as a distorted boat, with the H-bearing (CH_2 and NH) atoms lying well out of the least-squares mean plane fitted through the other five atoms in the ring (r.m.s. deviation 0.075 \AA). In the crystal, the compound packs as a twisted chain, which propagates along the b axis by means of an $R_2^1(6)$ motif formed by one of the carbonyl O atoms acting as a bifurcated acceptor in an $\text{N}-\text{H}\cdots\text{O}$ and $\text{C}-\text{H}\cdots\text{O}$ interaction. No diffraction was observed from the needle-shaped crystals.

2-Butyl-11-phenyl-5,10-dihydro-1*H*-benzo[*e*]imidazo[1,5-*a*][1,4]diazepine-1,3(2*H*)-dione

G. S. Nichol, S. Gunawan, J. Dietrich and C. Hulme

Comment

We recently investigated a three step solution phase protocol for the synthesis of arrays of tricyclic fused hydantoin-benzodiazepines as part of broader research on multi-component reactions (Figure 1). Interestingly, the major product of this unique synthetic route was the tautomer **5** derived from the originally desired product **4**, the structure being confirmed by X-ray crystallography. The methodology employs *ortho*-N-Boc benzylamines **1** and phenylglyoxaldehydes **2** in the rarely used five component Ugi reaction with CO₂ to assemble desired diversity in product **3** (Hulme *et al.*, 2000). Acid treatment unmasks an internal amino nucleophile and promotes rapid formation of the diazepine ring of generic structure **4**. Subsequent base treatment employs the amide NH of the Ugi scaffold as a second internal nucleophile promoting hydantoin formation and an unexpected 1,3-H shift to give **5**. As such the methodology represents an example of a post-condensation Ugi modification (Hulme & Gore, 2003) that employs two internal nucleophiles in distinct operations, generating a novel scaffold of high complexity in three succinct functional operations.

Two types of crystals were formed: very fine yellow needles together with a few slightly larger rod-shaped pale yellow crystals. The needles did not give any measurable diffraction and the rod crystals showed weak diffraction with 60 second exposure times; a resolution cutoff of 0.87 Å was applied to the dataset. The identity of the needle crystals was not established. The molecular structure of **5** is shown in Figure 2. Molecular dimensions are unexceptional. The amine hydrogen atom was located in a difference Fourier map and its presence is confirmed by participation in hydrogen bonding discussed below. The central 7-membered heterocyclic ring adopts a conformation that is perhaps best described as a distorted boat with the H-bearing (C3 and N3) atoms lying well out of a least squares mean plane fitted through the other five atoms in the ring [r.m.s. deviation 0.075 Å; C3 deviates by 0.679 (5) Å and N3 deviates by 0.301 (4) Å]. The compound packs as a twisted chain which propagates along the *b* axis by means of an *R*¹2(6) motif (Bernstein *et al.*, 1995) formed by one of the carbonyl oxygen atoms acting as bifurcated acceptor in an N–H···O and C–H···O interaction (Figure 3).

Experimental

Ugi reaction (For R₁, R₂=H, R₃=n-butyl)

CO₂ gas was bubbled through a stirring solution of MeOH for 25 minutes to generate methyl carbonic acid. In a separate 25 ml flask, phenyl glyoxal **2** (226 mg, 1.687 mmol) was added to BOC-2-aminobenzylamine **1** (250 mg, 1.125 mmol). Methyl carbonic acid (10 ml) and *N*-butyl isonitrile (0.237 ml, 2.252 mmol) were then added to the latter flask. The reaction was stirred at room temperature under an atmosphere of CO₂ for 16 h. The solvent was evaporated *in vacuo* and the crude product purified with a Biotage Isolera4TM system (hexane/EtOAc 10-30%) to afford the Ugi product **3** (218 mg, 0.438 mmol, 39%) as a yellow oil.

De-BOC and Cyclization

supplementary materials

3 (0.180 g, 0.362 mmol) was treated with a 5 ml 10% TFA solution in 1,2-dichloroethane which was irradiated in a Biotage InitiatorTM at 80°C for 20 min. The resulting orange solution was washed with 1M NaHCO₃ (4 × 2.5 ml) and the organic layer dried (Na₂SO₄), filtered and evaporated *in vacuo*. MeOH (1.5 ml), THF (0.75 ml), H₂O (0.5 ml) were added to the crude product **4** (0.102 g, 0.269 mmol) followed by a 1 g/1 ml solution of KOH in H₂O (0.03 ml). The solution was irradiated at 100°C for 20 min and resultant orange solution partitioned between EtOAc (5 ml) and 1M NaHCO₃ (5 ml). The organic layer was dried (Na₂SO₄), filtered and evaporated *in vacuo*. Final crude product was purified with a Biotage Isolera⁴TM (hexane/EtOAc 30%) to afford the final product **5** (0.074 g, 0.214 mmol, 80%) as a yellow solid. FT-ICR calculated for C₂₁H₂₂N₃O₂ [M+H]⁺: 348.1707, found: 348.1707.

Refinement

A resolution cutoff of 0.87 Å was applied to the dataset due to unobserved diffraction beyond this point. Nevertheless the N—H hydrogen atom was located in a difference Fourier map and the N—H distance freely refined to 0.86 (4) Å with U_{iso}(H) = 1.2 U_{eq}(N). C—H atoms were refined with U_{iso}(H) = 1.5 U_{eq}(C) (methyl) or U_{iso}(H) = 1.2 U_{eq}(C) (all others) with constrained C—H distances in the range 0.95–0.99 Å. The largest residual peak, 0.7 e.Å⁻³, is approximately 1.53 Å from C21.
