Summary

The protozoan parasite *Cryptosporidium parvum* is a major cause of gastrointestinal disease; no effective drug therapy exists to treat this infection. Curiously, *C. parvum* IMPDH (*Cp*IMPDH) is most closely related to prokaryotic IMPDHs, suggesting that the parasite obtained its *IMPDH* gene via horizontal transfer. We previously identified inhibitors of *Cp*IMPDH that do not inhibit human IMPDHs. Here we show that these compounds also inhibit IMPDHs from *Helicobacter pylori*, *Borrelia burgdorferi*, and *Streptococcus pyogenes*, but not from *Escherichia coli*. Residues Ala165 and Tyr358 comprise a structural motif that defines susceptible enzymes. Importantly, a second generation *Cp*IMPDH inhibitor has bacteriocidal activity on *H. pylori* but not *Escherichia coli*. We propose that *Cp*IMPDH-targeted inhibitors can be developed into a new class of antibiotics that will spare some commensal bacteria.

Introduction

Microbial infections are now the second leading cause of death worldwide. Many commonly used antibiotics have been rendered ineffective by the upsurge of drug resistance, and years of neglect have left a mere trickle of new antibiotics in the pipeline, creating an urgent need for novel scaffolds and targets (Fischbach and Walsh, 2009). The re-purposing of other drug development programs for antibiotic discovery is a promising strategy to address this problem (Miller, et al., 2009; Walsh and Fischbach, 2009). Inosine 5'-monophosphate dehydrogenase (IMPDH) presents an intriguing opportunity for such re-purposing. This enzyme catalyzes the pivotal step in guanine nucleotide biosynthesis, the conversion of IMP to XMP with the concomitant reduction of NAD⁺ in a reaction that involves a covalent intermediate E-XMP* (Figure 1a). The guanine nucleotide pool controls proliferation, so IMPDH inhibitors such as mycophenolic acid, merimepodib, mizoribine, tiazofurin and ribavirin are used in immunosuppressive, cancer and antiviral therapy. As yet IMPDH inhibitors have not been exploited in antimicrobial applications, in part because no bacterial-selective IMPDH inhibitors have been identified (Hedstrom, 2009).

The development of IMPDH-based therapy is further complicated by the conformational gymnastics of the catalytic cycle (Hedstrom, 2009). IMPDHs have two conformational states, an open conformation that allows NAD to bind, and a closed conformation where a mobile flap binds in the NAD site (Figure 1b; (Hedstrom, 2009)). The closed conformation is required for the hydrolysis of the covalent intermediate E-XMP*. Thus the flap competes with inhibitors that bind in the NAD site, and this competition is an important determinant of inhibitor potency (Hedstrom, 2009). For example, *Trichostrongylus axei* IMPDH is 400-fold more resistant to mycophenolic acid than human IMPDH2; ~10-fold of this difference is due to changes in the structure of the inhibitor binding site while ~40-fold can be attributed to a preference for the closed conformation (Dignard and Hedstrom, 2000). Therefore, for *Tj*IMPDH, the conformational equilibrium is a more important determinant of inhibitor susceptibility than the residues that contact the inhibitor. This example illustrates the difficulty in predicting inhibitor action from IMPDH sequence.

The protozoan parasite *Cryptosporidium parvum* is a major cause of diarrhea and malnutrition and a potential bioterrorism agent (Fayer, 2004). The parasite has a streamlined purine salvage pathway that depends on IMPDH for the production of guanine nucleotides (Abrahamsen, et al., 2004; Striepen, et al., 2004). Surprisingly, *Cp*IMPDH is closely related to prokaryotic IMPDHs (e.g., *Helicobacter pylori* IMPDH, Figure 1c), suggesting that its *IMPDH* gene was obtained by horizontal transfer (Striepen, et al., 2004; Striepen, et al., 2002)). Prokaryotic and eukaryotic IMPDHs differ in both structural features and kinetic properties (Zhang, et al., 1999), which suggests that selective inhibition should be possible. We have recently identified eight selective inhibitors of *Cp*IMPDH in a high throughput screen targeting the NAD site (compounds **A–H**, Table 1) (Kirubakaran, et al.; MacPherson, et al.; Maurya, et al., 2009; Umejiego, et al., 2008). Several of these inhibitors display antiparasitic activity in a tissue culture model of *C. parvum* infection (Umejiego, et al., 2008). A program of medicinal chemistry optimization has yielded inhibitors with nanomolar affinity in several structurally distinct frameworks (Kirubakaran, et al.; MacPherson, et al.; Maurya, et al., 2009).

Mycophenolic acid and merimepodib bind in the nicotinamide subsite of the NAD site of human IMPDH, stacking against the purine ring of E-XMP* and within a single subunit of the tetramer (Sintchak, et al., 1996; Sintchak and Nimmesgern, 2000). In contrast, the x-ray crystal structure of inhibitor **C64** revealed that this inhibitor interacts with the purine ring of IMP and then crosses the dimer interface to interact with Tyr358 in the adjacent subunit (Figure 2a,b; *Cp*IMPDH numbering; (MacPherson, et al.)). At present, no structures are available of the other inhibitor complexes. However, with the exception of compound **E**, all of the inhibitors contain two aromatic groups linked by spacers of similar length (Table 1), and therefore may be able to recapitulate this binding mode.

Here we demonstrate that Tyr358 together with Ala165 comprise a structural motif that defines susceptibility to all eight *Cp*IMPDH inhibitors. This motif is found in a wide variety of pathogenic bacteria. Importantly, the *Cp*IMPDH inhibitor **C91** blocks *H. pylori* growth, but not the growth of *Escherichia coli*. These observations suggest that *Cp*IMPDH-targeted inhibitors can be developed into a new class of broader spectrum antibiotics that will spare commensal bacteria.

Results and Discussion

Expression, purification and characterization of recombinant IMPDHs

We expressed and purified prokaryotic IMPDHs from representative organisms: *H. pylori* (Gram negative ϵ proteobacteria), *E. coli* (Gram-negative γ proteobacteria), *B. burgdorferi* (spirochete), *S. pyogenes* (Gram-positive) and the protozoan parasite *T. foetus*, which also

appears to have obtained its *IMPDH* gene from a prokaryote (Baptiste and Philippe, 2002). We also expressed an additional eukaryotic IMPDH from the protozoan parasite *Leishmania donovani*. *EcIMPDH*, *BbIMPDH*, *TfIMPDH*, *SpIMPDH* and *LdIMPDH* have been characterized previously (Digits and Hedstrom, 1999; Dobie, et al., 2007; Kerr and Hedstrom, 1997; Zhang, et al., 1999; Zhou, et al., 1997). The kinetic parameters of *HpIMPDH* are very similar to those of *CpIMPDH*, and are generally characteristic of bacterial IMPDHs (Table S2; (Hedstrom, 2009; Umejiego, et al., 2004; Zhang, et al., 1999)). Importantly, structures are available for *TfIMPDH*, *SpIMPDH* and *BbIMPDH* as well as for *CpIMPDH* and the human enzymes (Colby, et al., 1999; Gan, et al., 2002; Gan, et al., 2003; MacPherson, et al.; McMillan, et al., 2000; Prorise and Luecke, 2003; Prorise, et al., 2002; Sintchak, et al., 1996; Whitby, et al., 1997; Zhang, et al., 1999). *CpIMPDH* is most closely related to *HpIMPDH* with 60% sequence identity (Figure 1c; Table S1). The sequence of *CpIMPDH* is ~50% identical to *EcIMPDH*, *BbIMPDH* and *SpIMPDH* and ~30% identical to *TfIMPDH* and the eukaryotic enzymes (Table S1)(Min, et al., 2008; Striepen, et al., 2002). Importantly, *HpIMPDH*, *BbIMPDH* and *SpIMPDH* contain Tyr358 and are therefore expected to be susceptible to the C series inhibitors and perhaps also to the other *CpIMPDH* inhibitors.

Spectrum of inhibition of C series inhibitors

Compound C inhibits *HpIMPDH* and *BbIMPDH* with similar values of IC_{50} to *CpIMPDH* (Table 1). C is a noncompetitive (mixed) inhibitor of *HpIMPDH* with respect to NAD^+ (data not shown), as observed with *CpIMPDH* (Umejiego, et al., 2008). Importantly, the values of K_i and IC_{50} are similar, as expected for noncompetitive inhibition. C also inhibits *SpIMPDH*, although in this case the value of IC_{50} is increased by a factor of ~60 relative to *CpIMPDH*. No inhibition is observed at 100 μM C for *TfIMPDH*, *EcIMPDH* and *LdIMPDH*, as expected since these enzymes do not contain Tyr358.

We also evaluated the spectrum of a second generation inhibitor, **C91**, arising from our medicinal chemistry optimization program (Kirubakaran, et al.); this compound is a potent inhibitor of *CpIMPDH* with $IC_{50} = 8$ nM. **C91** is also a potent inhibitor of both *HpIMPDH* and *SpIMPDH*, demonstrating that potent broader spectrum inhibitors can be obtained (Table 1). **C91** fails to inhibit *EcIMPDH*, *TfIMPDH*, *LdIMPDH* or human IMPDHs ($IC_{50} > 10$ μM).

The conformational contribution to inhibitor selectivity

As noted in the introduction, IMPDH undergoes a conformational change in the middle of its catalytic cycle that brings a mobile flap into the NAD site (Figure 1b). The competition of the flap for this site can be an important determinant of inhibitor susceptibility, and might explain the low susceptibility of *SpIMPDH* to C despite the presence of Tyr358 (Table 2; (Guillén Schlippe and Hedstrom, 2005; Guillén Schlippe and Hedstrom, 2005; Guillén Schlippe, et al., 2004; Hedstrom, 2009; Kohler, et al., 2005; Riera, et al., 2008; Umejiego, et al., 2004)). Therefore we determined the equilibrium between open and closed conformations (K_c) for the various IMPDHs (Table 2 and Figure S3; see Supplemental Material for description (Hedstrom, 2009)). The values of K_c vary considerably among the prokaryotic IMPDHs, from 0.7 for *BbIMPDH* to 140 for *TfIMPDH*.

Tiazofurin inhibition illustrates the validity of this approach and the magnitude of the conformational contribution to inhibitor selectivity. The tiazofurin binding site is conserved among prokaryotic IMPDHs (Figure 2c), which predicts that *CpIMPDH*, *HpIMPDH*, *BbIMPDH*, *SpIMPDH*, *EcIMPDH* and *TfIMPDH* should all bind tiazofurin with similar affinity, yet the measured values of K_i vary from 1–69 mM. When the measured values of K_i are adjusted for competition from the mobile flap, that is, by dividing by a factor of $1 + K_c$

to normalize for the fraction of protein in the open conformation, the resulting “intrinsic” values are indeed nearly identical, ranging from 0.3–0.7 mM (Table 2). In contrast, the intrinsic values of K_i for ADP range from 0.2–9 mM, reflecting the structural divergence of the ADP binding sites among the six enzymes (Figure 2c). Therefore the intrinsic values reflect the structural similarity of the inhibitor binding sites.

The intrinsic values of IC_{50} for **C** are similar for *Cp*IMPDPH, *Hp*IMPDPH and *Bb*IMPDPH, indicating that the structures of inhibitor binding sites are also similar in these three enzymes. However, the intrinsic value of IC_{50} for **C** with *Sp*IMPDPH remains 40-fold greater than *Cp*IMPDPH. Figure 2 displays the conservation of the **C64** binding site among these IMPDPHs. While most of the residues within 5 Å of **C64** are conserved among these enzymes, Ser164 and Met326 are variable; these residues are Thr and Leu, respectively in *Sp*IMPDPH. Perhaps these substitutions account for the lower potency of **C** with *Sp*IMPDPH. In contrast, the intrinsic values of IC_{50} for **C91** are similar for *Cp*IMPDPH, *Hp*IMPDPH and *Sp*IMPDPH, indicating that the interactions that increase the potency of **C91** in *Cp*IMPDPH are also found in the other enzymes.

Structural determinants of **C** susceptibility

To determine if the presence of Tyr358 is sufficient to install sensitivity to inhibitor **C**, we replaced the corresponding residue in *Ec*IMPDPH with Tyr. The resulting variant, L444Y, has similar kinetic properties to *Ec*IMPDPH, except that the value of K_m for NAD^+ is increased by 5-fold (Table S2). Unlike *Ec*IMPDPH, **C** inhibits L444Y (Figure S2); however, L444Y is still ~100-fold less sensitive than *Cp*IMPDPH.

Inspection of the residues within 5 Å of **C64** revealed another potential structural determinant of **C** susceptibility: Ala165 (Figure 2a). The installation of Ala at the corresponding position of *Ec*IMPDPH also increased the sensitivity to **C**, although again the resulting variant, S250A, is ~100-fold less sensitive than *Cp*IMPDPH (Figure S2). However, the combination of these mutations created a variant S250A/L444Y with similar sensitivity to **C** as *Cp*IMPDPH (Table 1). The S250A/L444Y variant also displays similar sensitivity to **C91** (Table 1). Therefore Ala250 and Tyr358 comprise a minimal structural motif that defines sensitivity to **C**.

All of the *Cp*IMPDPH inhibitors interact with Ala165 and Tyr358

The spectra of inhibition of compounds **A**, **B** and **D–H** are also very similar to **C**. These seven compounds inhibit *Hp*IMPDPH, *Bb*IMPDPH and *Sp*IMPDPH, but not *Ec*IMPDPH, *Tj*IMPDPH or *Ld*IMPDPH (Table 1). These compounds are noncompetitive (mixed) inhibitors of *Hp*IMPDPH with respect to NAD^+ (data not shown), as observed with *Cp*IMPDPH (Umejiego, et al., 2008). Most importantly, the *Ec*IMPDPH variant S250A/L444Y is inhibited by **A**, **B** and **D–H**, indicating that together Ala165 and Tyr358 define the structural motif required for susceptibility to all the *Cp*IMPDPH inhibitors. Note that compound **E** has a single aromatic group, and therefore must interact exclusively with Tyr358 and not with the purine ring of IMP.

Two inhibitor binding modes exist

Although the above observations indicate that all of the compounds interact with Ala165 and Tyr358, inspection of the intrinsic values of IC_{50} for all of the *Cp*IMPDPH inhibitors reveals two distinct binding modes. The intrinsic values of IC_{50} of **C** range between 0.18–0.36 μ M for *Cp*IMPDPH, *Hp*IMPDPH, *Bb*IMPDPH and S250A/L444Y (Table 2), reflecting the conservation of this binding site (Figure 2d) (MacPherson, et al.). Likewise, the intrinsic affinities of compounds **A**, **B**, **D**, **E** and **F** are within a factor of 2 for all four enzymes, indicating that the binding sites of these compounds are also conserved. In contrast, the

intrinsic values of **A–F** for *Sp*IMPDH are very different from *Cp*IMPDH, indicating that this binding site is significantly different in *Sp*IMPDH (Table 1). Only one substitution is present within 3.5 Å of **C64**: Met326 is a Leu in *Sp*IMPDH. However, the Leu substitution is also present in *Hp*IMPDH and *Bb*IMPDH, and therefore cannot account for the different susceptibility. The next nearest substitution is Thr for Ser164; the side chain of Ser164 is 5 Å away from **C64**, but might be closer to **A**, **B** and **D–F**.

A different trend is observed in the intrinsic affinities of **G** and **H**. *Sp*IMPDH is most similar to *Cp*IMPDH, while *Hp*IMPDH and *Bb*IMPDH display lower affinities for these compounds (Table 2). These observations suggest that **G/H** bind in a region that is conserved in *Sp*IMPDH and *Cp*IMPDH, but different in the other enzymes. Therefore, at least a portion of the **G/H** binding site must be distinct from the site that binds **A–F**. Figure S3 reveals regions of conservation between *Cp*IMPDH and *Sp*IMPDH that are not shared with the other sensitive enzymes. These regions could serve as the binding site for **G/H**.

Inhibition of *H. pylori* growth

We chose to investigate the antibiotic potential of IMPDH inhibition in *H. pylori* because *Hp*IMPDH is most similar to *Cp*IMPDH. *H. pylori* causes gastrointestinal ulcers and stomach cancer; standard treatment involves triple therapy of a proton pump inhibitor, clarithromycin and amoxicillin or metronidazole (Selgrad and Malfertheiner, 2008). Moreover, resistance is developing to the standard triple therapy, and few new antibiotics are in the pipeline. *H. pylori* has complex growth requirements that necessitate the use of rich media containing xanthine and guanine (Brucella broth) (Tomb, et al., 1997). *H. pylori* will be resistant to IMPDH inhibitors if its salvage pathways can provide sufficient guanine nucleotides to support proliferation. Therefore this bacteria provides a demanding test for the antibiotic potential of IMPDH-targeted inhibitors

Figure 3 shows that 20 µM **C91** is sufficient to block the proliferation of a *H. pylori* culture exiting stationary phase. Higher concentrations of **C91** display bactericidal effects, with only 23% of the colony forming units remaining after 24 hr treatment with 200 µM. Exponentially growing *H. pylori* cells are also sensitive to **C91** (Figure S1); a concentration of 60 µM is sufficient to block growth while higher concentrations are bactericidal. Importantly, **C91** failed to inhibit the growth of *E. coli*, suggesting that the antibacterial effects of **C91** result from the inhibition of *Hp*IMPDH rather than an off-target effect.

Implications for the design of antibiotics targeting IMPDH

The above findings indicate that Ala165 and Tyr358 comprise a structural motif that defines enzymes susceptible to *Cp*IMPDH inhibitors. A BLAST search reveals that these critical residues are present in IMPDHs from a wide variety of pathogenic bacteria in addition to *C. parvum*, *B. burgdorferi*, *H. pylori* and *S. pyogenes*. Importantly, this list includes select agents and multi-drug resistant bacteria, where new antibiotics are urgently needed, but not *E. coli* (Table S1). As shown in Figure 2e, the inhibitor binding site is highly conserved among *C. parvum* and pathogenic bacteria, suggesting that IMPDH inhibition provides a promising strategy for the development of a broader spectrum antibiotic. Prokaryotic-specific inhibitors such as **C91** will be invaluable in validating IMPDH as a target for antibiotic chemotherapy that will spare commensal bacteria.

Significance

The rising tide of antibiotic resistance creates an urgent need for new drugs to treat bacterial infections, but years of neglect have depleted the antibiotic pipeline. The re-purposing of other drug development programs for antibiotic discovery is a promising strategy to address this problem. Inosine 5'-monophosphate dehydrogenase (IMPDH), a key enzyme in the

biosynthesis of the precursors for RNA and DNA, presents an intriguing opportunity for such re-purposing. IMPDH is a promising target for drugs against the protozoan parasite *CryptoSporidium parvum*, a major cause of diarrhea and malnutrition and a potential bioterrorism agent. Curiously, *Cp*IMPDH is most closely related to prokaryotic IMPDHs, suggesting that the parasite obtained its *IMPDH* gene via horizontal transfer. We previously identified inhibitors of *Cp*IMPDH that do not inhibit human IMPDHs. Here we show that selective inhibitors of *Cp*IMPDH also inhibit IMPDHs from the pathogenic bacteria *Helicobacter pylori*, *Borrelia burgdorferi*, and *Streptococcus pyogenes*, but not *Escherchia coli*. Importantly, a second generation *Cp*IMPDH inhibitor blocks *H. pylori* growth, demonstrating that these compounds have antibacterial activity. Susceptible enzymes are defined by a structural motif that is found in IMPDHs from a wide variety of pathogenic bacteria, suggesting that IMPDH-targeted inhibitors can be developed into a new class of broader spectrum antibiotics that will spare some commensal bacteria.

Experimental Procedures

Materials

Compounds **D**, **E**, **F**, **G**, and **H** were purchased from ChemDiv Inc. (San Diego, CA), Compounds **A**, **B** and **C** were synthesized as described previously (Umejiego, et al., 2008). Compound **C91** was synthesized as described in Supplementary Material. Full SAR of the **C** series will be described in (Kirubakaran, et al.). All other chemicals were obtained from Fisher Scientific, unless mentioned otherwise. Plasmid containing the *guaB* gene of *S. pyogenes* was a generous gift of Dr. Cameron Ashbaugh (Ashbaugh and Wessels, 1995). *H. pylori* total genomic DNA was obtained from American Type Culture Collection (ATCC). *L. donovani* IMPDH coding sequence was the gift of Dr. Buddy Ullman (Wilson, et al., 1991).

Enzyme Cloning and Purification

Recombinant *T. foetus*, *B. burgdorferi*, *E. coli* and *C. parvum* IMPDH were expressed in *guaB* strains of *E. coli* (which lack endogenous IMPDH) and purified as described previously (Digits and Hedstrom, 1999; Kerr and Hedstrom, 1997; Umejiego, et al., 2004; Zhou, et al., 1997). The S250A, L444Y and S250A/L444Y mutants of *E. coli* IMPDH were constructed using Quikchange (Stratagene, La Jolla, CA). Enzymes were expressed and purified as previously described (Kerr and Hedstrom, 1997).

To express *L. donovani* IMPDH, a *Nco*I site was created at the beginning of the *Ld*IMPDH coding sequence and the *Nco*I-PstI fragment was cloned into pKK233-2 to create the plasmid pLDI, which expresses *Ld*IMPDH under control of the *trc* promoter. Cultures were induced with 0.5 mM IPTG and grown overnight. Cells were harvested by centrifugation, resuspended in 50 mM Tris-HCl, pH 8.0, 1 mM dithiothreitol and 10 % glycerol (Buffer A), lysed by sonication and clarified by centrifugation followed by filtration through a 45 μ m cellulose acetate filter. Protein was applied to a Poros HS strong cation exchange resin (PerSeptive Biosystems) pre-equilibrated with 20 mM sodium phosphate buffer, pH 7.5, 1 mM dithiothreitol (Buffer B). *Ld*IMPDH was eluted with a gradient of 0–0.9 M NaCl. Fractions containing IMPDH activity were pooled and applied to IMP affinity resin. The column was washed with Buffer B and enzyme was eluted with Buffer B containing 0.5 M KCl, 1 mM IMP. The specific activity of the final preparation was 2.6 μ moles/min-mg.

The *H. pylori* and *S. pyogenes* *guaB* genes were cloned into pET28a with 6x His-tags. Bacteria were grown at 30°C in LB medium containing 25 μ g/mL kanamycin until the OD₆₀₀ reached approximately 0.6. Expression was initiated by the addition of 0.5 mM IPTG and the temperature was changed to 25°C. Bacteria were harvested after 16 hours. The cell

pellet was rinsed (3x) with 50 mM phosphate buffer, 500 mM NaCl, 5 mM imidazole, pH 8.0, 1 mM IMP and 5 mM β -mercaptoethanol, and lysed by sonication. The lysate was clarified by centrifugation and loaded on a Ni-NTA column (Qiagen). The purified protein were eluted in 50 mM phosphate buffer, 500 mM NaCl, 250 mM imidazole, pH 8.0, 1 mM IMP and 5 mM β -mercaptoethanol, concentrated and dialyzed against Buffer A. The protein concentration was determined by using Bradford dye procedure (BioRad).

Steady State Enzyme Kinetics

IMPDH assays were performed in 50 mM Tris-HCl, pH 8.0, 100 mM KCl, 3 mM EDTA and 1 mM DTT. Activity was routinely assayed in the presence of 50 nM IMPDH at 25 °C. NADH production was monitored either by following absorbance change at 340 nm using a Hitachi U-2000 spectrophotometer ($\epsilon = 6.2 \text{ mM}^{-1} \text{ cm}^{-1}$). IMPDHs are prone to NAD^+ substrate inhibition (Hedstrom, 2009). Therefore the steady state kinetics for *Hp*IMPDH were initially analyzed by varying NAD^+ at saturating IMP concentrations to determine the value of K_m for NAD^+ , then by varying IMP at the fixed NAD^+ concentration as close to saturating as practical. Using the SigmaPlot program (SPSS, Inc.), initial velocity data were fit to the Michaelis-Menten equation (Equation 1) and/or the uncompetitive substrate inhibition equation (Equation 2), as follows,

$$v = V_m[S]/(K_m + [S]) \quad (1)$$

$$v = V_m/(1 + K_m/[S] + [S]^2/K_{ii}) \quad (2)$$

where v represents the velocity, V_m is the maximal velocity, S is the substrate concentration, K_m is the Michaelis constant, K_{ii} is the intercept inhibition constant. The values of k_{cat} determined under both conditions are in good agreement.

Inhibitor Kinetics

Enzyme was incubated with inhibitor (50 pM – 100 μM) for 10 min at room temperature prior to addition of substrates. The conditions used for each enzyme is listed in Supplemental Material. IC_{50} values were calculated for each inhibitor according to Equation 3 using the SigmaPlot program (SPSS, Inc.):

$$v_i = v_0/(1 + [I]/\text{IC}_{50}) \quad (3)$$

where v_i is initial velocity in the presence of inhibitor (I) and v_0 is the initial velocity in the absence of inhibitor.

Assays were carried out in assay buffer at 25 °C with ~50 nM IMPDH and NADH production was monitored by following fluorescence. The values of K_i with respect to NAD^+ were determined by using fixed concentrations of IMP and varied NAD^+ concentrations. Data were fitted according to Equation 4 (noncompetitive inhibition) using SigmaPlot program (SPSS, Inc.):

$$v = V_m[S]/\{K_m(1 + [I]/K_{is}) + [S](1 + [I]/K_{ii})\} \quad (4)$$

where K_{ii} and K_{is} represent the intercept and slope inhibition constants, respectively. The best fits were determined by the relative fit error. The Morrison equation was used to evaluate tight-binding inhibitors (Morrison, 1969).

Determination of K_c

The values of K_c were determined by measuring the interaction between tiazofurin and ADP (Digits and Hedstrom, 2000; Hedstrom and Wang, 1990). Tiazofurin binds in the nicotinamide subsite of the NAD site while ADP binds in the adenosine subsite. If the closed conformation is favored, tiazofurin and ADP will interact synergistically—one inhibitor shifts the enzyme into the open conformation and promotes the association of the second inhibitor (Guillén Schlippe, et al., 2004). If the open conformation is favored, the two inhibitors bind independently. Tiazofurin and ADP concentrations are varied at constant IMP and NAD^+ . Initial velocities were fit to equation 5 using SigmaPlot:

$$v = v_0 / [1 + [I]/K_i + [J]/K_j + [I][J]/\alpha K_i K_j] \quad (5)$$

where v is the initial velocity, v_0 is the initial velocity in the absence of inhibitor, K_i and K_j are the inhibition constants for the inhibitors I and J, respectively and α is the interaction constant. The value of α approximates the fraction of enzyme in the open conformation, so the value of K_c is obtained (Guillén Schlippe, et al., 2004):

$$K_c = (1 - \alpha) / \alpha \quad (6)$$

Bacterial growth assays

H. pylori strain G27 (Baltrus, et al., 2009) was stored at -80°C in Brucella broth (Becton, Dickinson) supplemented with 10% fetal bovine serum (FBS) and 20% glycerol. Bacteria were plated on TSA/sheep blood agar plates (Remel) or grown in growth media (Brucella broth supplemented with 10% FBS and $4\mu\text{g/mL}$ fungizone/amphotericin B) at 37°C in a 10% CO_2 incubator. For growth inhibition assays, a frozen stock of *H. pylori* strain G27 was plated on blood agar plates and allowed to grow for 48 hours. The bacteria were re-suspended in growth media (30 ml) and incubated for ~ 18 –20 hours. The resulting stationary phase bacteria were diluted into assay media (Brucella broth with 10% FBS) to an $\text{OD}_{600} = 0.025$ ($\sim 10^4$ colony forming units/ μl) and aliquots (200 μl) were added to 96 well tissue-culture grade polystyrene plates (Costar, Corning Inc.). A DMSO solution of **C91** (2 μl) was added to each well and the plates were incubated with shaking. Colony forming units (CFUs) were measured by diluting aliquots at 0, 2, 4, 8, 12, and 24 hours, and plating on blood agar plates. Alternatively, logarithmic phase bacteria were obtained by diluting stationary phase bacteria 5x into fresh growth media (25 ml) and incubating with shaking for 4 hours prior to the growth inhibition assay.

An exponentially growing culture of *E. coli* MG1655 was diluted into fresh Luria broth containing C91 (100 and 200 μM) or DMSO. The triplicate cultures were incubated at 37°C in a plate reader and optical density was recorded every minute over 3.5 hours.

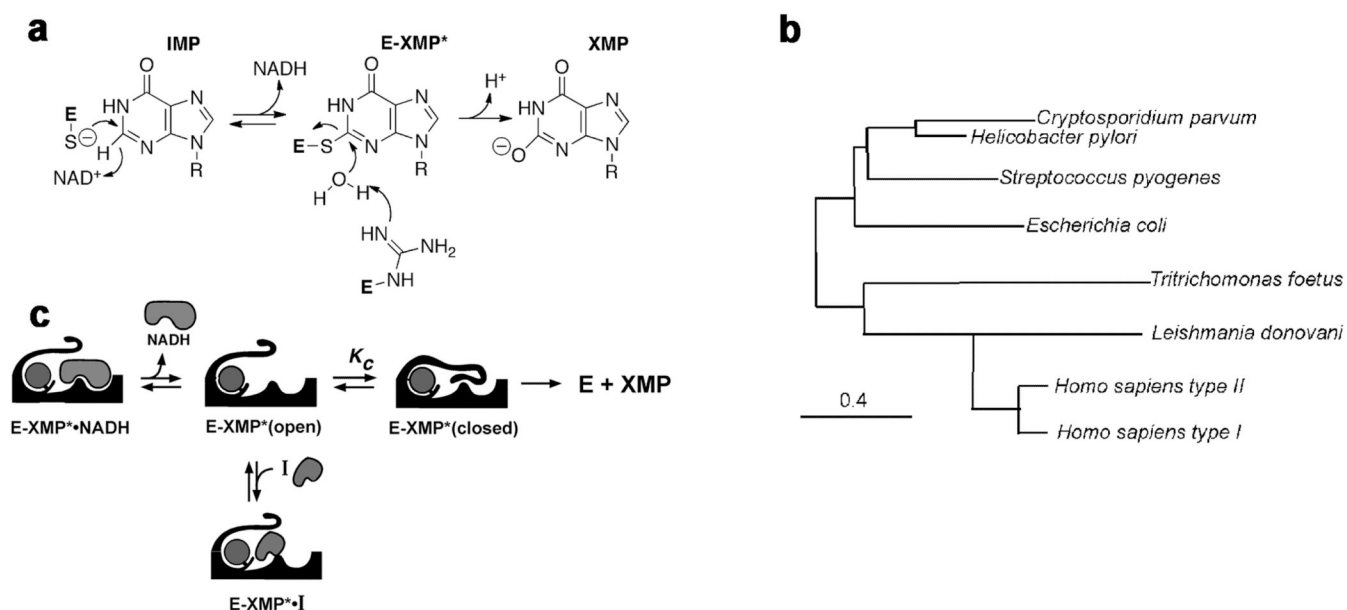

Figure 1. The IMPDH reaction

a. Chemical mechanism: a conserved Cys attacks C2 of IMP and hydride is transferred to NAD^+ producing the covalent intermediate E-XMP*. E-XMP* is hydrolyzed with a conserved Arg residue acting as a general base to produce XMP. **b.** The hydride transfer reaction proceeds in an open enzyme conformation. After NADH departs, a mobile flap folds into the NAD site, carrying the catalytic Arg into the active site. Inhibitors compete with the flap, so the equilibrium between open and closed states is a determinant of inhibitor affinity. **c.** Phylogenetic tree of IMPDHs. Constructed as described in (Min, et al., 2008).

Figure 2. Structures of IMPDH inhibitor binding sites

a. Structure of C64. **b.** Structure of the *Cp*IMPDH•IMP•C64 complex (salmon; PDB accession 3KHJ (MacPherson, et al.)) and resistant IMPDHs from *T. foetus* (green; 1LRT (Gan, et al., 2002)) and Chinese hamster (blue; 1JR1, nearly identical to human IMPDH2 (Sintchak, et al., 1996)). Residues within 5 Å of C64 are displayed. C64 is shown in gray with a transparent surface; *Cp*IMPDH residues are labeled; residue from the adjacent monomer are denoted with a '. Residues Thr221 and Glu329 are hidden under C64. **c.** The surface of the NAD binding site rendered by conservation of residues in prokaryotic IMPDHs from *T. foetus*, *C. parvum*, *H. pylori*, *B. burgdorferi*, *S. pyogenes* and *Ec*IMPDH. Dark magenta, 100% conserved; tan, 63%; dark cyan, 25%. The NAD analog tiazofurin adenine dinucleotide (TAD) is light gray. The tiazofurin binding site is circled in blue and the ADP binding site is circled in red. **d.** The surface of the C64 binding site rendered by conservation of residues in sensitive IMPDHs from *C. parvum*, *H. pylori*, and *B. burgdorferi*, as well as the S250A/L444Y variant of *Ec*IMPDH. Ser164, Met326 and Ser354

are within 5 Å of **C64**; Val143 is 8 Å away. Dark magenta, 100% conserved; tan, 60%; dark cyan, 20%. **C64** depicted in ball-and-stick in light gray and IMP is shown in stick in dark gray. **e.** The surface of the **C64** binding site rendered by conservation of residues in *Cp*IMPDH and IMPDHs from 19 pathogenic bacteria: *Acinetobacter baumannii* (wound infection), *Bacillus anthracis* (anthrax), *Bacteroides fragilis* (peritoneal infections), *Brucella abortus/melitensis/suis* (brucellosis), *B. burgdorferi* (Lyme disease), *Burkholderia cenocepacia* (infection in cystic fibrosis), *Bu. mallei* (glanders), *Bu. pseudomallei* (melioidosis), *Campylobacter jejuni* (food poisoning), *C. lari* (food poisoning), *Coxiella burnetii* (Q fever), *Francisella tularensis* (tularemia), *H. pylori* (gastric ulcer/stomach cancer), *Listeria monocytogenes* (listeriosis), *Staphylococcus aureus* (major cause of nosocomial infection), *S. pyogenes* (major cause of nosocomial infections) and *S. pneumoniae* (pneumonia). Dark magenta, 100% conserved; tan, 63%; dark cyan, 25%. Alignments were constructed with CLUSTALW2 and molecular graphics images were produced using the UCSF Chimera package from the Resource for Biocomputing, Visualization, and Informatics at the University of California, San Francisco (supported by NIH P41 RR-01081) (Pettersen, et al., 2004). Supported by Figure S3.

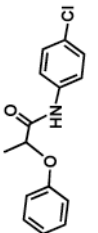

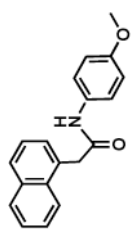

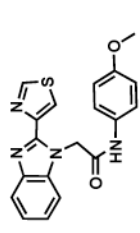

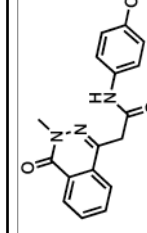

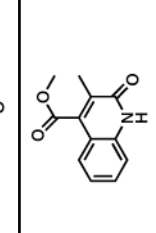

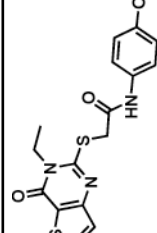

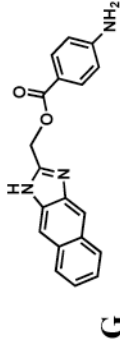

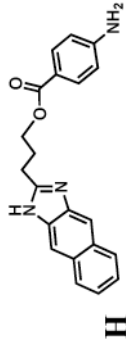

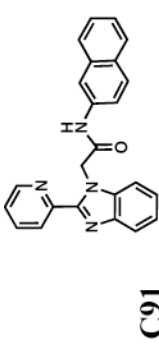

Figure 3. C91 inhibits *H. pylori* growth

a. Compound **C91** in DMSO was added to freshly diluted stationary cultures of *H. pylori* strain G27 in Brucella broth. Samples were removed at the indicated time points, diluted, and plated to determine bacterial proliferation/survival. Each point is the average of duplicate determinations; a representative of three experiments is shown. Black, DMSO alone. **C91** concentrations: purple, 2 μ M; blue, 7 μ M; green, 20 μ M; orange, 60 μ M; red, 200 μ M. **b.** Compound **C91** was added to freshly diluted cultures of *E. coli* MG1655 in Luria broth. Each point is the average of three determinations; the standard deviations are smaller than the point. Black, DMSO alone. **C91** concentrations: orange, 100 μ M; red, 200 μ M. Supported by Figure S4.

Table 1

Inhibition of IMPDHs by compounds A–H. These compounds (100 μ M) do not inhibit *Ec*IMPDH, *Tj*IMPDH and *Ld*IMPDH. The errors on the IC_{50} values were less than 10% unless otherwise noted. "Intrinsic" values (adjusted for the fraction of enzyme in the open conformation) are shown in parentheses.

Compound	IC_{50} (μ M)				
	<i>Cp</i> IMPDH ^a	<i>Hp</i> IMPDH	<i>Bb</i> IMPDH	<i>Sp</i> IMPDH	<i>Ec</i> IMPDH-S250A/L44Y

^a data from (Umejiego, et al., 2008);

^b determined with a tight-binding equation;

^c error \leq 37%.

^d error = 73%; error = 52%. Supported by Figure S1.

Table 2
The conformational contribution to potency of IMPDH inhibitors

As shown in Figure 1b, inhibitors compete with the mobile flap for the vacant NADH site. Therefore the observed affinity will be determined by the intrinsic affinity of the inhibitor for the NAD site and the affinity of the flap, i.e., $K_{\text{int}} = K_i / (1 + K_c)$, where K_{int} is the intrinsic affinity, K_i is the measured inhibition constant and K_c is the conformational equilibrium determined as described in Materials and Methods.

Enzyme	$K_{i,\text{Tzf}}$ (mM)	$K_{i,\text{ADP}}$ (mM)	K_c	$K_{\text{int,Tzf}}$ (mM)	$K_{\text{int,ADP}}$ (mM)
<i>Cp</i> IMPDH ^a	1.5 ± 0.1	42 ± 6	4	0.3	8
<i>Hp</i> IMPDH	1.3 ± 0.1	6.0 ± 0.5	1	0.7	3
<i>Bh</i> IMPDH	1.1 ± 0.2	7.4 ± 0.6	0.7	0.7	4
<i>Sp</i> IMPDH	8 ± 1	13 ± 2	7	0.7	2
<i>Tf</i> IMPDH ^a	69 ± 9	31 ± 2	140	0.5	0.2
<i>Ec</i> IMPDH	5.3 ± 0.6	10 ± 2	9	0.5	1
<i>Ec</i> IMPDH-S250A	2.5 ± 0.3	0.10 ± 0.01	1.5	1	0.04
<i>Ec</i> IMPDH-S250A/L444Y	1.1 ± 0.2	4.1 ± 0.7	2.3	0.3	1
<i>h</i> IMPDH2 ^a	1.3 ± 0.1	9 ± 2	≤ 0.2	1.3	9
<i>L</i> IMPDH	8.3 ± 0.7	15 ± 2	2.3	2.5	5
