Occurrence in Saccharomyces cerevisiae of a gene homologous to the cDNA coding for the α subunit of mammalian G proteins

(GTP-binding proteins/signal transduction/ras protein)

ABSTRACT From cross-hybridization studies with cDNAs that code for the α subunits of rat brain guanine nucleotidebinding regulatory (G) proteins, we have isolated a gene from yeast Saccharomyces cerevisiae encoding an amino acid sequence that is highly homologous to the α subunit of the G protein that mediates inhibition of adenylate cyclase $(G_{i\alpha})$ from rat brain. The gene, tentatively designated as GPA1, contains a contiguous, single open reading frame of 1416 nucleotides that codes for a protein of 472 amino acids with a calculated M_r of 54,075. The predicted amino acid sequence of the protein encoded by the GPA1 gene (tentatively designated as G protein 1α or GP1 α) is remarkably homologous to the amino acid sequence of rat brain $G_{i\alpha}$ and the α subunit of the G protein of unknown function $(G_{o\alpha})$; the primary structure of the sites for GTP hydrolysis as well as GTP interaction are nearly identical. The main difference in the molecular sizes of yeast GP1 α (472 amino acids) and rat brain $G_{i\alpha}$ (355 amino acids) is due to the presence of a stretch of 110 extra amino acid residues in yeast GP1 α , which are inserted near the NH₂-terminal one-third of mammalian $G_{i\alpha}$. From blot-hybridization analysis, the size of the GP1 α mRNA was estimated as 1.7 kilobases.

G proteins are a family of guanine nucleotide-binding proteins that are involved in a variety of receptor-mediated signal transduction systems (1). Thus, G_s and G_i are involved in hormonal stimulation and inhibition, respectively, of adenylate cyclase activity (1, 2), whereas transducin (G_t), which is present predominantly in the retinal rod outer segment, regulates cGMP phosphodiesterase activity (3). Another G protein, G_o , which has recently been reported in several tissues (4–7), may be involved in neuronal responses, but its precise function has not yet been clarified. Furthermore, recent evidence suggests the involvement of G proteins in the activation of phospholipase C (8–12) and the gating of K⁺ channels (13).

In a previous report (14), we described the cloning and sequence determination of cDNAs that code for the α subunits of G_s, G_i, and G_o from rat C6 glioma cells. The predicted amino acid sequences of the α subunits of G_s (G_{s α}) and G_i (G_{i α}) contain 394 and 355 amino acid residues, respectively, whereas the clone of the α subunit of G_o (G_{o α}) encodes a sequence of 310 amino acid residues that lack the NH₂ terminus. The amino acid sequence of G_{s α} from rat brain is almost identical (about 99% homologous) to that of bovine adrenal G_{s α} published by Robishaw *et al.* (15) and to that of bovine brain G_{s α} by Nukada *et al.* (16). On the other hand, the sequence of rat brain G_{i α} (14) is about 89% homologous with the bovine brain G_{i α} sequence reported by Nukada *et al.* (17).

Another family of GTP-binding proteins, the ras family, is widely distributed among eukaryotes. This family also consists of several closely related proteins (e.g., those encoded by H-ras, K-ras, and N-ras in mammalian tissues) and is highly conserved among a variety of species including mammals (18-22), Drosophila (23), slime molds (24), and the yeasts Saccharomyces cerevisiae (25, 26) and Schizosaccharomyces pombe (27). In the case of S. cerevisiae, genetic evidence suggests that the RAS2 gene is involved in the activation of adenylate cyclase (28, 29). From this finding, it was speculated that RAS2 in S. cerevisiae is the counterpart of mammalian G_s (28, 30).

However, a remarkable homology between the primary structures of rat and bovine $G_{s\alpha}$ prompted us to search for the presence of G proteins in S. cerevisiae. In this paper, we describe the isolation and sequence determination of a gene from S. cerevisiae, which codes for a protein that is highly homologous to rat brain $G_{i\alpha}$ and $G_{o\alpha}$. To our knowledge, this is the first demonstration of the occurrence of a G protein in yeast.

MATERIALS AND METHODS

Yeast Strain and Media. S. cerevisiae haploid strains pep4 (a, ade3, leu1, pep4) and 106A (α , arg) were cultured in a YPD medium (2% polypeptone/1% yeast extract/2% glucose).

Southern and RNA-Hybridization Blot Analysis. Yeast DNA was prepared from the cells of S. cerevisiae pep4 essentially as described by Cryer et al. (31). Southern blot analysis was performed as described by Southern (32) using low- and high-stringency hybridization conditions. Lowstringency hybridization was carried out at 37°C in $5\times$ NaCl/Cit (1× NaCl/Cit contains 0.15 M NaCl and 15 mM sodium citrate)/20 mM sodium phosphate, pH $7.0/1 \times$ Denhardt's solution (0.02% bovine serum albumin/0.02% polyvinylpyrrolidone/0.02% Ficoll)/heat-denatured calf thymus DNA (100 µg/ml)/0.1% NaDodSO₄/10% dextran sulfate/20% (vol/vol) formamide. For high-stringency conditions, the incubation temperature was increased to 42°C, and the concentration of formamide was increased to 50% (vol/vol). The filters were washed with $5 \times \text{NaCl/Cit}/0.1\%$ NaDodSO₄ at room temperature and then with $0.1 \times$ NaCl/Cit/0.1% NaDodSO₄ at 37°C.

DNA fragments of the rat G protein cDNAs used as probes for cross-hybridization analysis of yeast genomic DNA were the 1.2-kilobase (kb) *Eco*RI fragment of λ GX3 (14), which carries almost the entire rat $G_{o\alpha}$ cDNA, and the 0.7-kb *Eco*RI-*Bam*HI fragment of λ GX13 (14), which contains the NH₂-terminal one-third of the rat $G_{i\alpha}$ cDNA. The 1.9-kb *Eco*RI fragment containing the *GPA1* gene was also used as a probe for Southern blot analysis of yeast genomic DNA (see

The publication costs of this article were defrayed in part by page charge payment. This article must therefore be hereby marked "*advertisement*" in accordance with 18 U.S.C. §1734 solely to indicate this fact.

Abbreviations: G proteins, guanine nucleotide-binding regulatory proteins; G_s and G_i , G proteins that mediate stimulation and inhibition, respectively, of adenylate cyclase; G_o , a G protein of unknown function; G_t , transducin, a G protein that regulates cGMP phosphodiesterase activity in phototransduction; $G_{s\alpha}$, $G_{i\alpha}$, $G_{o\alpha}$, and $G_{t\alpha}$, α subunits of G_s , G_i , G_o , and G_t , respectively.

Results). ³²P-labeled probes were prepared by the primer extension method described by Feinberg and Vogelstein (33).

Yeast RNA for blot-hybridization analysis was prepared as follows. Strain 106A was cultured to logarithmic phase, and spheroplasts were prepared in the same manner as for the preparation of DNA. The spheroplasts were lysed by the addition of diethyl pyrocarbonate and NaDodSO₄ to final concentrations of 1% (vol/vol) and 1% (wt/vol), respectively. The mixture was immediately extracted twice with phenol/chloroform (1:1; saturated with 10 mM Tris·HCl, pH 7.4/100 mM NaCl/1 mM EDTA). Two volumes of ethanol were added, and the precipitates were dissolved in 10 mM Tris·HCl, pH 7.4/1 mM EDTA. Poly(A)⁺ RNA was obtained by oligo(dT)-cellulose column chromatography, and blothybridization analysis was performed as described (34).

Screening of the Yeast Genomic Library. The procedure of Hanahan and Meselson (35) was used to screen the yeast genomic library kindly provided by Botstein (36). The hybridization conditions were similar to those of genomic Southern analysis.

DNA Sequence Analysis. Nucleotide sequences were determined by using bacteriophage M13 vectors and the dideoxynucleotide chain-termination method (37).

RESULTS

Presence of Sequences Homologous to cDNAs Coding for the Rat Brain G Protein α Subunits in S. cerevisiae. We searched for sequences homologous to cDNAs for mammalian $G_{i\alpha}$ and $G_{o\alpha}$ in S. cerevisiae DNA by Southern hybridization analysis. Several bands that hybridized with the ³²P-labeled $G_{i\alpha}$ and $G_{o\alpha}$ cDNAs were detected when S. cerevisiae DNA was digested with several restriction endonucleases and analyzed by Southern hybridization under low-stringency conditions (data not shown). This suggests the presence of G-protein homologous genes in yeast.

Cloning of the Yeast Gene Homologous to the Rat Brain $G_{i\alpha}$ cDNA. The genomic library of *S. cerevisiae* constructed by Carlson and Botstein (36) by cloning the partial *Sau3A* digests of yeast DNA in vector YEp24 was screened by colony hybridization using the ³²P-labeled rat $G_{i\alpha}$ and $G_{o\alpha}$ cDNA probes. Twelve colonies were isolated from screening $\approx 6 \times 10^4$ clones under low-stringency conditions of hybridization. The plasmid DNAs were prepared, digested with restriction endonucleases, and analyzed by Southern hybridization. One of the clones, pMN10, which contains about 12.5 kb of yeast genomic DNA, hybridized with not only the $G_{i\alpha}$ but also with the $G_{o\alpha}$ probes.

The DNA insert of pMN10 was cleaved with several restriction endonucleases and was again analyzed by Southern hybridization using a mixture of rat $G_{i\alpha}$ and $G_{o\alpha}$ cDNAs

as the probe. It was found that the yeast sequence homologous to the mammalian $G_{i\alpha}$ and $G_{o\alpha}$ resides within the 1.9-kb *Eco*RI fragment of pMN10. This fragment was then subcloned in the *Eco*RI site of pUC8 to yield pGI1.

Nucleotide Sequence Analysis. The physical restriction map of pGI1, which harbors the yeast G-protein homologous gene (tentatively designated as GPA1), is shown in Fig. 1, together with the strategy for DNA sequence determination. The nucleotide sequence (1924 bp) and deduced amino acid sequence are shown in Fig. 2. The DNA sequence contains an open reading frame of 1416 nucleotides coding for a protein of 472 amino acid residues (including the initiator methionine) with a calculated M_r of 54,075. The sequence around the ATG initiator codon (ATAATGG) is a favorable one proposed by Kozak (38)—i.e., a purine in position -3and a guanosine in position +4. Upstream of the ATG codon, several putative promoter sequences (39) were found (see Fig. 2). The open reading frame ends at the TGA stop codon (positions 1417–1419). Downstream of the stop codon, there is a sequence that agrees well with the consensus sequence for polyadenylylation in yeast (40) (positions 1620–1626).

Comparison of the Amino Acid Sequence of Yeast GP1 α with Those of Rat Brain $G_{i\alpha}$ and $G_{o\alpha}$. The deduced amino acid sequence of yeast GP1 α (GPA1-encoded protein) is highly homologous with those of rat brain $G_{i\alpha}$ and $G_{o\alpha}$. As shown in Fig. 3, the homology is most remarkable in the region of GTP hydrolysis (amino acid residues 43–56), where the amino acid sequence of yeast GP1 α is completely identical with rat brain $G_{i\alpha}$. The region responsible for GTP binding (amino acid residues 384–396) was also highly homologous; 12 out of 13 amino acids were identical in yeast GP1 α and rat brain $G_{i\alpha}$. Another region of homology was found in amino acid residues 321–336 where a sequence of 16 contiguous amino acids was completely identical in yeast GP1 α and rat $G_{i\alpha}$.

Disregarding the sequence of a stretch of 110 amino acids that is unique to yeast GP1 α (residues 126–235), the overall homology between yeast GP1 α and rat brain G_{i α} is 45% (164 out of 362 amino acids are identical), and the homology is 64% when conservative amino acid replacements are regarded as homologous. The amino acid sequence of rat brain G_{o α} is 43% identical with that of yeast GP1 α and is 66% homologous when the conservative amino acid replacements are regarded as homologous. On the other hand, the homologies of the nucleotide sequence of yeast GP1 α with that of rat brain G_{i α} and G_{o α} are 54% and 52%, respectively.

Southern Blot Analysis of Yeast Genomic DNA with the Yeast GPA1 Gene. We have analyzed yeast genomic DNA digested with various restriction endonucleases by using the ³²P-labeled 1.9-kb EcoRI fragment of pGI1 as a probe. The fragment contains the entire sequence of the yeast GPA1

FIG. 1. Restriction map and sequence strategy for the pGI1 plasmid. The wavy and straight lines show vector DNA and inserted yeast DNA, respectively. The amino acid coding region is represented by an open bar. The arrows indicate the direction and extent of the DNA sequence that was determined by the dideoxynucleotide chain-termination method (37).

FIG. 2. Nucleotide and predicted amino acid sequence of the *GPA1* gene. Numbering of the nucleotide sequence begins at the first nucleotide in the open reading frame. The deduced amino acid sequence is shown below the nucleotide sequence. The putative "TATA" boxes and the polyadenylylation signal are boxed.

gene. Only a single band was detected in each lane even under low-stringency conditions (Fig. 4).

Detection of Transcripts. To see the expression of the yeast *GPA1* gene, we have carried out blot-hybridization analysis of $poly(A)^+$ mRNA prepared from exponentially growing cells of yeast strain 106A by using the ³²P-labeled 1.9-kb *Eco*RI fragment of pGI1. As shown in Fig. 5, a single band of about 1.7 kb was detected. This indicates that the *GPA1* gene was transcribed in growing cells.

DISCUSSION

This paper describes the isolation of a gene from S. cerevisiae whose predicted amino acid sequence is highly homologous to that of rat brain $G_{i\alpha}$ and $G_{o\alpha}$ (Fig. 3). The sequence is less homologous to that of rat brain $G_{s\alpha}$.

The molecular size of the predicted yeast GP1 α (472 amino acids) is considerably larger than rat brain $G_{i\alpha}$ (355 amino acids). The difference in molecular sizes of yeast GP1 α and mammalian $G_{i\alpha}$ is mainly due to the presence of a stretch of 110 extra amino acids in yeast GP1 α , which is inserted at the NH₂-terminal one-third of the molecule. The nucleotide sequence of this region does not seem to be an intervening sequence since no consensus sequence for splicing signals (42) (i.e., for donor and acceptor sites as well as the TACTAACA sequence) was detected in this region. The inserted sequence of 110 amino acids was analyzed by a computer search for possible homology with known protein sequences compiled in the protein sequence database (43); however, no apparent homology was detected with any of the reported sequences. This sequence resides within the domain of mammalian G proteins, which is assumed to be the site interacting with an amplifier or an effector molecule (44).

Comparison of the predicted amino acid sequence of the yeast GP1 α protein with mammalian G proteins (see Fig. 3) reveals a strong conservation in the region of the GTP binding and hydrolysis sites (14). The amino acid residue of mammalian $G_{i\alpha}$, $G_{o\alpha}$, and $G_{t\alpha}$ that is the site of ADP ribosylation by pertussis toxin—i.e., cysteine at the fourth residue from the COOH terminus—has been replaced by isoleucine, which indicates that the yeast GP1 α protein is probably refractory to the modification by islet-activating protein. On the other hand, the sequence around Arg-297 of yeast GP1 α is highly homologous with the sequence around Arg-201 of rat brain $G_{s\alpha}$, which is the ADP-ribosylation site for cholera toxin.

Recently much interest has been focused on the structure of G proteins and their function in receptor-mediated transmembrane signaling systems. The cDNA sequences for the α subunits of G_s (14–16), G_i (14, 17), G_o (14), and G_t (45–48) have been determined. The nucleotide and amino acid sequences are highly homologous among these different G proteins, and they are highly conserved among different species. Over 99% homology was observed in the amino acid sequences of rat brain G_{sa} and G_{sa} from bovine brain or

FIG. 3. Alignment of the predicted amino acid sequence of $GP1\alpha$ with those of the α subunits of mammalian G proteins. Sets of identical or conservative residues are enclosed within solid lines. Conservative amino acid substitutions are grouped as follows: C; S, T, P, A, and G; N, D, E, and Q; H, R, and K; M, I, L, and V; and F, Y, and W (41).

adrenal cells (14–16). The remarkable conservation of amino acid sequences of G proteins among different species suggests the ubiquitous occurrence of G proteins.

Another family of GTP-binding proteins, the ras family, which may also be involved in biosignal transduction, is also widely distributed and is highly conserved. In yeast S. cerevisiae and Schizosaccharomyces pombe, the RASI and RAS2 genes (25, 26) and the ras1 gene (27), respectively, have been identified as mammalian ras homologous genes. (RAS1

FIG. 4. Southern blot analysis of S. cerevisiae DNA. Genomic DNA isolated from S. cerevisiae strain pep4 was digested with restriction endonucleases and electrophoresed in a 0.8% agarose gel. DNA was denatured, transferred to a nitrocellulose filter, and hybridized with the ³²P-labeled 1.9-kb EcoRI fragment of pGI1 under high (A)- and low (B)-stringency conditions. Each lane contained about 5 μ g of DNA. Restriction endonucleases used were Bgl II (lanes 1), EcoRI (lanes 2), HindIII (lanes 3), and Pst I (lanes 4). Sizes (in kb) of the markers are indicated at the right.

and RAS2 are S. cerevisiae genes homologous to mammalian ras while ras1 represents a ras homologous gene of Schizosaccharomyces pombe.) Amino acid sequences predicted from the DNA sequences of the yeast ras genes show a high level of homology with the protein sequences of the mammalian ras family, but the sizes of the RAS1 (309 amino acids) and RAS2 (322 amino acids) proteins (25) are considerably larger than the mammalian ras proteins (189 amino acids; refs. 18–22).

Initially, it was hoped that the function of mammalian ras proteins would be elucidated by studying the function of the yeast *ras* gene. However, subsequent genetic and biochemical studies on the function of yeast ras proteins have

FIG. 5. Blot-hybridization analysis of S. cerevisiae poly(A)⁺ RNA. Poly(A)⁺ RNA (20 μ g) isolated from strain 106A was electrophoresed in a 1.2% formaldehyde/agarose gel. RNA was transferred to a nitrocellulose filter and hybridized with the ³²P-labeled 1.9-kb *Eco*RI fragment of the pGII plasmid under high-stringency conditions. Sizes (in kb) of the DNA markers are indicated at the left.

revealed that RAS2 is involved in the regulatory mechanism of adenylate cyclase activity (28) in a fashion similar to mammalian $G_{s\alpha}$. These results have led to the supposition that ras proteins in yeast may be counterparts of mammalian G proteins (28, 30).

In view of the strong conservation of the amino acid sequence of $G_{s\alpha}$ in different species, however, we thought that yeast might possess a G protein family in addition to the ras family. This has turned out to be true as evidenced by the isolation of the *GPA1* gene in *S. cerevisiae* that is described in this paper. Our preliminary results suggest that other G proteins may also occur in *S. cerevisiae*. Studies on the function of G proteins in yeast may throw more light on the role of the G and ras proteins in signal transduction in mammalian cells.

We thank Dr. S. Nagata for his valuable advice on the cloning methods and Miss T. Obara for carrying out several experiments. We also thank Drs. A. Miyajima, K. Matsumoto, K. Kaibuchi, and K. Arai and Mrs. I. Miyajima for helpful discussions.
