Abstract We investigated phylogenetic affiliation, occurrence of virulence genes and quinolone resistance in 109 integron-containing strains of *Escherichia coli* isolated from a wastewater treatment plant. Selection for integron-bearing strains caused a shift toward phylogroup D, which was most numerous, followed by A, B1 and B2. Phylogroups D and B2, both of which are reported to include virulent extraintestinal pathogens, made up 50.5% of all isolates and were present in every stage of wastewater treatment, including final effluent. Diarrheagenic pathogens made up 21% of the strains. The average virulence factor genes score was low (1.40) and the range was from 0 to 5. Quinolone and fluoroquinolone resistance was observed in 56.0% and 50.4% of the strains, respectively; however, it was not associated with virulence factor score. Although the average virulence factor score was low, 17.4% of strains had three and more virulence genes. They were isolated mostly from raw sewage, but 30% of them were cultured from final effluent. Release of multiresistant integron-bearing *E. coli* strains with virulence traits into the environment may create potential threat and be of public health concern.

Introduction

Escherichia coli is a well recognized etiological agent of community-acquired and nosocomial infections. Clinical categories of *E. coli* include commensal, intestinal pathogenic and extraintestinal pathogenic (ExPEC) strains. Intestinal pathogenic isolates comprise enterohemorrhagic (EHEC), enteropathogenic (EPEC), enteroaggregative (EAEC), enterotoxigenic (ETEC), enteroinvasive (EIEC) and diffusely adherent *E. coli* (DAEC). ExPEC strains, which are responsible for several infectious diseases, including urinary tract (uropathogenic strains, UPEC), bacteremia and neonatal meningitis (MNEC, meningitis-associated *E. coli*), possess virulence factors like adhesins, toxins, iron acquisition systems, polysaccharide coats and invasins (Kaper et al. 2004). The virulence genes in both diarrheagenic and extraintestinal strains are often located within mobile genome elements, e.g. plasmids, transposons, bacteriophages, and pathogenicity islands (Kaper 2005). This phenomenon may contribute to spreading of virulence traits among related bacterial species. It has been shown that pathogenic *E. coli* may be derived from commensal strains by acquisition of chromosomal or extra-chromosomal virulence operons (Ochman et al. 2000). Phylogenetically, *E. coli*

strains are divided upon amplification of genes *chuA* coding for the heme transport protein, *yjaA*, initially identified in the complete genome sequence of *E. coli* K-12 encoding a hypothetical protein, and a non-coding region TSPE4.C2 (Clermont et al. 2000). The patterns of amplicons creates four groups A, B1, B2 and D. ExPEC strains are derived from group B2 and to a lesser extent D, commensal from A and B1, and diarrheagenic from A, B1 and D (Johnson and Stell 2000; Hamelin et al. 2007). However, the relative predominance of different phylogroups may vary due to geographical location, the site of infection and the level of antibiotic resistance (Duriez et al. 2001; Bukh et al. 2009). Several studies on clinical *E. coli* have demonstrated relationship between antibiotic resistance and low prevalence of virulence factors and suggested that quinolone resistance may be directly associated with the loss of virulence (Horcajada et al. 2005; Takahashi et al. 2009; Kawamura-Sato et al. 2010). The mechanism underlying this correlation is not clear, yet, but probably a particular genetic background is required for mutations leading to quinolones resistance (Kawamura-Sato et al. 2010). Soto et al. (2006) have shown that quinolones can induce in vitro partial or total loss of a pathogenicity island containing hemolysin and cytotoxic necrotizing factor genes, but other studies have not confirmed that phenomenon (Sabaté et al. 2008).

Wastewater treatment plant creates excellent conditions for dissemination of resistance genes through horizontal gene transfer facilitated by plasmids and transposons (Schlüter et al. 2007). From wastewater treatment plants bacteria can return to aquatic and land habitats, and affect human and animals. Resistance genes are often assembled in integrons, which are natural systems mediating the capture of gene cassettes coding for antibiotic resistance. Integrons are frequently embedded in mobile DNA elements such as transposons and conjugative plasmids that enable them to spread horizontally through bacterial populations (Fluit and Schmitz 2004). Recently, it has occurred that resistance due to slow reversibility can persist long in bacterial communities even if the selective pressure imposed by antibiotic usage is reduced (Andersson and Hughes 2010). Moreover, the integron-mediated resistance, can be silenced in bacterial population at no biological cost (Guerin et al. 2009). Multidrug resistance of *Enterobacteriaceae* strains is associated with the presence of integrons (Leverstein-van Hall et al.

2003). As the economic and clinical impact of *E. coli* infections is considerable, monitoring of non-clinical reservoirs of these bacteria with virulence and resistance determinants has become a serious concern worldwide.

The aim of the study was to analyze the distribution of phylogenetic groups and occurrence of virulence genes in relation to quinolone resistance in integron-bearing strains of *E. coli* isolated from the sewage in wastewater treatment plant of a city with population of about 550 thousand.

Materials and methods

Sampling and *E. coli* isolation

Sewage samples were taken from a municipal wastewater treatment plant three times: in December 2008, April 2009 and July 2009. The samples were taken from (i) raw sewage in primary sedimentation tank, (ii) aeration tank and (iii) final effluent. The sewage was collected to sterile containers at the depth of 0.3 m and the distance of one meter from the side of the respective sampling sites. Serial decimal dilutions of the samples were prepared in 0.9% NaCl, inoculated onto BrillianceTM *E. coli*/coliform Selective Agar (Oxoid) and incubated overnight at 44°C. Purple colonies were picked from the medium and used in further experiments. Identification was done with API 20E (bioMérieux).

ERIC PCR typing

The ERIC PCR was done according to Versalovic et al. (1991) with primers ERIC 1 and ERIC 2. The PCR products were separated in 1.5% agarose gel, stained with ethidium bromide and digitalized with Bio-Print v. 99 gel documentation system (Vilbert-Lourmat). The electrophoretic patterns were analyzed by using GelCompar II 3.5 software (Applied Maths). Similarity between fingerprints was calculated with the Dice coefficient. Cluster analysis was performed using the unweighted pair-group method with average linkages (UPGMA).

Identification of integrase genes

Genomic DNA was isolated by the boiling lysate method. Integron classes were determined by

multiplex PCR. The sequences of primers targeting *intI1*, *intI2* and *intI3* integrase genes were recommended by Dillon et al. (2005). Amplification involved an initial denaturation (94°C, 5 min) followed by 30 cycles of denaturation (94°C, 1 min), annealing (59°C, 1 min) and extension (72°C, 1 min) with a final extension step (72°C, 8 min). Negative control contained sterile deionized water instead of template DNA. To exclude false positive results, the PCR products of the expected sizes (160 bp for *intI1*, 788 bp for *intI2* and 979 bp for *intI3*) were sequenced in a 3130xl Genetic Analyzer (Applied Biosystems). The amplicon sequences were compared against GenBank database by using BLAST (Basic Local Alignment Search Tool).

Phylogenetic analysis

A, B1, B2 and D phylogenetic groups were determined in triplex PCR method (Clermont et al. 2000) with primers ChuA.1, ChuA.2, YjaA.1, YjaA.2, TspE4C2.1, and TspE4C2.2. The PCR reaction consisted of initial denaturation for 5 min at 94°C and 30 cycles of 30 s at 94°C, 30 s at 55°C and 30 s at 72°C followed by a final extension step of 7 min at 72°C.

Detection of genes characteristic of diarrheagenic pathotypes of *E. coli*

Multiplex PCR assays according to Aranda et al. (2004) were done to detect typical and atypical enteropathogenic *E. coli* (EPEC), enteroaggregative *E. coli* (EAEC) enterotoxigenic *E. coli* (ETEC), enteroinvasive *E. coli* (EIEC), and Shiga toxin-producing *E. coli* (STEC) isolates. The targeted genes were: *eae* and *bfpA* for EPEC, CVD432 for EAEC, heat-labile (LT) and heat-stable (ST) enterotoxin genes for ETEC, *ipaH* for EIEC, and *stx1* and *stx2* for STEC.

Identification of virulence genes

Virulence genes characteristic for extraintestinal *E. coli* were detected by PCR assays. The following genes were targeted using primers and PCR conditions recommended by Johnson and Stell (2000): *fyuA* (encoding yersiniabactin receptor), *iutA* (aerobactin receptor gene), *hlyA* (haemolysin A gene), *papA*

(P fimbriae subunit gene), *sfaS* (S fimbriae subunit gene), *focG* (F1C fimbriae subunit gene), and *cnf1* (cytotoxic necrotizing factor gene). VF (virulence factor) gene score was determined as a total number of virulence genes per strain.

Determination of antimicrobial susceptibility including quinolone and fluoroquinolone resistance

Antibiotic resistance patterns were determined by disc diffusion method according to Clinical and Laboratory Standards Institute guidelines (CLSI, 2009). Isolates were tested for susceptibility to antibiotics representing aminoglycosides, amphenicols, carbapenems, penicillins, cephalosporins, quinolones, fluoroquinolones, sulphonamides, and tetracyclines. Quinolones were represented by nalidixic acid and fluoroquinolones by norfloxacin and ciprofloxacin.

Statistical analysis

Occurrence of virulence factors among phylogenetic groups were compared by using Fisher's exact test. VF scores were compared with the Mann–Whitney *U* test (Statistica 9.1, StatSoft). *P* < 0.05 was considered to indicate statistical significance.

Results and discussion

E. coli isolation and identification of the integrase genes

Altogether, 973 isolates of *E. coli* were recovered from the wastewater; 109 of them harboured integrons in their genomes and were used in further experiments.

PCR amplification of the integrase genes representative for three classes of integrons revealed the presence of *intI1* in 105 strains (10.8%). Two strains (0.2%) had *intI2* gene and two isolates (0.2%) harboured both *intI1* and *intI2*. No integron of class 3 was found. Integrons of class 2 were present in strains belonging to phylogroup A (2 strains) and D (2 strains). Seventy-five percent of *intI*-positive strains originated from raw sewage, 10% from aeration tank and 15% from final effluent. They

made 11% of the total number of *E. coli* strains isolated from the wastewater samples.

Similar values have been reported by da Silva et al. (2007), who noted 10% frequency of occurrence of class 1 integrons among *E. coli* strains isolated from an urban wastewater treatment plant in Portugal. On the other hand, Moura et al. (2007) have noticed higher incidences of integron carriage among *Enterobacteriaceae* and *Aeromonadaceae* originated from a slaughterhouse wastewater treatment plant. The mean percentage of integrase-positive strains reached 35%, with *intI1* gene present in 30.7% of strains, *intI2* gene in 4.5% and both genes in one isolate (0.3%). Integrons have been also detected in multi-resistant *E. coli* isolated from raw and treated municipal wastewaters used for irrigation in agriculture (Pignato et al. 2009).

The frequencies of integron-positive strains in our study are comparable to those obtained previously for *E. coli* strains isolated from healthy subjects without recent antibiotic exposure: 11% for class 1 integrase, 3% for class 2 integrase and 0.6% for both class 1 and 2 integrases (Skurnik et al. 2005). Our results are also similar to the incidences of *intI*-positive strains isolated from Seine estuary, which reached 11% (Laroche et al. 2009).

The frequencies of integron-carrying *E. coli* isolated from clinical specimens are noticeably higher

and reach as much as 27.6% in bloodstream infections (Daikos et al. 2007) and 44.8% in urine and stool strains (Japoni et al. 2007).

Clonal relatedness of *E. coli* strains

To exclude the possibility of analyzing strains clonally identical, we performed ERIC PCR typing. The fingerprints of *E. coli* isolates consisted of 1–21 bands ranging in size from 110 to 3500 bp. None of the strains shared identical ERIC PCR pattern.

Phylogenetic analysis

The most abundant phylogroup among *intI*-positive *E. coli* strains was D (36.7%), followed by A (30.3%), B1 (19.3%), and B2 (13.8%) (Table 1). A set of 150 *E. coli* strains randomly picked from the total pool of isolates (973) showed noticeably different pattern of phylogenetic group distribution: 47.0% of strains belonged to group A, whereas groups D, B2 and B1 were represented by 24.7, 23.3 and 10.0%, respectively. We observed that the selection for integron-harbouring strains caused a shift toward group D and B1 isolates ($P < 0.05$).

The frequencies of phylogroups were different than those reported previously for human, environmental and animal samples. Analysing integron-

Table 1 Distribution of genes coding for virulence factors and quinolone resistance among phylogenetic groups of *intI*-positive *E. coli* strains isolated from a wastewater treatment plant

Virulence factor gene	Virulence factor	Prevalence in phylogenetic groups				
		A (n = 33)	B1 (n = 21)	B2 (n = 15)	D (n = 40)	Total (n = 109)

<i>stx1, stx2</i>	Shiga toxin	3 (9.1%)	1 (4.8%)	2 (13.3%)	1 (4.8%)	7 (6.4%)
<i>fyuA</i>	Yersiniabactin	9 (27.3%)	3 (14.3%)	7 (46.7%)	10 (25%)	29 (26.6%)
<i>iutA*</i>	Aerobactin	10 (30.3%)	8 (38.0%)	10 (66.7%)	17 (52.5%)	45 (41.3%)
<i>hlyA</i>	Haemolysin A	1 (3.0%)	1 (4.8%)	1 (6.7%)	1 (2.5%)	4 (3.7%)
<i>papA</i>	P fimbriae	5 (15.2%)	3 (14.3%)	2 (13.3%)	8 (20.0%)	18 (16.5%)
<i>sfaS</i>	S fimbriae	9 (27.2%)	4 (19.0%)	2 (13.3%)	3 (7.5%)	18 (16.5%)
<i>focG</i>	F1C fimbriae	2 (6.1%)	2 (9.5%)	2 (13.3%)	4 (7.5%)	10 (9.2%)
<i>cnf1</i>	CNF	1 (3.0%)	1 (4.8%)	1 (6.7%)	2 (2.5%)	5 (4.6%)
VF score (mean)		0–4 (1.24)	0–4 (1.52)	0–5 (1.87)	0–4 (1.28)	0–5 (1.40)
Quinolone resistance		19 (57.6%)	13 (61.9%)	9 (60.0%)	20 (50.0%)	61 (56.0%)
Fluoroquinolone resistance		14 (42.2%)	9 (42.9%)	9 (60.0%)	23 (57.5%)	55 (50.4%)

* Statistically significant differences among phylogenetic groups ($P < 0.05$)

bearing intestinal *E. coli* isolates from healthy subjects without antibiotic exposure, Skurnik et al. (2005) have found phylogroup A as the most numerous (44.4%), followed by equal numbers of B1 and D (25.9%) and the least abundant group B2 (3.7%). In our research the *intI*-positive B2 strains were the least frequent as well, but their frequency was noticeably higher (13.8%).

When it comes to phylogrouping of *E. coli* strains isolated from wastewater without an a priori integron selection, the proportions were also different. Sabaté et al. (2008) have shown that phylogroup D was the least abundant in human wastewater isolates of *E. coli* (8%) and not frequent among chicken sewage strains (12%). Majority of the strains belonged to group A (52% of human and 51% of chicken wastewater strains), followed by B1 (20% of human and 5% of chicken wastewater strains) and B2 (20% of human and 33% of chicken wastewater strains). Our results are also in contrast to those observed in random environmental and animal samples of *E. coli* in the study of Higgins et al. (2007), in which phylogroup B1 was most abundant (31%), followed by A (26%), D (25%) and B2 (17%). Duriez et al. (2001) in an a set of 168 human commensal *E. coli* strains isolated from the stools of three geographically distinct human populations (France, Croatia, and Mali) have found phylogenetic groups A (40%) and B1 (34%) the most common, followed by group D (15%) and B2 (11%).

Members of group B2 and D possess the *chuA* gene—these groups are supposed to encompass most of pathogenic *E. coli* strains and in our research they made up 50.5% of *intI*-positive strains. It has been suggested that the protein coded by *chuA* is involved in human host colonization and thus can have impact on pathogenicity (Hoffmann et al. 2001). In our study, the frequency of *chuA* is higher than that reported by Hoffmann et al. (2001) for strains isolated from environmental samples (30%) and lower than those isolated from human sources (70%).

Diarrheagenic pathotypes of *E. coli*

Twenty-two strains (20.2%) were classified as diarrheagenic pathotypes: 12 ETEC strains, seven STEC and three EPEC. No EAEC and EIEC strains were found. Diarrheagenic *E. coli* were found mostly in B1 phylogenetic group (42.9%), but this was due to high number of ETEC isolates. All ETEC strains had only the heat-

stable toxin gene. It was identified in 33.3% of strains belonging to B1 group, and in groups D (three strains) and A (two strains). The presence of ST toxin gene was associated with the phylogenetic group affiliation ($P < 0.05$) (Table 1). Seven STEC isolates harboured *stx2* gene, one of them additionally had *stx1* gene. Shiga toxin genes *stx1* and *stx2* were present in 0.9 and 6.4% strains, respectively. The enteropathogenic *E. coli* isolates were determined as atypical EPEC, as they lacked *bfpA* gene encoding the bundle-forming pilus subunit. They belonged to groups B2, B1 and D. Atypical EPEC are considered less virulent than typical EPEC. Still, the strains can cause infection among children (Gomes et al. 2004) and both animals and humans can be their reservoirs (Trabulsi et al. 2002).

Distribution of virulence genes characteristic for ExPEC isolates

Genes *iutA* and *fyuA* coding for aerobactin and yersiniabactin receptor protein, respectively, are a part of siderophore-mediated systems of iron acquisition. Both aerobactin and yersiniabactin are recognized virulence factors in *Enterobacteriaceae*. The *iutA* gene was present in 41.3% of *E. coli* strains, whereas 26.6% possessed *fyuA* (Table 1). The *cnf1* gene located within PAI II and coding for cytotoxic necrotizing factor was found in five strains (4.6%) belonging to all four phylogroups. Haemolysin A gene, *hlyA*, associated with pathogenicity islands PAI I and II of uropathogenic *E. coli*, was present in four (3.7%) strains. P fimbriae subunit gene, *papA*, also embedded in pathogenicity islands, was observed in 18 strains (16.5%). Similarly, S fimbriae subunit gene, *sfaS*, located within PAI III, was found in 16.5% strains. Fimbrial F1C subunit gene, *focG*, was present in 9.2% of the strains.

Only presence of *iutA* was associated with phylogenetic group affiliation. It was significantly higher among isolates from group B2 (compared versus group A, B1, and groups A, B1 and D taken together). It was also higher among group D strains compared with those from group A and B1 ($P < 0.05$) (Table 1).

Antimicrobial susceptibility and distribution of quinolone resistance

All of the strains were multiresistant, i.e. resistant to three unrelated antimicrobials. The highest percent of

resistance was noted for sulfamethoxazole, ticarcillin, tetracycline and trimethoprim. The lowest frequencies of resistant strains were noted for imipenem, ceftazidime and netilmicin (Fig. 1).

Resistance to nalidixic acid was observed in 56% of *E. coli* strains; 50.4% were resistant to fluoroquinolones: ciprofloxacin or norfloxacin (Table 1). The distribution of Q (quinolone) and FQ (fluoroquinolones) resistance within phylogenetic groups was as follow: A: 69.7 and 42.4%, B1: 61.9 and 42.9%, B2: 60 and 60%, and D: 50 and 57.5%, respectively (Table 1). The resistance to quinolones and fluoroquinolones was not associated with phylogenetic group. The frequency of resistance to quinolones was higher in comparison with that reported by Sabaté et al. (2008) for *E. coli* strains from human wastewater, which were in 24% resistant to quinolones and in 20% to ciprofloxacin. None of their B2 strains has shown quinolone resistance, which is in contrast with the high frequency of Q and FQ resistance in B2 strains in our research.

Association of quinolone resistance with virulence genes

Although integron-positive strains are often multiresistant, only resistance to quinolones has been reported to be associated with decrease in pathogenic potential of *E. coli* strains (Kawamura-Sato et al. 2010). There is little information about virulence potential of integron-bearing *E. coli* isolated from wastewater. In our study, the average number of genes associated with diarrheagenic pathotypes and ExPEC per strain was low and reached 1.40. The highest average VF score was found in phylogroup B2 (1.87), whereas the lowest (1.24) was observed in group A; however, the differences in VF scores among phylogenetic groups were not statistically significant (Table 1). In clinical strains of *E. coli* causing bacteraemia it ranges from 1.9 to 4.5, depending on resistance profiles, and is lower in multiresistant strains (2.8) and in ciprofloxacin-resistant (1.9) (Rijavec et al. 2008). In our study, at low

Virulence gene	Virulence factor	Quinolone resistant 61 (56.0%)	Fluroquinolone resistant 55 (50.4%)	Susceptible 34 (31.2%)
<i>eae</i>	Intimin	1 (1.6%)	0	2 (5.9%)
ST gene	ST toxin	8 (13.1%)	9 (16.4%)	2 (5.9%)
<i>stx1, stx2</i>	Shiga toxin	2 (3.3%)	2 (3.6%)	4 (11.8%)
<i>fyuA</i>	Yersiniabactin	21 (34.4%)	15 (27.3%)	6 (17.6%)
<i>iutA</i>	Aerobactin	30 (49.2%)*	28 (50.1%)*	9 (26.5%)*
<i>hlyA</i>	Haemolysin A	2 (3.3%)	0	2 (5.9%)
<i>papA</i>	P fimbriae	10 (16.4%)	7 (12.8%)	6 (17.6%)
<i>sfaS</i>	S fimbriae	7 (11.5%)	4 (7.3%)*	9 (26.5%)*
<i>focG</i>	F1C fimbriae	7 (11.5%)	5 (9.1%)	2 (5.9%)
<i>cnfI</i>	CNF	3 (4.9%)	1 (1.8%)	1 (2.9%)
VF score (mean)		0–5 (1.53)	0–4 (1.30)	0–3 (1.24)

*Statistically significant differences ($P < 0.05$)

level of VF score, phenotypic resistance to quinolones and fluoroquinolones was not associated with VF score ($P > 0.05$). Nevertheless, we noticed significantly higher presence of *iutA* gene in quinolone and fluoroquinolone resistant isolates and lower presence of *sfaS* gene in fluoroquinolone resistant strains ($P < 0.05$) (Table 2).

In conclusion, integron-positive *E. coli* strains originating from wastewater treatment plant belong mostly to phylogenetic group D, usually connected with extraintestinal pathotypes. Although the average VF score was low, more than one-sixth of the multiresistant strains had three or more virulence genes. They were isolated mostly from raw sewage, but 30% of them were cultured from final effluent which is released to the corresponding river. This may create potential threat of spreading multiresistant, integron-bearing *E. coli* strains with virulence traits into the environment and be of public health concern. Moreover, some virulence genes are embedded in pathogenicity islands and together with potentially mobile resistance integrons located in plasmids they may be disseminated in the environment via horizontal gene transfer.
