Abstract

IspH is a 4Fe-4S protein that carries out an essential reduction step in isoprenoid biosynthesis. Using hyperfine sublevel correlation (HYSCORE) spectroscopy, we show that pyridine inhibitors of IspH directly bind to the unique $4th$ Fe in the 4Fe-4S cluster, opening up new routes to inhibitor design, of interest in the context of both anti-bacterial as well as anti-malarial drug discovery.

Keywords

Isoprenoid; non-mevalonate; IspH (LytB); inhibitors; HYSCORE

Isoprenoid biosynthesis is an important target for drug discovery.¹ In most pathogenic bacteria as well as in malaria parasites, the early stages in isoprenoid biosynthesis are carried out by the methylerythritol phosphate pathway.² This pathway is essential for producing the isoprenoids used in e.g. cell wall biosynthesis in bacteria, and in quinone formation and, since it is not present in humans, the enzymes involved are important targets for the development of new antibiotics.³ The last two enzymes, IspG and IspH, are unusual 4Fe-4Scontaining proteins that carry out $2H^+/2e^-$ reductions of the substrates MEcPP (2-C-methyl-D-erythritol-2,4-*cyclo* diphosphate, 1)⁴⁻⁶ and HMBPP (*E*-1-hydroxy-2-methyl-but-2-enyl-4diphosphate, 2) to form the C_5 isoprenoids IPP (isopentenyl diphosphate, 3) and DMAPP (dimethylallyl diphosphate, **4)** in an ∼1:5 ratio,7, 8 as shown in Scheme 1:

In recent work we proposed that both the IspG (EC 1.17.7.1, HMBPP synthase, also known as GcpE 9^9 as well as the IspH (EC 1.17.1.2, HMBPP reductase, also known as LytB) catalyzed reactions involve formation of organometallic species (i.e. containing Fe-C bonds).10 Support for the intermediacy of organometallic species in catalysis comes indirectly from electron paramagnetic resonance (EPR) and electron nuclear double resonance (ENDOR) spectroscopy as well as mechanistic considerations,10 and more directly, from the observation that the Fe-C distances $(2.6-2.7 \text{ Å})$ between the apical iron atom in the 4Fe-4S cluster and the allylic species seen crystallographically in IspH are even

shorter than the ones observed for bound $HMBPP$,¹¹ and are far shorter than the 3.6-3.7 Å sum of the Fe, C van der Waals radii.¹² We also found that alkynes could be quite potent inhibitors of both IspG and IspH, and that EPR and ENDOR spectra indicated that these alkynes bound at or very close to the unique $4th$ Fe in the reduced $4Fe$ -4S cluster. The ability to inhibit IspG or IspH is of interest in the context of the development of anti-infectives, and the ability of a given compound to inhibit both enzymes is of even more interest since, in principle, it will lead to a decrease in drug resistance since both enzymes would be required to mutate.

In addition to alkyne inhibitors, we discovered a second class of IspH inhibitors, pyridine diphosphates, 13 but how these bound to the protein was not clear. Here, we report the results of an X-band hyperfine sublevel correlation (HYSCORE) spectroscopic as well as a quantum chemical investigation, which helps clarify how these inhibitors function.

We first investigated a series of pyridine ligands, **5-11**, Scheme 2, binding to wild-type IspH from *Aquifex aeolicus*. The continuous-wave EPR spectrum of IspH + pyridine (**5**) is the same as that of the unliganded protein (i.e. in the absence of pyridine, Figure S1a), and there is no evidence for any sizeable pyridine-14N hyperfine interaction in the HYSCORE spectrum (Figure S1b), indicating only very weak binding affinity to IspH. The same results are obtained with the more basic ($pK_a = 6.8$ *vs.* 5.2) species 2-aminopyridine (**6**, Figure S1c). However, on addition of the inhibitor BPH-293 (7, $IC_{50} = 38 \mu M$), the EPR spectrum changes¹³ (Figure S1a) and new signals attributable to ¹⁴N single and double quantum transitions appear in the $(+,-)$ quadrant of the HYSCORE spectrum (Figure 1a). The ¹⁴N hyperfine interaction is quite large, with the hyperfine coupling constant being ∼8 MHz. Reconstituted IspH (Figure 1a) and anaerobically purified IspH (Figure S2) both give the same results. The *ortho* and *para*-pyridyl analogs of **7** (compounds **8**, IC₅₀ = 1.2 mM and **9**, IC₅₀ = 149 μM) show no evidence of any sizeable pyridine-¹⁴N hyperfine interaction in their HYSCORE spectra (Figure S1d, e), due presumably to their inability to bind to the $4th$ Fe, for "steric" reasons. Moreover, chlorine substitution of **7** (compound **10**) results in loss of all activity $(IC_{50} > 3$ mM), due presumably to loss in donor-ability of the pyridine nitrogen (the computed pK_a values of the pyridine fragments in 7 and 10 are 4.7 and 0.7, respectively), consistent with the absence of a pyridine-14N HYSCORE signal (Figure S1f). Addition of one CH₂ group to the side-chain of 7 results in a better inhibitor (11, IC₅₀ = 9.1 μ M), although there is no significant difference between the HYSCORE spectra of **7** (Figure 1a) and 11 (Figure S1g), indicating that differences in enzyme inhibition are due to differences in the alkyl diphosphate fragment binding in the active site, rather than differences in Fepyridine interactions.

These results do not, however, prove that the ^{14}N HYSCORE signals in the $(+,-)$ quadrant (Figure 1a and Figure S1g) arise directly from the inhibitors **7** and **11** since, in principle, inhibitor binding might result in a protein conformational change and binding of a protein ligand to Fe, e.g. the nearby His 42 or 124, which form part of the active site.¹⁴ To investigate this possibility, we prepared a sample using uniformly 15N-labeled IspH and inhibitor **7**. As can be seen in Figure 1b, the ¹⁴N signals centered at ∼3.6 MHz seen in Figure 1 are no longer present, and are replaced by a signal centered at 1.5 MHz, the ^{15}N Larmor frequency. Moreover, the ¹⁴N signals in the $(+,-)$ quadrant are essentially identical to those seen in samples prepared using unlabeled IspH (Figure 1a). This strongly suggests that the signals centered at ∼3.6 MHz arise from protein nitrogens near the 4Fe-4S cluster, while the ¹⁴N signals in the $(+,-)$ quadrant arise from the bound inhibitor **7**, rather than from any protein residues.

To begin to better understand the interaction between the pyridine inhibitor **7** and IspH, we next simulated the HYSCORE spectra of IspH + **7** taken at three different magnetic field

strengths (Supporting Information, Figures S3a, b and c) using the EasySpin program¹⁵ (Figures S3d, e and f), finding $a_{\text{iso}}(^{14}N) = 7.4 \text{ MHz}$, $A_{\text{ii}}(^{14}N) = [6.2 \text{ 7.6 \text{ 8.4}}] \text{ MHz}$ for the hyperfine interaction, and $e^2qQ/h = 3.0$ MHz for the nuclear quadrupole coupling constant.

This large a_{iso} ⁽¹⁴N) is similar to, or even larger than, that of a number of systems in which nitrogens directly bind to Fe centers. For example, in met-myoglobin the porphyrin nitrogens have $a_{\text{iso}} = 8.11 \text{ MHz}$ and 7.8 MHz, and the histidine N_ε has $a_{\text{iso}} = 9.28 \text{ MHz}$.¹⁶ In a model heme complex, FeTPP(4-MeIm)₂ (TPP, tetraphenylporphyrin; 4-MeIm, 4-methyl imidazole), the a_{iso} of the porphyrin nitrogens is 5.1 MHz, while that of the coordinated 4-MeIm is 5.7 MHz.17 In Rieske-type 2Fe-2S proteins, *a*iso(¹⁴N) of the coordinated His nitrogens are approximately 5 MHz,¹⁸ and in the case of the 4Fe-4S enzyme MoaA (which also has an unique $4th$ iron), N1 of the substrate guanosine 5'-triphosphate binds to the $4th$ iron and has a_{iso} (¹⁴N) = 3.6 MHz.¹⁹ On average, these results give an a_{iso} (¹⁴N) ~ 6 MHz for systems containing Fe-N bonds, suggesting that the $IspH + 7$ complex also contains an Fe-N bond.

The large $14N$ hyperfine interaction seen in the IspH $+7$ complex might also, at least in principle, indicate that the pyridine fragment is just close-by to the reduced 4Fe-4S cluster, without directly bonding to the 4th iron. For example, the pyridine group might be protonated and interact with e.g. the $E126 CO₂$ group that is close to the cluster; or it could be close-by, but deprotonated. Fortunately, determination of the ^{14}N nuclear quadrupole coupling constant (*e* ²*qQ/h*) enables an answer to this question, since protonated, neutral and metal-coordinated pyridine ligands have very different *e* ²*qQ/h* values.²⁰

For pyridine itself, the e^2qQ/h is 4.6 MHz, but in species in which there is a formal $+1$ charge on N, such as the pyridinium ion (**12**), pyridine-N-oxide (**13**) and N-methyl pyridinium (**14**), *e* ²*qQ/h* values of approximately 1 MHz are observed experimentally.20 In the case of pyridine bonded to Fe in Fe(CO)₄(pyr), **15**, e^2qQ/h is in between these extreme values ($e^2 qQ/h \sim 2.4$ MHz), and for Mo(pyr)₂(CO)₄ as well as Cr(CO)₄(2,2′-bipyridyl), *e*²*qQ*/h ∼3.1 MHz. So, when pyr is bonded to Cr, Mo or Fe, the *e*²*qQ*/h decreases from the 4.6 MHz seen in free pyridine to ∼ 2.4 – 3.1 MHz, due to metal-ligand bonding, close to the 3.0 MHz value we find from the 14N HYSCORE results.

To see to what extent these $e^2 qQ/h$ values might be reproduced computationally, we used the Gaussian-09 (Revision A.01) program.²¹ Results are given in Table S1 and are shown graphically in Figure 2 and Figure S4. Clearly, there is a good correlation (Figure 2a) between theory and experiment ($R^2 = 0.965$; slope = 0.963) for a series of model systems, and when using $[Fe_4S_4(SMe)_3(pyr)]^2$ (**16**, Figure 2b) as a model, we find $e^2qQ/h = 2.3$ MHz for the pyridine ¹⁴N, in quite good accord with experiment.

This large decrease in $e^2 qQ/h$, from the 4.6 MHz value found for free pyridine to the 2.4 – 3.1 MHz values observed in model systems and the IspH + **7** complex, is also seen in proteins in which imidazole (histidine) ligands bind to Fe. For example, for imidazole (**17**) the N3 (deprotonated) e^2qQ/h is 4.032 MHz,²² in good accord with the 3.894 MHz computed using DFT. The *e* ²*qQ/h* values for solid imidazole and solid histidine are both smaller and essentially identical (3.27 MHz, Im; 3.36 MHz, His)²³ – due presumably to very strong hydrogen bonding in the solid state. But when bound to Fe in metalloproteins, *e* ²*qQ/h* decreases considerably from the 4 MHz gas phase value (for imidazole).

For example, in myoglobins, e^2qQ/h ranges from 2.2 – 2.5 MHz for the directly bonded imidazole nitrogens;²⁴⁻²⁶ in the $(Cys)_3$ (His)₁ – coordinated [2Fe-2S] cluster in the human mito-NEET protein (18), $e^2qQ/h = (-)$ 2.47 MHz;²⁷ and in several $(Cys)_2(His)_2$ -coordinated [2Fe-2S] Rieske-type protein (19), e^2qQ/h values have been reported to be in the range $~2.2$ -2.9 MHz.²⁸⁻³⁰ Clearly then, the ¹⁴N nuclear quadrupole coupling constant decreases

from ∼4 MHz for the free (gas phase) imidazole to ∼2.5 MHz when bound to Fe, similar to the decrease in $e^2 qQ/h$ we find with pyr bound to Fe in the 4Fe-4S cluster of IspH.

These results all support the idea that the IspH pyridine inhibitors bind to IspH via a Lewis acid/base (Fe₄S₄ cluster/ligand) mechanism with the donor orbital occupancy (σ) decreasing from 2 (pyridine) to ~1.73,²⁰ and that the hyperfine coupling seen experimentally is due to this η ¹-bonding, rather than being due to a neutral pyr, or pyr-H⁺ ligand just being close to the 4Fe-4S cluster. This, in turn, suggests that stronger Lewis bases (such as imidazolecontaining ligands) may be more potent IspH inhibitors. These results also support the idea that other inhibitors, such as alkynes, $^{10, 13}$ as well as possible reaction intermediates (η^3 allyls), $^{10, 11}$ also act as Lewis bases, when interacting with the 4Fe-4S cluster in IspH.

Overall, these results are of interest for several reasons. First, we find evidence for an $\rm ^{14}N$ HYSCORE signal when the pyridine inhibitor **7** binds to IspH. Based on isotopic labeling, this signal is assigned to the pyridine ¹⁴N. Second, the experimental e^2qQ/h (from simulations of field-dependent HYSCORE) is 3 MHz. This is between the $e^2qQ/h = 4.6$ MHz found for pyridine itself and *e* ²*qQ/h* values of ∼1 MHz found in pyridinium salts and pyridine-N-oxide, 20 and is in fact within the 2.4 – 3.1 MHz range of values found for pyridines bound to Cr, Mo and Fe carbonyls.23 So, while the ligand may initially bind as the cationic species (to e.g. E126), the η^1 -complex is the more stable species. Third, we report the results of DFT calculations of the ¹⁴N nuclear quadrupole coupling constant (e^2qQ/h) in pyridine-containing metal systems finding a good correlation between theory and experiment ($R^2 = 0.965$, slope = 0.963, Figure 2), in addition to predicting a 2.3 MHz e^2qQ *h* value for a $[Fe_4S_4(SMe)_3(pyr)]^2$ model cluster, in quite good accord with experiment (given that the protein was excluded from the calculation, and the crystallographic structure of the 4Fe-4S/pyridine protein-containing complex is not yet known). When all published experimental results on pyridine and imidazole-containing systems are considered, there is a ∼35 – 40% decrease in the 14N *e* ²*qQ/h* on metal binding, the same as that found in the IspH + **7** system. This again supports formation of an η 1 -complex between IspH and **7**, an observation of interest in the context of the design of other inhibitors, of interest as antiinfective drug leads.
