### Abstract

**Aim**—The plant species reported here are traditionally used in Northern Peru for a wide range of illnesses. Most remedies are prepared as ethanol or aqueous extracts and then ingested. The aim of this study was to evaluate the potential toxicity of these extracts.

**Materials and methods**—The toxicity of ethanolic and water extracts of 341 plant species was determined using a Brine-Shrimp assay.

**Results**—Overall 24% of the species in water extract and 76% of the species in alcoholic extract showed elevated toxicity levels to brine-shrimp. Although in most cases multiple extracts of the same species showed very similar toxicity values, in some cases the toxicity of different extracts of the same species varied from non-toxic to highly toxic.

**Conclusions**—Traditional preparation methods take different toxicity levels in aqueous and ethanol extracts into account when choosing the appropriate solvent for the preparation of a remedy.

## 1. Introduction

In many developing countries, Traditional Medicine (TM) is commonly used as it is an accessible and affordable treatment (WHO, 1999a,b; 2002), while Complementary Alternative Medicine (CAM) is popular in developed countries (WHO, 1998; UNCCD 2000).

Peru is a prime example for a developing country rich in biodiversity, with a millennia old tradition of curers using the rich flora. Many of same plants are still being used nowadays. Northern Peru is believed to be the center of the Central Andean Health Axis (Camino, 1992), and TM practices in the whole Andean region are part of everyday life (Bussmann and Sharon, 2006; De Feo, 1992; Joralemon and Sharon, 1993; Polia, 1988; Revene et al., 2008). Peru's Social Security System recently implemented a National Program in Complementary Medicine in clinics and hospitals (EsSalud, 2000). The efficacy and potential toxicity of remedies employed in folk medicine do however have to be scientifically evaluated (Baker et al., 1995; Cox and Balick, 1994; Elisabetsky and Castilhos, 1990; Farnsworth et al., 1985; Muñoz and Sauvain, 2002).

A wide variety of studies have reported that some are bioactive (e.g. Perumal Samy and Ignacimuthu, 2000), but potentially active compounds have been isolated only from a few of the plants tested (D'Agostino et al., 1995a,b; Okuyama et al., 1994; Rodriguez et al. 1994; Umana and Castro, 1990). In contrast, crude medicinal activities have been investigated for a wide variety of plants (e.g. Bussmann et al., 2008, 2009a,b, 2010; Hammond et al., 1998, Lee et al., 1999; Neto et al., 2002; Villegas et al., 1997). But while toxicity assays are available for many countries (e.g. Argentina (Bustos et al., 1996; Hernández et al., 2000), Bahrain (Taha and Alsayed, 2000), Bangladesh (Costa-Lotufo et al., 2005), Brazil (Hammer and Johns, 1993; Alves et al., 2000; Holetz et al., 2002; Santos Piemanta et al., 2003; Quignard et al., 2004; Ferreira de Lima et al., 2006; Suffredini et al., 2006; dos Santos et al., 2007), Canada (McCuthcheon, 1992), Chile (Cuadra et al., 2005), China (Duffy and Power, 2001), Cuba (Martinez et al., 1996; Logarto Parra et al., 2001), Ecuador (Guerrero et al., 2003), Guatemala (Cáceres et al., 1993a, b, 1998; Michel et al., 2007), Honduras (Lenz et al., 1998), India (Padmaja et al., 2002), Kenya (Kirira et al. 2006; Wanyoike et al., 2004), Mexico (Sánchez-Medina et al., 2001), Nicaragua (Coe et al. 2010), Nigeria (Ajaiyeoba et al., 2006), Panama (Sánchez et al., 1993), Papua New Guinea (Nick et al., 1995), Philippines (Horgen et al., 2001), Uruguay (González et al., 1993), USA (Turker and Camper, 2002; Badisa et al., 2007; Van Slambrouck et al., 2007), no data exists on the potential toxicity of Peruvian medicinal species.

In this communication we report on brine-shrimp toxicity assays for 341 plant species ingested for a wide range of traditional uses. The brine shrimp, *Artemia* sp., Artemiidae, are small invertebrates occurring in sea-water and other saline ecosystems. *Artemia* is frequently used as agent in laboratory assays to determine toxicity values by estimating LC<sub>50</sub> values (median lethal concentration) (Meyer et al., 1982; McLaughlin et al., 1991; Cepleanu et al., 1994, Coe et al., 2010).

## 2. Materials and Methods

### 2.1. Plant Material

Plants for the presented assays were collected in Northern Peru (Fig. 1) in the field, in markets, and at the homes of traditional healers (*curanderos*) during March–April and June–August 2009, and January–February 2010. The specimens are registered under the collection series “JP”, “ACR,” “KMM,” and AKT”. Vouchers of all specimens were deposited at the

Herbarium Truxillense (HUT, Universidad Nacional de Trujillo), and Herbario Antenor Orrego (HAO, Universidad Privada Antenor Orrego, Trujillo). In recognition of Peru's rights under the Convention on Biological Diversity, most notably with regard to the conservation of genetic resources in the framework of a study treating medicinal plants, the identification of the plant material was conducted entirely in Peru. No plant material was exported in any form whatsoever.

## 2.2. Nomenclature

The nomenclature of plant families, genera, and species follows the Catalogue of the Flowering Plants and Gymnosperms of Peru (Brako and Zarucchi, 1993) and the *Catalogue of the Vascular Plants of Ecuador* (Jørgensen and León-Yanez, 1999). The nomenclature was compared to the TROPICOS database (Tropicos, 2010). Species were identified using the available volumes of the *Flora of Peru* (McBride, 1936–1981), as well as Jørgensen and Ulloa Ulloa (1994), Pestalozzi (1998) and Ulloa Ulloa and Jørgensen (1993), and the available volumes of the *Flora of Ecuador* (Sparre and Harling, 1978–2010), and reference material in the herbaria HUT and HAO.

## 2.3. Preparation of Extracts

For each species tested, above ground material (in case of trees leaves and) was collected, and the entire material used for extract preparation. This corroborates with the traditional preparation (Bussmann and Sharon 2006). Plant material was dried at 35 °C for three days. After drying, the material was ground with an industrial grinder, and 2 samples of 5 g. of plant material each were weighted out. One sample was submerged in 100 ml of 96 % ethanol and left to macerate for 7 days, while another sample was submerged in 100 ml of boiling distilled water and left to macerate for 24 h. After maceration the plant material was filtered and 100 ml 96 % ethanol was added to the water extracts to allow faster solvent removal. The solvent was then evaporated to complete dryness using a standard Buchi rotary-evaporator. The resulting dry extracts were re-suspended in 5 ml distilled water. In order to determine the real concentration of each extract, 1ml of previous homogenization of the respective extracts was removed and again completely oven-dried and then weighed to determine amount of extract per ml of final solution. The remaining extract was used for MIC assays.

## 2.4. Brine shrimp hatching

Eggs of brine shrimp (*Artemia* sp., Artemiidae) were purchased from Carolina Biological Supply (Burlington, NC, USA) and were incubated for 48 h in a culture vessel (15 × 15 × 15 cm) containing saltwater (1% NaCl) prepared from nitrate, phosphate, and silicate-free sea-salt and distilled water (35 g/l) at 25°C under constant illumination. The saltwater solution was aerated continuously during incubation with an aquarium air pump). After 48 h the Nauplius-larvae were collected from the culture vessel.

## 2.5. Brine shrimp lethality assay

The brine shrimp lethality assay (BSLA) was used to determine if the plant extracts of medicinal species were cytotoxic (Meyer et al., 1982; McLaughlin et al., 1991; Cepleanu et al., 1994, Coe et al., 2010). Plant extracts were diluted to concentrations of 1000; 500; 250; 125; 62.5; 31.25; 0 (µg/ml). Ten brine shrimp larvae were placed in each vial using a plastic pipette with a 2 mm diameter tip. The larvae were released under the surface of the solution to avoid killing them by trapping air under their carapaces. Survivors were counted under the stereomicroscope after 24 h, and the percent death at each dose and control was determined. All assays were run in triplicate. Vials with brine-shrimp in salt-water, and vials treated with 96 % Ethanol were used as controls.

## 2.6. Data analysis

The mean results of brine shrimp mortality were plotted against the logarithms of concentrations using the Probit Analysis tool of the NCSS statistical software package from which the median lethal concentration ( $LC_{50}$ ) at 95% confidence intervals (CI) were calculated according to the method of Finney (1971). Biological activity using the brine shrimp assay was recorded as the concentration when 50% of the larvae were killed within 24h of contact with the extract.  $LC_{50}$  values below 249 µg/ml were considered as highly toxic, 250–499 µg/ml as median toxicity and 500–1000 µg/ml as light toxicity. Values above 1000 µg/ml were regarded as non-toxic.

## 3. Results and Discussion

The Brine shrimp lethality activity of 501 aqueous and ethanolic extracts of 341 plant species belonging to 218 genera of 91 families used in Peruvian traditional medicine was tested. The results are shown in Tab. 1. The aqueous extracts of 55 species showed high toxicity values ( $LC_{50}$  below 249 µg/ml), 18 species showed median toxicity ( $LC_{50}$  250–499 µg/ml) and 18 low toxicity ( $LC_{50}$  500–1000 µg/ml). The alcoholic extracts proved to be much more toxic: 220 species showed high toxicity values ( $LC_{50}$  below 249 µg/ml, with 37 species having toxicity levels of >1µg/ml), 43 species showed median toxicity ( $LC_{50}$  250–499 µg/ml) and 23 species low toxicity ( $LC_{50}$  500–1000 µg/ml). Over 24% of the aqueous extracts and 76% of the alcoholic extracts showed elevated toxicity levels to brine-shrimp. Traditional preparation methods are taking this into account – most remedies are prepared as simple water extracts, thus avoiding potential toxic effects. Excellent examples where the water extracts are non-toxic, while the ethanolic extracts show high toxicity are *Ocimum basilicum* L., *Salvia* sp., or *Laccopetalum giganteum* (Wedd.) Ulbrich,. In contrast, *Cinchona officinalis* L. ethanolic extracts were nontoxic, and are traditionally used, while the highly toxic water extract has no traditional use.

Species which showed higher levels of toxicity were *Bejaria aestuans* L., *Erodium cicutarium* (L.) L'Her., *Brachyotum naudinii* Triana, *Miconia salicifolia* (Bonpl. ex Naud.) Naud., *Cuscuta foetida* Kunth, *Caesalpinia spinosa* (Molina) Kuntze, and *Phyllactis rigida* (Humb. and Bonpl.) Pers.. *Achillea millefolium* L., *Artemisia absinthium* L., and *Eucalyptus globulus* Labill all frequently used as medicinal teas also fall in this group, as do *Lupinus mutabilis* Sweet, and *Ilicium verum* Hook. f.. Solanaceae (e.g. *Nicotiana tabacum* L. and *Solanum americanum* Mill.) proved highly toxic, while other species, known to be highly toxic when ingested (e.g. *Datura* sp. and *Brugmansia* spp.) did not show toxicity in Brine Shrimp.

Multiple extracts from different collections of the same species showed in most cases very similar toxicity values. However, in some cases the toxicity of extracts from different collections of the same species varied from non-toxic to highly toxic. Examples for such variation in toxicity were found for *Chersodoma deltoidea* M.O. Dillon and Sagast., *Satureja sericea* (C. Presl. and Benth.) Briq., *Eugenia obtusifolia* Cambess., *Epidendrum* sp., *Capparis crotonoides* Kunth, *Sambucus peruviana* Kunth, and *Malva* sp. In case of these frequently used species, harvest time, collection locality or use of specific plant parts might be important for a reduction of toxicity.

## 4. Conclusions

Brine-shrimp bioassays offer a quick, simple and cost-efficient way of testing the toxicity of plant extracts, and allow a high throughput. This is of particular importance in developing countries where a large percentage of the population relies on the use of crude medicinal plant extracts to meet their health care needs, and where large numbers of different species

are used, often prepared in complex mixtures (WHO, 1998). The test does not necessarily constitute a direct link to toxicological effects in mammals (Sanchez et al., 1993), and should ideally be subjected to additional laboratory validation. However, it does give a good initial indication for the toxicity of the material tested.

Toxicity values with LC<sub>50</sub> values below 1000 µg/ml are considered to be bioactive and might provide leads for further screening (Meyer et al., 1982). Over 75% of the species in the present study might have some cytotoxic potential. The toxicity values reported fall in the range reported by other authors (e.g. Coe et al., 2010).

## Acknowledgments

The presented study was financed through MHIRT (Minority Health Disparity International Research and Training, Fund: 54112B MHIRT Program, Grant: G0000613), coordinated by San Diego State University (SDSU) in cooperation with the San Diego Museum of Man (SDMM), the P.A. Hearst Museum of Anthropology at the University of California Berkeley (PAHMAUCB), the Missouri Botanical Garden, USA, and the Universidad Privada Antenor Orrego (UPAO, Herbarium HAO), the Universidad Nacional de Trujillo (UNT, Herbarium HUT and Instituto de Medicina Tropical) and the Clínica Anticona Trujillo (CAT) in Peru.

None of the work would have been possible without the invaluable collaboration of our Peruvian colleagues, *curanderas* Julia Calderón, Isabel Chinguel, and Olinda Pintado, *curandero* Germán Santisteban, and herbalists Manuel Bejarano, Elmer Cruz, and Iván Cruz. With regard to ritual and therapeutic practices we especially want to thank the above *curanderas*, as well as *curandero* Leoncio Carrión.

Thanks also go to Eric Rodriguez (Herbarium Truxillense, HUT) and Abundio Sagastegui, Segundo Leiva, and Mario Zapata (Herbario Antenor Orrego, HAO) for the use of their facilities and their assistance in plant identification.

Most of all, we want to express our sincere gratitude to the people of Northern Peru for sharing their ethnobotanical knowledge.
