Abstract: Fexofenadine (FEX) has high solubility and low permeability (BCS, Class III). In this work, novel FEX loaded water in oil microemulsion (w/o) was designed to improve bioavailability and compared with Fexofen[®] syrup in in vitro and in vivo studies. In addition, pharmacokinetic parameters in permeability studies were estimated by using WinNonLin software program. w/o microemulsion system was optimized using a pseudoternary phase diagram, composed of span 80/lutrol F 68 (9.5:0.5 w/w), oleic acid, isopropyl alcohol and water as surfactant mixture; oil and cosurfactant was developed for oral drug delivery. w/o microemulsion systems were characterized by phase behavior, particle size, viscosity and solubilization capacity. In vitro studies were studied using Caco-2 cell monolayer. Pharmacokinetic parameters of w/o microemulsion were investigated in rabbits and compared to Fexofen[®] syrup. Fexofen[®] syrup and microemulsion were administered by oral gavage at 6 mg/kg of the same concentration. The experimental results indicated that microemulsion (HLB = 5.53) formed nanometer sized droplets (33.29 ± 1.76) and had good physical stability. This microemulsion increased the oral bioavailability of FEX which was highly water-soluble but fairly impermeable. The relative bioavailability of FEX microemulsion was about 376.76% compared with commercial syrup in rabbits. In vitro experiments were further employed for the enhanced effect of the microemulsion for FEX. These results suggest that novel w/o microemulsion plays an important role in enhancing oral bioavailability of low permeability drugs.

Keywords: pharmacokinetic, bioavailability, permeability, oleic acid

Introduction

Allergic rhinitis is a common disorder associated with a high incidence of morbidity.¹ Several mediators are involved in the pathophysiology of allergic diseases, so a variety of drugs, including antihistamines, decongestants, intranasal corticosteroids, leukotriene receptor antagonists, topical anticholinergics, mast cell stabilizers, mucolytics, and anti-IgE antibodies are used in the clinical treatment of allergic rhinitis. However, among these mediators, antihistamine remains the principal one, and plays a fundamental role in the genesis of allergic rhinitis. Therefore, antihistamines have been the main class of medications used for the treatment of allergic rhinitis over the past 60 years.^{2,3}

Fexofenadine hydrochloride, the active metabolite of terfenadine, a well known and effective H₁ receptor antagonist, is administered by the oral route. It is a non-sedating antihistamine providing rapid, long-acting, and highly selective peripheral H₁ receptor antagonist activity.⁴⁻⁶ The oral bioavailability of fexofenadine in humans is not established.⁷ However, in other animals, it is known to be as low as 4.2% (in rats)⁷ and 2.6% (in horses).⁸

In a review of 16 human pharmacokinetic studies, Chen et al reported that the half-life of fexofenadine varies between 3 and 17 hours.⁹ In our study, the half-life of fexofenadine w/o microemulsion was significantly ($P < 0.05$) decreased (by 2.04-fold) when compared with a commercial fexofenadine syrup (Fexofen[®], Sanovel, Istanbul, Turkey) because of differences in clearance rates and distribution volumes for the two formulations. In addition, the enterohepatic circulation is involved in the prolonged plasma elimination half-life of fexofenadine due to increased oral absorption.

The efflux transporter, P glycoprotein, has been reported to transport fexofenadine in in vitro models. Thus, it is considered to be an important determinant of the pharmacokinetics of fexofenadine.¹⁰ Fexofenadine is a substrate for P glycoprotein, and concomitant food and coadministration of drugs have significant effects on its oral bioavailability.¹¹ In addition, according to the biopharmaceutical classification system, fexofenadine belongs to the Class 3 drugs, which means it has high solubility and low permeability, so an effort to increase the permeability of fexofenadine is needed.¹²

Microemulsions known to enhance bioavailability in the gastrointestinal tract are thermodynamically stable, isotropically clear dispersions of two immiscible liquids, such as oil and water, and are stabilized by an interfacial film of surfactant molecules.^{13–17} Further advantages of using microemulsions as drug delivery systems include better drug solubilization and protection against enzymatic hydrolysis, as well as the potential for enhanced absorption due to a surfactant-induced increment in permeability. In addition, microemulsions represent an interesting and potentially quite powerful alternative carrier system for drug delivery because of their high solubilization capacity, transparency, ease of preparation, and high diffusion and absorption rates when compared with solvents without the surfactant system.^{18,19}

In this study, we designed and developed a novel microemulsion formulation to improve the oral absorption of fexofenadine. Absorption of fexofenadine in the intestine was compared with that of Fexofen syrup in vitro and in vivo in rabbits. In particular, Caco-2 cell permeability and the pharmacokinetics of the fexofenadine microemulsion were determined to evaluate the potential of the microemulsion to be an effective oral delivery carrier for drugs with bioavailability problems, like fexofenadine.

Materials and methods

Materials

Fexofenadine was provided by Basel Drug Company (Istanbul, Turkey). Diphenylhydramine was purchased from Sigma

Chemical Co (St Louis, MO). Lutrol F 68 was purchased from BASF (Ludwigshafen, Germany). Span 80, oleic acid, and isopropyl alcohol were obtained from Sigma-Aldrich (St Louis, MO). Cell culture reagents and supplies were obtained from Gibco Invitrogen (Grand Island, NY). Sodium dodecyl sulfate was purchased from Sigma Chemical Co.

Preparation of microemulsion

Solubility studies

The solubility of fexofenadine in various oils and surfactants was determined by adding an excess amount of fexofenadine into 1 mL of each vehicle, followed by shaking (100 rpm) at 25°C for 24 hours. The samples were centrifuged at 10000 rpm for 10 minutes to remove excess fexofenadine, and the concentration of fexofenadine in the supernatant was measured by high-performance liquid chromatography (HPLC) after appropriate dilution with isopropyl alcohol.

Construction of pseudoternary phase diagram

Microemulsion fields formed by dilution and gentle agitation were identified from ternary phase diagrams of systems containing oil-surfactant (S)-cosurfactant (coS). Oleic acid was selected as the oil phase. The effects of surfactants (mixtures of span 80 and lutrol F 68 at w/w ratios of 9.5:0.5 with a hydrophilic-lipophilic balance of 5.53) and the cosurfactant (isopropyl alcohol) on the pseudoternary phase diagram were systematically observed at room temperature. Lutrol F 68 were melted at 50°C–60°C and blended with span 80 to make the surfactant mixture. Afterwards, the oil phase and the surfactant mixture were mixed. The boundaries of the microemulsion domains were determined for different values of the S/coS (w/w) ratios. The S/coS weight ratios were 1:1, 2:1, 3:1, 4:1, and 5:1. Distilled water was added dropwise to each clear oil and surfactant mixture with gentle stirring to allow equilibration. Following addition of aliquots in the water phase, the mixture was examined visually for transparency. Based on the results of the pseudoternary phase diagrams, one microemulsion was selected for further experiments (Table 1). Thereafter, the fexofenadine-loaded microemulsion was prepared by adding 6 mg of fexofenadine per 1 mL of microemulsion with vortexing.

Characterization of microemulsion

Droplet size determination

The droplet size, polydispersity, and zeta potential of the microemulsions (with and without fexofenadine) were measured using a zeta sizer (3000 HS_A, Malvern Instruments, Worcestershire, UK) with six measurements.

Table 1 The solubility of FEX in various vehicles at 25°C

Vehicles	FEX (mg/mL)
Water	1.58 ± 0.04
Oil	
Oleic acid	6.15 ± 0.25
Surfactants	
Lutrol F 68	24.95 ± 0.49
Span 80	12.28 ± 0.04
Isopropyl alcohol	29.55 ± 0.27

Abbreviation: FEX, fexofenadine.

Viscosity

The viscosity of the microemulsions (with and without fexofenadine) was measured at 25°C ± 0.1°C using a Brookfield digital viscometer-III rheometer V 3.3 HB (Middleboro, MA) at 200 rpm (n = 6).

Conductivity measurements

The effect of the amount of water phase in the microemulsions was monitored quantitatively by measuring electrical conductivity. The water phase was added drop by drop into the mixture of oil phase and, after each drop of water, electrical conductivity was measured using a conductometer WPA CM 35 (Cambridge, UK), at 25°C ± 0.1°C. The conductivity of microemulsions with and without fexofenadine was measured (n = 6).

pH measurements

The pH values of the samples were measured by a pH meter (Jenway 3040 Ion Analyze, Combined Glass Electrode, Mettler-Toledo, Greifensee, Switzerland) at 25°C ± 0.1°C (n = 6).

HPLC analysis of fexofenadine

HPLC was used for the loading content and permeability studies of fexofenadine. Samples were appropriately diluted with isopropyl alcohol to 20 µL and injected directly into the HPLC system without further treatment. The HPLC system was equipped with a Waters 2487. A reverse phase C₁₈ column (250 mm × 4 mm, 5 µm) LiChroCART® (Merck, Darmstadt, Germany) was used at room temperature. The excitation and emission wavelengths of the fluorescence detector were set as 220 nm and 290 nm, respectively. A mixture of acetonitrile and 0.05 M pH 3.2 potassium dihydrogen phosphate buffer solutions (60:40, v/v) was used as the mobile phase at a flow rate of 1.0 mL/min.

Content of fexofenadine

Petroleum ether 2.5 mL was added to 200 mL of microemulsion containing fexofenadine and mixed for three minutes

at 1000 rpm, followed by addition of 2.5 mL 0.05 M pH 3.2 potassium dihydrogen phosphate buffer solution. The mixture was vortexed and centrifuged at 3000 rpm for 15 minutes. Finally, the upper liquid phase was constituted with 2.5 mL of mobile phase, and 20 µL was injected into the HPLC system (n = 6).

Stability test

To evaluate the stability of the optimized formulation of fexofenadine, the microemulsion was put into sealed glass vials, which were stored at 25°C and 40°C for 6 months. The clarity, concentration of fexofenadine, and droplet size were thereafter investigated at predetermined intervals (n = 6).

Permeability studies in Caco-2 cell monolayer

Cell cultures

The colonic adenocarcinoma cell line, Caco-2, was obtained from the American Type Culture Collection, and cultured in Dulbecco's Modified Eagle Medium. The cell monolayers were prepared by seeding 4 × 10⁵ cells/well on a 6-well Transwell® insert filter. Cell cultures were maintained at 37°C under 90% humidity and 5% CO₂. Monolayers were used 19–22 days after seeding. The integrity of each cell monolayer was checked by measuring its transepithelial electrical resistance (TEER) with an epithelial Volt-Ohm meter (EVOM, World Precision Instrument, Sarasota, FL) before and after the experiments (n = 6).

Permeability of fexofenadine from microemulsion versus syrup

The in vitro permeability study was developed in Caco-2 cell monolayers grown in Transwell inserts with collagen-coated polycarbonate membranes having a pore size of 0.4 µm and a surface area of 4.7 cm². The cells were maintained at 37°C in the atmospheric conditions described earlier. The medium was replaced every second day for 3 weeks. For the experiment with Caco-2 cell monolayers, w/o microemulsion (fexofenadine 6 mg/mL) and commercial syrup (6 mg/mL) formulations were diluted up to 95% (v/v) with Hank's Buffered Salt Solution (HBSS).

The permeability studies were performed in both directions, ie, from apical to basolateral and basolateral to apical. After washing the Caco-2 cell monolayer twice with prewarmed HBSS medium (pH 7.4), the fexofenadine microemulsion was diluted with HBSS (95% v/v). The transport experiments were done by adding the fexofenadine microemulsion diluted with HBSS to either the apical

(2.2 mL) or basolateral side (3.2 mL), while the receiving chamber contained the corresponding volume of transport medium. After shaking at 50 rpm for 2 hours at 37°C in a water bath, samples were collected from both sides of the Caco-2 cell monolayer and immediately stored below -20°C for subsequent HPLC analysis. The same procedure was used for the syrup formulation.

Apparent permeability values (P_{app}) for each side were calculated according to the following equation:

$$P_{app} = \frac{dQ}{dt} \frac{1}{ACo_0} \quad (1)$$

where P_{app} is the apparent permeability (cm/sec), dQ/dt is the permeation rate, A is the diffusion area of monolayers (cm^2), and Co is the initial concentration of drug in the donor compartment.¹

Pharmacokinetic studies in rabbits

Study design

Two groups of rabbits (weight 1.8–2.5 kg, provided by the Central Animal Laboratory of Ege University) were used to perform the in vivo pharmacokinetic study. Six rabbits were allocated to each group. All rabbits were maintained in a light-controlled room at a temperature of 25°C ± 0.5°C. The experimental protocols were approved by the Animal Care and Use Committee of the College of Pharmacy, Ege University. Before the experiment, the rabbits were fasted overnight for 12 hours with free access to water, and remained conscious throughout the experiment. For the oral administration, the fexofenadine syrup and w/o microemulsion formulations were administered at the same doses by oral gavage (6 mg/kg body weight). Blood samples (2 mL) were withdrawn from the ear vein at predetermined time intervals (hours 0, 1, 2, 3, 4, 5, 6, 7, and 8), and 75 µL/mL of heparin solution was used to maintain patency of the cannula between sampling times. Plasma samples were obtained by immediately centrifuging the blood samples at 10,000 rpm for 10 minutes, after which 500 µL of each plasma sample was stored at -20°C until analyzed by HPLC.

Plasma analysis

The fexofenadine concentration in the plasma samples was analyzed by HPLC.²⁰ Briefly, plasma samples (500 µL) were mixed with 2 µg/mL of internal standard (DFN) and 1500 µL of methanol. The mixture was vortexed for 10 minutes and centrifuged at 4000 rpm for 5 minutes at 5°C ± 0.5°C, and the supernatant was evaporated to dryness under nitrogen at 40°C. The residue was reconstituted with 200 µL of mobile

phase and injected into the HPLC system. Chromatography was performed using 3 µm C_{18} columns (100 mm × 3 mm, Phenomenex, Torrance, CA) at a flow rate of 0.8 mL/min with acetonitrile 0.02 M potassium dihydrogen phosphate buffer solution mixture (25:75, v/v) as the mobile phase at room temperature. A calibration curve was constructed in the range of 0.5–30 µg/mL. The mean correlation coefficient (r^2) for the calibration curve was at least 0.999.

Pharmacokinetic analysis

The pharmacokinetic parameters for fexofenadine after administration of the microemulsion and syrup were calculated for each rabbit using the WinNonlin® program (Version 3.1, Pharsight Co, Mountainview, CA). Noncompartmental analysis was used to calculate the peak plasma concentration, time taken to reach peak concentration, and the area under the curve (AUC). The relative bioavailability of the oral drug delivery system was calculated as follows:

$$\text{Relative bioavailability} = \frac{(AUC)_{\text{microemulsion}}}{(AUC)_{\text{syrup}}} \times 100 \quad (2)$$

Statistical analysis

A two-tailed unpaired Student's *t*-test was performed, with $P < 0.05$ considered to be statistically significant.

Results

Solubility studies

The solubility of fexofenadine in the various vehicles is shown in Table 1. Isopropyl alcohol was selected as a cosurfactant for the study because it has the highest solubility for fexofenadine and has been reported to have a favorable enhancing effect on the oral bioavailability of fexofenadine.⁹ Oleic acid was chosen as the oily phase for its good drug solubility (Table 1). Span 80 and Iutrol F 68 were selected as surfactants due to their ability to augment drug solubilization.⁷

Construction of pseudoternary phase diagrams

Investigation of the phase behavior of these systems demonstrated that our approach was suitable for determining the water phase, oil phase, surfactant concentration, and cosurfactant concentration at which the transparent phase microemulsion system was formed.²¹ The construction of a phase diagram makes it easy to identify the concentration range of components in the microemulsions. Figure 1 shows the

Figure 1 Pseudoternary phase diagrams of microemulsion system. (A) 1:1 S/coS ratio, (B) 2:1 S/coS ratio, (C) 3:1 S/coS ratio, (D) 4:1 S/coS ratio, (E) 5:1 S/coS ratio.

phase diagrams constructed to determine the optimum S/coS concentration ratio for the formulation of w/o microemulsion consisting of span 80, lutrol F 68, oleic acid, isopropyl alcohol, and water. The S/coS and surfactant mixture (span 80/lutrol F 68) ratios were found to be 1:1 and 9.5:0.5 for the optimized microemulsion. As shown in Figure 1A, the area of w/o microemulsion becomes enlarged and is highest at a S/coS ratio of 1:1. The exact composition according to oil, surfactant, cosurfactant, and aqueous phases is shown in Table 2.

Characterization of microemulsion

The physicochemical characteristics of the microemulsions are shown in Table 3. Particle size analysis showed that the mean droplet size for the microemulsions with and without fexofenadine was below 100 nm. Microemulsions without fexofenadine were transparent colloidal dispersions with an average diameter of 39.05 nm and a polydispersity index of 0.044. When fexofenadine was loaded into the microemulsion system, the microemulsion did not change in transparency or polydispersity index value, but the mean droplet size decreased from 39.05 nm to 33.29 nm. A possible

reason for this might be that the contents of the microemulsion and fexofenadine affect each other. When the fexofenadine molecule is dissolved and dispersed into the emulsifying membrane layer (composed of surfactant and cosurfactant) and oil phase, the chemical groups in the fexofenadine molecule can react with the other groups in the surfactant, cosurfactant, and oil phase, producing hydrogen bonds. This could be due to the decreased surface tension created by the presence of surfactant and cosurfactant.²² In addition, the zeta potential was measured. When fexofenadine was loaded to the microemulsion system, the zeta potential of the microemulsion increased from 1.95 mV to 2 mV. This increment was not statistically significant ($P < 0.05$). It is clear from the physicochemical data (Table 3) that microemulsions with and without fexofenadine had similar values for viscosity, conductivity, and pH ($P > 0.05$).

Fexofenadine content

Table 3 shows that the fexofenadine content in the microemulsion system was approximately 5.98 mg/mL. Loading of fexofenadine into the w/o microemulsion system was obtained, with an encapsulation efficiency of 99.67%.

Stability test

After storage at 25°C and 40°C for 6 months, the optimized fexofenadine microemulsion remained clear and transparent

Table 2 The contents of optimized microemulsion formulation

Formulation	Oil (%)	S ₁ (%)	S ₂ (%)	coS (%)	Water (%)
Microemulsion	34.05	1.49	28.31	29.79	6.36

Notes: S₁: Lutrol F 68, S₂: Span 80, coS: Isopropyl alcohol.

Table 3 Characterization of microemulsion

Samples	Electrical conductivity ($\mu\text{s cm}^{-1}$)	Viscosity η (cps)	Droplet size (nm)	Polydispersity	Zeta potential (mV)	Content of FEX mg/mL

B	1.1 \pm 0.02	103.8 \pm 0.25	33.29 \pm 1.76	0.044 \pm 0.02	-2.13 \pm 0.21	5.98 \pm 0.17

Notes: A: Microemulsion without FEX, B: Microemulsion with FEX.

Abbreviation: FEX, fexofenadine.

without any phase separation. Table 4 shows that the fexofenadine concentration and droplet size in the microemulsion was not changed significantly, suggesting that the fexofenadine-loaded microemulsion was stable under the above conditions.

Permeability of fexofenadine in Caco-2 cell monolayer

Figure 2 shows the permeability profiles for fexofenadine from the w/o microemulsion and from the commercial syrup across the Caco-2 cell monolayers. The permeability studies were performed at 37°C. The results indicate that permeability of fexofenadine from the w/o microemulsion was greater than that of the syrup formulation. The bidirectional P_{app} values for both formulations are summarized in Table 5.

Generally, substances with an apparent permeability coefficient (P_{app}) $< 1 \times 10^{-6}$ cm/sec are classified as low permeability substances, and those with an apparent permeability coefficient $> 1 \times 10^{-5}$ cm/sec are classified as high permeability substances.⁷ The microemulsion and commercial syrup formulations had high permeability for both directions. $P_{app B to A}$ (permeability from basolateral to apical direction) was higher than $P_{app A to B}$ (permeability from apical to basolateral direction)

Table 4 Stability of optimum microemulsion containing FEX (A) and (B)

Temperature/ month	25°C		40°C	
	Droplet size (nm)	Content of FEX (mg/mL)	Droplet size (nm)	Content of FEX (mg/mL)
(A)				
0	33.29 \pm 0.95	5.98 \pm 0.17	33.29 \pm 0.95	5.98 \pm 0.17
3	33.72 \pm 0.61	5.89 \pm 0.24	34.01 \pm 0.55	6.11 \pm 0.12
6	33.34 \pm 0.44	6.01 \pm 0.16	34.72 \pm 0.85	6.09 \pm 0.35
(B)				
	25°C		40°C	
	Zeta potential (mV)		Zeta potential (mV)	
0	2.13 \pm 0.21		2.13 \pm 0.21	
3	2.1 \pm 0.14		2.11 \pm 0.2	
6	2.01 \pm 0.09		2.14 \pm 0.15	

Abbreviation: FEX, fexofenadine.

for both formulations, consistent with the contribution of a secretion transporter, and fexofenadine has been demonstrated to be a *P* glycoprotein substrate.⁸ When the fexofenadine microemulsion was applied to the Caco-2 cell, the $P_{app A to B}$ was increased ($2.55 \times 10^{-5} \pm 0.05$ cm/sec) compared with the $P_{app A to B}$ of the syrup ($1.97 \times 10^{-5} \pm 1.23$ cm/sec), and the $P_{app B to A}$ was increased ($2.61 \times 10^{-5} \pm 1.77$ cm/sec) compared with the $P_{app B to A}$ of the syrup ($2.39 \times 10^{-5} \pm 1.33$ cm/sec). These findings suggest that fexofenadine in the microemulsion has higher permeability than when in the commercial syrup form. This also indicates that the microemulsion is an enhancer of fexofenadine permeability.

Effect of fexofenadine on TEER across Caco-2 cell monolayer

TEER values across Caco-2 cells have been used as indicators of tight junction integrity in cell monolayers. Therefore, the effects of both formulations on the ability to modulate tight junctions could be monitored using this indicator. Experiments performed with the commercial syrup showed a change in TEER of $< 20\%$ for 2 hours in both directions (apical to basolateral and basolateral to apical). However, experiments with the microemulsion showed a reduction in TEER over the 2 hours, with TEER being 33.7% and 41.1% of control values at 2 hours in the apical to basolateral and basolateral to apical directions, respectively (Table 6). Changes in TEER after treatment with the microemulsion were statistically significant compared with the commercial syrup ($P < 0.05$). In general, the microemulsion-induced decrease in TEER was correlated with an increase in permeability of fexofenadine.

Estimation of fexofenadine transport parameters

Fexofenadine permeability values for the microemulsion were higher than for the syrup in the basolateral to apical and apical to basolateral directions. This is consistent with the presence of surfactant and cosurfactant as permeability enhancers. The following model equations, including the passive diffusion component and the Michelis–Menten component, were fitted to the dataset for apical to basolateral

Figure 2 The amount of FEX permeability across Caco-2 cell ($n = 6 \pm SD$).

Notes: A to B for SY = The amount of FEX from apical to basolateral direction of syrup, B to A for SY = The amount of FEX from basolateral to apical direction of syrup, A to B for ME = The amount of FEX from apical to basolateral direction of microemulsion, B to A for ME = The amount of FEX from basolateral to apical direction of microemulsion.

Abbreviations: A, apical; B, basolateral; FEX, fexofenadine; ME, microemulsion; SD, standard deviation; SY, syrup.

and basolateral to apical permeabilities in order to estimate the passive component and V_m and K_m .

$$P_{\text{eff}} = P_{\text{dif}} - \frac{V_m}{K_m + C} \quad (3)$$

$$P_{\text{eff}} = P_{\text{dif}} + \frac{V_m}{K_m + C} \quad (4)$$

where P_{eff} is the experimental permeability value, P_{dif} is the passive diffusion component, and V_m and K_m are the Michaelis–Menten parameters. A second model was explored with the following equations:

$$P_{\text{eff}} = P_{\text{dif}} - \frac{V_m}{K_m + C} \quad (5)$$

$$P_{\text{eff}} = P_{\text{dif}} + \frac{V_m}{A * K_m + C} \quad (6)$$

in which A is a correction factor included to take into account the fact that the binding site of the secretion carrier is located inside the cells so it actually “sees” a different formulation than the donor chamber one. This factor helps to explain why permeability versus concentration is not symmetrical around P_{dif} in both directions. The change in apparent permeability is more evident in the basal to apical direction because the basolateral membrane has lower resistance, and when the

drug is applied in the basolateral chamber, the extracellular and intracellular concentrations are more similar than when the drug is placed in the apical chamber.²³ The parameters obtained with both kinetic models for the commercial syrup and microemulsion are summarized in Table 7. In order to compare the two models, the sum of squared residuals and Akaike information criterion values were tabulated.

The residual variances from both fits (sum of squared/degrees of freedom) were compared using the Snedecor’s F test and an alpha value of 0.05 with the following equation:

$$F_{\text{calc}} = \frac{(SSR_1 - SSR_2)/(df_1 - df_2)}{SSR_2 / df_2} \quad (7)$$

where SSR_1 is the sum of the squared residual of the simplest models and SSR_2 is the sum of the squared residuals of the more complex model, and df are the degrees of freedom of the fit (number of data points minus number of parameter estimated). The calculated F was higher than the tabulated F , indicating statistical significance of the more complex model, so the inclusion of parameter A improves the fit to the experimental data.

Pharmacokinetic studies in rabbits

and the syrup to rabbits, each at a dose of 6 mg/kg body weight ($n = 6$). Table 8 shows the pharmacokinetic parameters for fexofenadine that were evaluated by the noncompartmental method using the oral WinNonLin program. In this study, oral administration of w/o microemulsion in lower doses gave significantly higher peak plasma concentrations and AUC values compared with the syrup. The mean peak fexofenadine concentration in the group treated with the syrup was $1.97 \mu\text{g}/\text{m}$; a higher mean peak value of $18.63 \mu\text{g}/\text{mL}$ was obtained in the group treated with the microemulsion. This difference was statistically significant ($P < 0.05$). In the case of oral administration, the mean residence time and time to peak plasma concentrations obtained from the w/o microemulsion were significantly prolonged ($P < 0.05$) when compared with those for the syrup.

There have been many previous attempts at estimating the absolute oral bioavailability of fexofenadine, with values ranging widely from 10% to 90%.²⁴ For example, Chen found that the absolute bioavailability of fexofenadine was 35%.⁹ In this study, the relative bioavailability related to the $\text{AUC}_{0 \rightarrow 8}$ of fexofenadine was found to be 376.76% in w/o microemulsion compared with the syrup. This may be because the microemulsion allows the drug to be retained

Figure 3 Comparison of the plasma concentration values obtained after administration of FEX loaded microemulsion and Fexofen®syrup.

Abbreviation: FEX, fexofenadine; w/o, water in oil.

long enough in the gastrointestinal system to be well permeated in the gastrointestinal mucosa. According to the relative bioavailability value, the amount of fexofenadine in the microemulsion can be reduced, enabling a lower-dose formulation. Furthermore, a higher relative bioavailability, delayed mean residence time, and extended time to peak concentration with the fexofenadine microemulsion suggested that this microemulsion could have extended-release characteristics, and might be useful for extended-release oral formulations of fexofenadine.

Discussion

The minimum absolute oral bioavailability of fexofenadine in this study was 10%–15%, based on the amount of unchanged drug appearing in the urine.⁹ Extrapolation from animal data is unreliable, with oral bioavailability being 2%–4% in rodents²⁵ and only marginally higher at 6.6% in monkeys.²⁶ An estimate of 30% bioavailability in man has been made

based on two observations,⁹ one being the 10% recovery in urine after oral fexofenadine and the other the finding that fexofenadine is formed by the metabolism of orally administered terfenadine (which is rapidly and extensively metabolized), and is assumed to occur systemically.

To improve its oral bioavailability, some absorption enhancers can be used to improve the oral absorption of fexofenadine, such as chitosan, sodium deoxycholate, and sodium dodecyl sulfate.²⁷ However, these enhancers can lead to irritation of the intestinal tract, resulting in substantial damage to the intestinal mucosa.²⁸ Thus, it is hoped that a suitable pharmaceutical formulation of fexofenadine can be developed to improve intestinal absorption without damaging the intestinal tissue. Our w/o microemulsion system with surfactant and cosurfactant has the ability to form microemulsions, with good biological acceptance, which is the main reason for their use.²⁹ Water-soluble drugs are solubilized in w/o microemulsion and incorporated mainly in the water-phase core and therefore are released rather slowly.³⁰ In this study, the viscosity, refractive index, particle size, zeta potential, and electric conductivity of the microemulsion were investigated. The results demonstrated successful formation of a w/o microemulsion containing oil, surfactant/cosurfactant, and an aqueous phase. The optimal w/o microemulsion, consisting of oleic acid, lutrol F-68, span 80, and isopropyl alcohol, is a promising formulation for increasing absorption of fexofenadine by the oral route and could also increase the oral bioavailability of other drugs with low permeability. There are several barriers to the oral delivery of such drugs, including luminal enzymatic hydrolysis, low solubility, and low membrane permeability.^{31,32} Fexofenadine has good stability against enzymatic hydrolysis and at different pH values.³³ For fexofenadine, low membrane permeability is the main barrier to its oral absorption. However, because of its good solubility, significantly improved absorption and bioavailability was found for fexofenadine after oral administration of the w/o microemulsion than with the commercial syrup formulation in rabbits.

Conclusion

A novel fexofenadine-loaded microemulsion was designed to improve the oral absorption of fexofenadine.

The microemulsion system for fexofenadine was developed by construction of a pseudoternary phase diagram. The optimal formulation was as follows: 34.05% oil (oleic acid), 30% surfactant (span 80/lutrol F 68), 29.79% cosurfactant (isopropyl alcohol), and 6.16% distilled water. The optimized microemulsion was characterized according to viscosity, solubility, content of fexofenadine, conductivity, polydispersity, droplet size, and stability. In vitro and in vivo studies in Caco-2 cells and in rabbits showed that the microemulsion had significantly improved permeability across Caco-2 cells, a higher peak concentration and AUC, and shorter elimination half-life compared with the commercial syrup. Overall, the results indicate that the microemulsion was effective for enhancing the oral absorption of fexofenadine, and fexofenadine-loaded microemulsion demonstrates great potential for clinical application.
