Submitted June 5, 1989

EMBL accession no. X15363

A major focus of work on malaria vaccine development is to produce a vaccine that induces a protective T cell-mediated immune response against the circumsporozoite protein (CSP) of *Plasmodium falciparum*. Sequence analysis of the gene encoding the CSP in various uncloned strains of *P. falciparum* has revealed variation in putative T cell regions (1,2,3). Immunization/challenge studies conducted with cloned parasites will minimize the potential ambiguity associated with using uncloned lines. We have cloned and sequenced the gene encoding the CSP from the 3D-7 parasite clone derived from the NF54 strain of *P. falciparum*. Oligonucleotide primers homologous to the first and last 18 bases of the CSP gene of another line of *P. falciparum*, 7G8 (1), were synthesized with 5'-Eco RI linkers and used to specifically amplify the CSP gene of 3D-7 by the polymerase chain reaction. The amplified product was ligated into M13mp18 and sequenced in both directions. The complete nucleotide sequence of the gene is shown below.
