The present study investigated whether kisspeptin-G protein-coupled receptor 54 (GPR54) signaling plays a role in mediating mating-induced ovulation in the musk shrew (*Suncus murinus*), a reflex ovulator. For this purpose, we cloned *suncus Kiss1* and *Gpr54* cDNA from the hypothalamus and found that *suncus* kisspeptin (sKp) consists of 29 amino acid residues (sKp-29). Injection of exogenous sKp-29 mimicked the mating stimulus to induce follicular maturation and ovulation. Administration of several kisspeptins and GPR54 agonists also induced presumed ovulation in a dose-dependent manner, and *Gpr54* mRNA was distributed in the hypothalamus, showing that kisspeptins induce ovulation through binding to GPR54. The sKp-29-induced ovulation was blocked completely by pretreatment with a gonadotropin-releasing hormone (GnRH) antagonist, suggesting that kisspeptin activates GnRH neurons to induce ovulation in the musk shrew. In addition, *in situ* hybridization revealed that *Kiss1*-expressing cells are located in the medial preoptic area (POA) and arcuate nucleus in the musk shrew hypothalamus. The number of *Kiss1*-expressing cells in the POA or arcuate nucleus was up-regulated or down-regulated by estradiol, suggesting that kisspeptin neurons in these regions were the targets of the estrogen feedback action. Finally, mating stimulus largely induced *c-Fos* expression in *Kiss1*-positive cells in the POA, indicating that the mating stimulus activates POA kisspeptin neurons to induce ovulation. Taken together, these results indicate that kisspeptin-GPR54 signaling plays a role in the induction of ovulation in the musk shrew, a reflex ovulator, as it does in spontaneous ovulators.

brain | copulation | Kiss1r | metastin | ovary

Mammals have two major repertoires in their ovulatory mechanism: spontaneous ovulation and reflex ovulation. In the spontaneous ovulator, estrogen surge is a key regulator to induce a gonadotropin-releasing hormone (GnRH)/luteinizing hormone (LH) surge leading to ovulation (1). In this case, the brain's detection of an increase in circulating estrogen secreted from the mature follicles triggers ovulation. The reflex ovulator, on the other hand, has a characteristic that is unique in the ovulatory mechanism: The mating stimulus is a dominant factor inducing ovulation. The reflex ovulator lacks behavioral and ovarian estrous cycles. Interestingly, spontaneous ovulators may have an inherent mechanism mediating mating-induced ovulation, because rats are known to show reflex ovulation when maintained in a constant-light condition (2, 3). It has been suggested that coitus-induced ovulation even occurs in women (4). Thus, from the evolutionary aspect, every mammalian species may have an innate mechanism for reflex ovulation that is likely a more ancient form of reproduction than spontaneous ovulation.

The musk shrew (*Suncus murinus*), a reflex ovulator (5, 6) and a member of the order Insectivora, is considered the most primitive of placental mammals (7). In this animal, the mating stimulus induces formation of a follicular cavity and then ovulation (5). The musk shrew, therefore, is a unique animal model for investigating the neuroendocrine mechanism mediating

ovulation, because the mating stimulus is an external trigger activating GnRH neurons to induce ovulation (8). The neuroendocrine pathway involved in the mating-induced ovulation in the musk shrew is not yet fully understood.

Kisspeptin, a *Kiss1* gene product, has been identified as an endogenous ligand of G protein-coupled receptor 54 (GPR54) (9, 10). Accumulating evidence suggests that in many mammalian species the kisspeptin-GPR54 system plays a critical role in inducing gonadotropin secretion through stimulation of GnRH release (11–17). Kisspeptin neurons play a role in the generation of the surge mode of GnRH/LH release to mediate the estrogen-positive feedback effect and then ovulation (18–21) as well as the pulsatile GnRH/LH release responsible for follicular maturation (22, 23). Thus, kisspeptin may mediate mating-induced ovulation through GnRH/LH release in the musk shrew.

The present study aimed to identify *suncus* kisspeptin and then to investigate whether the mating stimulus induces ovulation through activation of kisspeptin neurons in the musk shrew brain. First, we identified *Kiss1* and *Gpr54* genes, and then we tested whether deduced *suncus* kisspeptin and various other kisspeptins mimicked mating to induce ovulation. The distribution of *Kiss1* mRNA and the effect of estradiol on the *Kiss1* expression were determined in the musk shrew brain. Finally, we examined whether the mating stimulus induces *c-Fos* expression in *Kiss1*-expressing cells to determine whether this stimulus subsequently activates kisspeptin neurons to induce ovulation in the musk shrew.

Results

Characterization of *Suncus Kiss1* and *Gpr54* cDNA and Their Expression in Various Tissues. Nucleotide sequencing revealed that *suncus Kiss1* cDNA is 696 bp, and the ORF consists of 402 bp encoding a 133-amino acid polypeptide (Fig. 1A). The ORF of *Kiss1* cDNA is considered the kisspeptin precursor. Comparison of the overall amino acid sequence of the kisspeptin precursor revealed that the *suncus* kisspeptin precursor exhibits 43.6%, 43.6%, and 45.1% similarity to those of human, rat, and mouse, respectively. The position of the dibasic sequence of *suncus* kisspeptin precursor, which is predicted to be cleaved by a subtilisin-like proprotein convertase, is different from that in other species reported. The

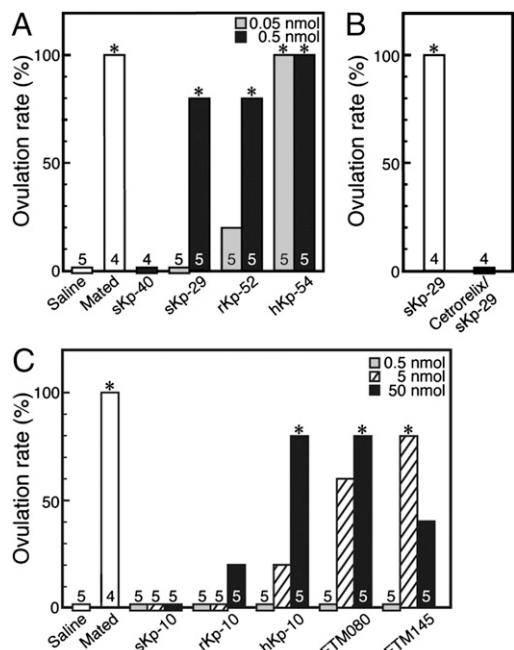

Fig. 3. Effects of various kisspeptins and GPR54 agonists on the ovulation rate. (A) The ovulation rate in musk shrews that were mated or injected with saline or sKp-40 (0.5 nmol per animal) or with sKp-29, rKp-52, or hKp-54 (0.05 or 0.5 nmol per animal). * $P < 0.05$ (Fisher's exact test). (B) Effect of cetrorelix, a GnRH antagonist, on sKp-29-induced ovulation. * $P < 0.05$ (Fisher's exact test). (C) The ovulation rate in musk shrews that were mated or were injected with saline, sKp-10, rKp-10, hKp-10, or the GPR54 agonists FTM080 or FTM145 (0.5, 5, or 50 nmol per animal). * $P < 0.05$ (Fisher's exact test). Numbers over each column indicate the number of animals treated.

highest dose (50 nmol). The GPR54 agonists FTM080 and FTM145 also induced presumed ovulation effectively (Fig. 3C).

sKp-29 Challenge Mimics the Mating Stimulus to Induce Follicular Development and Corpus Luteum Formation. Saline-treated control animals had no mature follicles or corpus luteum (Fig. 4A and B). sKp-29 challenge induced the slit-like follicular cavity and then corpora lutea formations 10 h and 3 d after treatment, respectively (Fig. 4E and F). Similar formation of a follicular cavity and then corpora lutea was found at 10 h and 3 d, respectively, after the onset of mating (Fig. 4C and D). sKp-10 did not cause any obvious morphological changes in ovaries (Fig. 4G and H).

Distribution of *Kiss1* mRNA and the Effect of Estradiol on *Kiss1* Expression in the Suncus Hypothalamus. *Kiss1* mRNA expression was found in the medial preoptic area (POA) and arcuate nucleus (ARC) in the suncus brain (Fig. 5A–F). *Kiss1* mRNA expression in the POA was slightly higher in intact and estradiol-treated ovariectomized (OVX+E) animals than in ovariectomized (OVX) animals (Fig. 5A–C). *Kiss1*-expressing cells in the ARC were more abundant in OVX animals however, whereas *Kiss1* signals in the ARC were quite weak in intact and OVX+E animals (Fig. 5D–F).

Activation of Kisspeptin Neurons by Mating Stimulus. c-Fos immunoreactivity was found in few *Kiss1*-expressing cells in the POA of female suncus without mating (Fig. 6A), but c-Fos was highly expressed in *Kiss1*-expressing cells in the POA after mating. The percentage of POA *Kiss1* cells coexpressing c-Fos was significantly higher in mated females ($P < 0.05$, student's *t* test) than in nonmated controls (Fig. 6B). The total number of *Kiss1*-expressing cells in the POA also was significantly higher in mated animals than in nonmated animals. In the ARC, *Kiss1* and c-Fos

Fig. 4. Effects of sKp-29 and sKp-10 on follicular development and corpus luteum formation. Photomicrographs of ovaries with H&E staining in animals that were mated (C and D) or injected with saline (A and B), sKp-29 (E and F), or sKp-10 (G and H). Photographs were taken 10 h (A, C, E, and G) or 3 d (B, D, F, and H) after the onset of mating or injection. Mated and sKp-29-injected shrews showed slit-like follicular cavity (arrowheads) in ovarian follicles at 10 h and fungiform corpora lutea in the ovary at 3 d. Insets show the boxed area in each panel at higher magnification. AF, atretic follicle; CL, corpus luteum; EGL, extra granulosa layer; FC, follicular cavity; IGL, inner granulosa layer; MF, mature follicle; PF, premature follicle; SF, secondary follicle. (Scale bars: 100 μ m.)

expression was low even after mating; there was no significant difference between mated and nonmated females in the total number of *Kiss1*-expressing cells in the ARC or in the percentage of *Kiss1* cells in the ARC coexpressing c-Fos (Fig. 6B).

Discussion

The musk shrew is a useful animal model for investigating the role of kisspeptin–GPR54 signaling in the induction of ovulation, because the shrew is a reflex ovulator and has maturing (but not mature) follicles that are ready to ovulate when the animal receives the mating stimulus. We first identified the suncus *Kiss1* and *Gpr54* genes and showed that sKp-29, deduced from cDNA

Fig. 5. Distribution of *Kiss1* mRNA-expressing cells in the hypothalamus of intact or OVX shrews with or without estradiol treatment. sequence, can stimulate presumed ovulation through GnRH release in musk shrews. GPR54 agonists also were able to induce presumed ovulation. These results indicate that the musk shrew has a kisspeptin–GPR54 signaling system that stimulates GnRH release and then ovulation. We found that *Kiss1*-expressing cells are located in the POA and ARC, as reported in other mammalian species (15, 18, 26) that are spontaneous ovulators. Interestingly, the mating stimulus largely induced c-Fos expression in *Kiss1*-expressing cells in the POA but not in the ARC. Collectively, these findings imply that the mating stimulus activates POA kisspeptin neurons and then GnRH release to induce ovulation in the musk shrew.

The present study shows that estradiol positively regulates POA *Kiss1* expression but negatively regulates the ARC *Kiss1* expression in the musk shrew. The result is consistent with other mammalian species, such as rodents, in which kisspeptin expression is regulated positively by estrogen in the anteroventral periventricular nucleus and negatively in the ARC (18, 26). The ARC *Kiss1* neurons might be a target of negative feedback of estrogen released from maturing follicles in the musk shrew, because *Kiss1* expression remained at a low level in intact musk shrews, whereas ovariectomy dramatically increased *Kiss1* expression.

The low level of c-Fos expression in the ARC *Kiss1* neurons after mating implies that ARC kisspeptin neurons are not involved in the mating-induced ovulation. Interestingly, unlike in other mammals, quite a large number of POA kisspeptin neurons remained in the OVX musk shrew. Rissman's group (27, 28) showed that the adrenal glands produce androgens that may be converted to estrogen in the POA to regulate sexual behavior in the female musk shrew. Likewise, *Kiss1* expression in the POA after ovariectomy might be maintained by adrenal androgens in the musk shrew.

In the present study, we identified two deduced forms of candidate kisspeptin peptides, sKp-29 and sKp-40. sKp-29 showed a potent stimulatory effect on presumed ovulation, but sKp-40 had no effect on ovulation, indicating that sKp-29 is an endogenous kisspeptin in the musk shrew. Interestingly, suncus kisspeptin is much shorter than reported in other mammals, in which kisspeptin consists of 52–54 amino acids (9, 17, 24). Indeed, exogenous administration of sKp-29 mimicked the mating

stimulus to induce presumed ovulation, and the sKp-29-induced ovulation was blocked completely by pretreatment with a GnRH antagonist. This result suggests that suncus kisspeptin stimulates GnRH release in the hypothalamus, as was reported in other spontaneous ovulators, and is potent enough to induce ovulation. The suncus kisspeptin sequence showed $\sim 80\%$ similarity with 29-amino acid sequences at the C terminus in other mammalian species. Kp-10, the core sequence of kisspeptin, also is highly conserved in other mammalian species. The C-terminal amino acid residue of Kp-10 is tyrosine, which is conserved in the mammals previously reported except for primates, which have phenylalanine at the C terminus (6, 14, 26). Like GPR54 in other vertebrates (10, 29, 30), suncus GPR54 possesses features typical of the class I rhodopsin-like guanine nucleotide-binding protein coupled receptor (GPCR) family (31): an N/DPxxY motif in the TM7 and a D/ERY/W motif in junction between TM3 and intracellular loop 2.

Exogenous sKp-29, but not sKp-10, administration mimicked the mating-induced follicular development and ovulation in the musk shrew. The difference between sKp-29 and sKp-10 might be related to differences in degradation rate in the body. Indeed, previous studies, including ours, demonstrated that rKp-52 or hKp-54 shows much higher induction of LH release than Kp-10 (32, 33) and suggested that rKp-52 and hKp-54 are more stable than Kp-10. This notion is in line with the current results demonstrating that administration (5 nmol) of two stable GPR54 agonists consisting of five amino acids, FTM080 and FTM145, induced ovulation in musk shrews, but the same dose of sKp-10 or rKp-10 did not. In fact, in vitro analysis demonstrated that hKp-10 is degraded completely in murine serum within 1 h, whereas FTM080 and FTM145 have half-lives in murine serum of 6.6 h and 38 h, respectively (34). hKp-10-injected shrews showed a much higher ovulation rate than sKp-10- and rKp-10-injected shrews. The difference in sequences between hKp-10 and other Kp-10s, such as sKp-10 and rKp-10, was found in a C-terminal amino acid: phenylalanine in hKp-10 and tyrosine in the other Kp-10s (Fig. 1). Indeed, both hKp-54 and hKp-10 showed much higher bioactivity than any other kisspeptins, suggesting that the C-terminal phenylalanine may be involved in higher binding affinity or a lower degradation rate in the musk shrew.

Peripheral administration of sKp-29 induced ovulation via GnRH release, suggesting that there are two possible sites of interaction between kisspeptin and GnRH neurons in the musk shrew: GnRH cell bodies located in the POA and GnRH neuronal termini located in the median eminence. GnRH neuronal termini are more likely to be the sites at which exogenous kisspeptin induces GnRH surges, because peripheral administration of kisspeptins or GPR54 agonists induced ovulation. The sites at which kisspeptin stimulates GnRH release should be clarified in the future.

The musk shrew has two GnRH systems, GnRH1 and GnRH2. The research group led by Rissman (35) showed that GnRH2 fibers project to the hypothalamus in the musk shrew brain, suggesting that GnRH2 also may be involved in the ovulation, and an injection of GnRH2 induces ovulation, although the effect is one-tenth that of GnRH1. Moreover, these investigators showed that central administration of GnRH2, but not GnRH1, significantly restored mating behavior in underfed females, implying that GnRH2 also may be involved in energy balance and reproductive behavior (36). The role of GnRH in ovulation could be clarified by revealing the neural circuit that includes kisspeptin neurons.

In conclusion, in the musk shrew the mating stimulus activates kisspeptin neurons in the POA to induce ovulation through the release of GnRH. Thus, kisspeptin–GPR54 signaling plays a role in inducing ovulation in a reflex ovulator, as it does in spontaneous ovulators. The key role of kisspeptin–GPR54 signaling in reproduction is well conserved in reflex ovulators as well as in spontaneous ovulators.

Materials and Methods

Animals. All animal experiments were conducted in accordance with the guidelines of the Committee on Animal Experiments of the Graduate School of Bioagricultural Sciences, Nagoya University. Male and virgin female KAT line musk shrews (*Suncus murinus*) were used at 2–12 mo of age. KAT line musk shrews were captured in Katmandu, Nepal and bred at Nagoya University. Animals were housed in a temperature-controlled ($25 \pm 2^\circ\text{C}$) room with 14 h light and 10 h darkness (lights on at 0600 h). All animals had free access to food (commercial trout pellets; Nippon Formula Feed Mfg Co., Ltd) and water. Some females were bilaterally ovariectomized 2 wk before the experiment to serve as the OVX group. Immediately after ovariectomy (i.e., 1 wk before the experiment), some of the OVX animals received s.c. Silastic tubing (i.d. 1.52 mm, o.d. 3.18 mm, 28 mm in length) filled with estradiol-17 β (E) (Sigma Chemicals) dissolved in peanut oil at 200 $\mu\text{g}/\text{mL}$ to serve as the OVX+E group.

Cloning Analysis. Three OVX female musk shrews were used for *Kiss1* and *Gpr54* cDNAs cloning. Total RNA was extracted from the hypothalamic tissues of each OVX musk shrew using TRIzol (Invitrogen). The cDNA encoding suncus *Kiss1* was obtained by 5' RACE and 3' RACE-PCR using the GeneRacer Kit (Invitrogen) with gene-specific primers according to the manufacturer's instructions. The gene-specific primers used in this study were designed based on the sequence deduced from the comparison of human, rat, and mouse mRNA sequences of *Kiss1* and human, rat, mouse, sheep, goat, and pig mRNA sequences of *Gpr54* (Table S1). All sequence data were obtained from the National Center for Biotechnology Information (<http://www.ncbi.nlm.nih.gov/>). The accession numbers for the mRNA sequences of *Kiss1* are human (NM_002256), rat (NM_181692), and mouse (NM_178260); the accession numbers for the mRNA sequences of *Gpr54* are human (AF343725), rat (AF115516), mouse (AF343726), sheep (HM135393), goat (GU142846), and pig (DQ459346).

RT-PCR Analysis. Total RNA was extracted from the cerebral cortex, hypothalamus, pituitary, heart, lung, liver, spleen, kidney, ovary, and uterus of female musk shrews and from the testis of male musk shrews using TRIzol. RT-PCR analysis was done using a thermal cycler (PC-818; ASTEC). Primers for the amplification of partial cDNA sequences of *Kiss1*, *Gpr54*, and 18S ribosomal RNA (18S rRNA) are shown in Table S1.

Ovulation-Induction Test. The amino acid sequence of suncus kisspeptin and its core sequence were deduced according to the cDNA sequence of the musk shrew. sKp-40 [suncus *Kiss1* gene product (81-120)-amide], sKp-29 [suncus

Kiss1 gene product (92-120)-amide], and sKp-10 [suncus *Kiss1* gene product (111-120)-amide] were synthesized by Hayashi Kasei Co., Ltd. hKp-10 [human *KISS1* gene product (112-121)-amide], rKp-10 [rat *Kiss1* gene product (110-119)-amide], and rKp-52 [rat *Kiss1* gene product (68-119)-amide] were synthesized by the Peptide Institute. hKp-54 was purchased from Phoenix Pharmaceuticals, Inc. FTM080 [4-fluorobenzoyl-Phe-Gly-Leu-Arg-Trp-NH₂] and FTM145 [4-fluorobenzoyl-Phe-Gly- ψ [(E)-CH=CH]-Leu-Arg-Trp-NH₂] were synthesized at Kyoto University as previously reported (34, 37, 38). Presumed ovulation was determined by microscopic examination of the fungiform corpus luteum formation in ovaries of individual animals. Female musk shrews (weight 44–63 g) were anesthetized briefly with diethyl ether and were injected s.c. with sKp-40, sKp-29, rKp-52, hKp-54, sKp-10, rKp-10, hKp-10, FTM080, or FTM145 (0.05–50 nmol/0.1 mL saline) or with saline (0.1 mL) alone at 1700 h ($n = 5$). Some of the animals injected with sKp-29 (0.5 nmol/0.1 mL saline) ($n = 4$) were pretreated with a GnRH antagonist (cetorelix, 200 nmol/0.2 mL 5% mannitol s.c.; AnaSpec) or vehicle (5% mannitol) 30 min before the sKp-29 injection. Ovaries were collected 3 d after the injection or mating.

Histochemical Analysis. Follicular development was determined by histological examination of the slit-like follicular cavity formation in ovaries of individual animals. Female musk shrews (weight 42–58 g) received a single s.c. injection of sKp-29 or sKp-10 (0.5 nmol/0.1 mL saline) at 1000 h ($n = 3$). Ovaries were collected 10 h or 3 d after the injection or mating and then were fixed with 10% neutral buffered formalin. The fixed ovaries were dehydrated through a graded ethanol series and embedded in Tissue Prep (Fisher Scientific). Sections (3- μm thickness) were made by a microtome and were mounted on a glass slide, deparaffinized, rehydrated, and then stained with H&E. Sections were examined under a light microscope.

In Situ Hybridization Analysis. To detect *Kiss1* mRNA, we performed in situ hybridization in the coronal cryostat sections (40- μm thickness) of hypothalamus taken from intact, OVX, and OVX+E animals as previously described (18). Digoxigenin (DIG)-labeled antisense and sense cRNA probes for suncus *Kiss1* were synthesized by in vitro transcription from the cDNA clones (Table S1). Hybridization with DIG-labeled cRNA probes was carried out at 60 $^\circ\text{C}$ overnight.

In Situ Hybridization and Immunohistochemical Analysis. Female shrews were assigned randomly to one of two groups: nonmated controls ($n = 3$) and mated animals ($n = 3$). The animals in the mated group then were mated with a male at 1100 h. The females were killed 1 h after the first ejaculation. They were perfused with the fixative, and brain tissue was obtained as described above. The nonmated females were perfused between 1300 and 1400 h. We performed dual staining for *Kiss1* mRNA by in situ hybridization and immunohistochemistry for c-Fos. After *Kiss1* mRNA was visualized by in situ hybridization without proteinase K treatment (18), the sections were washed with PBS and then incubated with a blocking buffer (3% normal goat serum, 1% BSA and 0.1% Triton X-100 in PBS) for 1 h. The sections were incubated with rabbit anti-cFos antibody (1:15,000; Ab-5; Calbiochem-Novabiochem) in a blocking buffer at 4 $^\circ\text{C}$ for 24 h. They were treated with biotin-conjugated goat anti-rabbit IgG (1:500; Vector Laboratories) in 0.1% Triton X-100 in PBS (PBST) for 1 h and then in avidin-biotinylated HRP complex (ABC Elite; Vector Laboratories) in PBST for 30 min. Finally, the sections were visualized with diaminobenzidine (DAB) solution (Dako). The number of *Kiss1*-expressing cells and c-Fos-immunoreactive cells was counted under a light microscope, and the total cell number in brain sections including the POA and ARC was obtained. The POA and ARC were identified using the brain mapping of Rissman and colleagues (39, 40). The POA was divided into three parts (POA1, POA2, and POA3) with four serial sections per part; 12 serial sections were examined. The ARC was divided into two parts (ARC 1 and ARC2) with seven serial sections per part; 14 serial sections were examined.

Statistics. Statistical differences in the ovulation rates were determined by Fisher's exact test, and statistical differences in the number of *Kiss1*-expressing cells and the percentage of *Kiss1*-positive cells expressing c-Fos immunoreactivity were determined by unpaired student's *t* test.

ACKNOWLEDGMENTS. We thank Dr. Sen-ichi Oda (Okayama University of Science) for providing the KAT line musk shrews and Shiori Minabe (Nagoya University) for technical support.
