Abstract

Mycobacterium tuberculosis, the causative agent of tuberculosis, is unique among bacterial pathogens in that it contains a wide array of complex lipids and lipoglycans on its cell wall. Among them, the sulfated glycolipid, termed sulfolipid is thought to mediate specific host pathogen interactions during infection. Sulfolipids (SLs) including sulfolipid I (SL-I) and sulfolipid II (SL-II) are 2,3,6,6'-tetraacyltrehalose 2'-sulfates. SL-I was identified as a family of homologous 2-palmitoyl(stearoyl)-3-phthioceranyl, 6,6'-bis(hydroxyphthioceranyl)-trehalose 2'-sulfate and was believed to be the principal sulfolipid of *Mycobacterium tuberculosis* strain H37Rv. We cultured and extracted sulfolipids using various conditions including those originally described and employed high-resolution multiple-stage linear ion-trap mass spectrometry with electrospray ionization to characterize the structure of the principal SL. We revealed that SL-II, a family of homologous 2-stearoyl(palmitoyl)-3,6,6'-tris(hydroxyphthioceranyl)-trehalose 2'-sulfates, rather than SL-I is the principal sulfolipid class. We identified a great number of isomers resulting from permutation of the various hydroxyphthioceranyl substituents at 6- and 6'-position of the trehalose backbone for each of the SL-II species in the entire family. We redefined the structure of this important lipid family that was mis-assigned using the traditional methods 40 years ago.

Introduction

Mycobacterium tuberculosis contains a range of complex glycolipids with a trehalose backbone, including a family of sulfated acyl trehaloses that was first recognized by Middlebrook et al in the virulent Tubercle bacilli (1). This family of sulfated acyl trehaloses defined as sulfolipids (SLs) were characterized by Goren and coworkers in their early studies on *M. tuberculosis* H37Rv (2-5). The principal SLs were characterized as sulfolipid-I (SL-I), which is a homologous mixture of 2,3,6,6'-tetraacyl- α , α' -D-trehalose-2'-sulfate consisting of a pair of 2,4,6,8,10,12,14,16-Octamethyl-17-hydroxydotriacontanoate (hydroxyphthioceranoic acid) located at 6, and 6'-position, and a nonhydroxylated multiple methyl-branched derivative (phthioceranoic acids) and a short saturated fatty acid (palmitic acid or stearic acid) located at the 3- and 2-position of the trehalose backbone, respectively. In addition to the major SL-I, minor species that were termed as SL-II (2-palmitoyl/stearoyl-3,6,6'-tris-hydroxyphthioceranoyl-2'-sulfate), SL-I' (2-palmitoyl/stearoyl-3,6-bis-phthioceranoyl-6'-hydroxyphthioceranoyl-2'-sulfate) and SL-II' (2-palmitoyl/stearoyl-4,6,6'-tris-hydroxyphthioceranoyl-2'-sulfate) were also reported. However, the structural studies on SLs have been focused on SL-I (4).

A wealth of *in vivo* and *in vitro* studies that point to the role of sulfolipids in the virulence of the tubercle bacillus have been documented. For example, Okamoto et al reported that SL could contribute to virulence at early stage of mycobacterial infection or stimulation with the glycolipids by counteracting the immunopotentiating effect of TDM (6). *In vitro*, SL-I induced swelling and disruption of mitochondrial membranes and strongly inhibited mitochondrial oxidative phosphorylation (7). *M. tuberculosis* sulfolipids are also capable of preventing phagosome-lysosome fusion in cultured macrophages (8). From *in vitro* studies, Zhang and coworkers reported the remarkable properties of sulfolipids, including their ability to modulate the oxidative response and the cytokine secretion of human monocytes and neutrophils (9, 10). It was also found that diacylated sulfoglycolipids are mycobacterial antigens that can stimulate CD1-restricted T cells during infection with *M. tuberculosis* (11-13). Studies addressing the aspects of the biosynthesis and the function of SL-1 *in vivo* have recently begun to emerge (14-17). However, its function in the life cycle of the *M. tuberculosis* remains largely unknown.

The structures of sulfolipids are complex, and studies toward the structural definition of SL-I conducted by Goren and coworkers 40 years ago is a showcase of the exceptional talent of scientists of their generation. They were able to deduce the complex structure of unknown compounds using the traditional methods that required many laborious steps to a large-scale separation and purification, followed by multiple chemical reaction steps and chromatographic separations, in conjunction with various spectroscopic techniques including IR, NMR and mass spectrometry for structure analysis (2-4). In this contribution, we describe a simple and direct electrospray ionization (ESI) mass spectrometric approach employing multiple-stage and high-resolution mass spectrometry for structural elucidation of the sulfolipids of *M. tuberculosis* H37Rv, the same strain previously described by Goren et al (2-5). When cultured and extracted using various conditions including those described by Goren, we found that SL-II not SL-I is always the principal sulfolipid class. Our data are similar to those reported by others who nevertheless referred it as SL-I (4, 16, 18-20). Our approaches using various mass spectrometric techniques permit us to reveal the detailed structures of SLs including the various isobaric isomers that had been reported but not confirmed by the traditional methods.

Experimental procedures

Materials

Sulfolipid-1 standard was supplied by the Mycobacteria Research Laboratories at Colorado State University (CSU) as part of the TB Research materials contract that is currently administered by BEI Resources

(<http://www.beiresources.org/TBVTRMResearchMaterials/tabid/1431/Default.aspx>).

According to standard operating protocols, the SL-I standard was harvested from *M. tuberculosis* H37Rv that had been grown in glycerol-alanine salts (GAS) broth, killed (γ -irradiation) and extracted using chloroform and methanol. All other chemicals used are spectroscopic grade and were purchased from Sigma Chemical Co.

Culture media

Modified Wong-Weinzirl broth was prepared and autoclaved as described by Goren (2). The broth was composed of malic acid (0.3%), NH_4OH (0.12%), ammonium citrate (0.5%), KH_2PO_4 (0.6%), anhydrous Na_2CO_3 (0.2%), NaCl (0.2%), MgSO_4 (0.1%), ammonium iron(III) citrate (0.005%), glycerol (0.05% v/v), and glucose (0.2%), supplemented with sodium pyruvate (0.05%), Cu^{2+} (0.0001%) and Zn^{2+} (0.0001%). Middlebrook 7H9 broth and Middlebrook 7H10 plates (BD, Franklin Lakes, NJ) were prepared according to manufacturer instructions with supplemental OADC enrichment and Tween-80 (0.05%). Glycerol-alanine-salts (GAS) broth contained (per liter) 2 g of NH_4Cl , 1 g of L-alanine, 0.3 g of Bacto casitone (Difco), 4 g of K_2HPO_4 , 2 g of citric acid, 50 mg of ferric ammonium citrate, 1.2 g of $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$, 0.6 g of K_2SO_4 , 1.8 ml of 10 M NaOH, 10 ml of glycerol, and Tween 80 (0.05%).

Mycobacterial culture and harvest

Seed stocks of *M. tuberculosis* (H37Rv or CDC1551) were grown for 7-10 days (O.D 0.7–0.9) in 7H9-OAD at 37 °C. For broth-grown cultures, 250 ml of broth was inoculated (1:500) and incubated at 37 °C for 4-6 weeks to late-log phase. Pellicles formed in the modified Wong-Weinzirl broth, and flocculent cultures grew in the 7H9 broth. Broth cultures were harvested by centrifugation at 3000 rpm, and the pellets were washed successively in PBS/Tween (0.05%). For plate-grown cultures, seed cultures were diluted 1:10 in PBS/Tween and vortexed; and 4 ml was spread onto 7H10 agar (150 cm-dia. plates) and incubated at 37 °C for 6 weeks. Confluent growth with a dry, waxy appearance was scraped into collection tubes and weighed.

Lipid extraction

Pellets of live bacilli were extracted in hexane-decylamine or chloroform:methanol (C/M) (2:1; v:v). Plate-grown pellets were extracted three times (100 ml solvent per 100 g). Hexane-decylamine extractions were performed as described by Goren (2). Briefly, the first extraction was in 0.1% decylamine (4°C for 1-4 weeks), and the subsequent extractions were in 0.5% decylamine with sonication for 30 min at room temperature. For C/M extractions, washed pellets were extracted the first time at 4°C for 1-4 weeks and subsequently with sonication for 30 min at room temperature. Extracts were pooled, filtered (0.2 micron, PTFE filters) and dried on a rotary evaporator. To remove decylamine, residues were dissolved in hexane, and an equal volume of citric acid (1N) was added. The flask was shaken and allowed to separate. The top phase was percolated through a column (8cm length; 0.7 cm dia.) of anhydrous H_2SO_4 and chased with 1 column volume of hexane. The eluent was dried under nitrogen. All crude extracts were stored dried and under nitrogen at -70 °C.

Thin Layer Chromatography

Lipid extracts were dissolved in hexane. If a sample was insoluble, chloroform:methanol (2:1) was added until the sample dissolved completely. Lipids were spotted onto silica gel 60 TLC plates (EM Science) and developed in a 2-solvent system as previously reported by Goren et al. (2). Plates were developed first in chloroform:methanol:acetic acid:water (95:1:5:0.3; v:v) to 20 cm, dried, and then re-developed in chloroform:acetone:methanol:water:acetic acid (158:83:1:6:32; v:v) to 15 cm. Plates were sprayed with ethanolic sulfuric acid (50%) and charred with a heat gun. Samples that were fractionated by preparative TLC were loaded across a TLC plates and developed successively in the same solvent systems for 20 cm and 18 cm, respectively. A strip of the plate was charred to visualize lipid bands, and the corresponding areas were scraped into separate tubes and extracted from the silica with hexane followed by chloroform:methanol (2:1), each for 5 min at 45 °C with sonication. The two extracts were combined, dried under nitrogen and stored at -70 °C.

Mass spectrometry

Low-energy collision-induced dissociation (CID) tandem mass spectrometry experiments were conducted on a Thermo Scientific (San Jose, CA) LTQ Orbitrap Velos and a LIT-FT mass spectrometers (MS) with Xcalibur operating system. High-resolution mass spectrometry was also performed on a Bruker solariX (Bremen, Germany) 12 Tesla FTMS system, which provides baseline resolution among ions from SL-I and SL-II. Solution of sulfolipid in methanol was infused (1.5 $\mu\text{L}/\text{min}$) to the ESI source, where the skimmer was set at ground potential, the electrospray needle was set at 4.0 kV, and temperature of the heated capillary was 300°C. The automatic gain control of the ion trap was set to 5×10^4 , with a maximum injection time of 100 ms. Helium was used as the buffer and collision gas at a pressure of 1×10^{-3} mbar (0.75 mTorr). The MS^n experiments were carried out with an optimized relative collision energy ranging from 35-40% and with an activation q value at 0.25, and the activation time at 10 ms to leave a minimal residual abundance of precursor ion (around 20%). The mass selection window for the precursor ions was set at 4 Da wide to include the monoisotopic species to the ion-trap for collision-induced dissociation. For higher-energy collision-induced dissociation (HCD), precursor ions were selected in the linear ion trap and fragmentation in the multipole HCD collision cell with high resolution accurate mass detection in the Orbitrap mass analyzer. Mass spectra were accumulated in the profile mode, typically for 3-10 min for MS^n -spectra ($n=2,3,4$).

Nomenclature

To facilitate data interpretation, the following abbreviations were adopted. The abbreviation of the nonhydroxylated multiple methyl-branched phthioceranoic acids, for example, the 2,4,6,8,10,12,14,16-Octamethyl-dotriacontanoic acid is designated as C_{40} -acid to reflect the fact that the structure consists of 40 saturated hydrocarbon chain. For hydroxydotriacontanoic acids, for example, 2,4,6,8,10,12,14,16-Octamethyl-17-hydroxydotriacontanoic acid is designated as hC_{40} -acid to reflect that the compound consists of 40 hydrocarbon chain with one hydroxyl group attached at C-17. Therefore, the principal SL-II species (the position of the substituents on the trehalose backbone is adopted from the definition by Goren (4)), which is a 2-stearoyl-3,6,6'-tris-2,4,6,8,10,12,14,16-Octamethyl-17-hydroxydotriacontanoyl- α, α' -D-trehalose-2'-sulfate is designated as (18:0, hC_{40} , hC_{40} , hC_{40})-SL, signifying that the compound consists of one stearoyl and three 2,4,6,8,10,12,14,16-Octamethyl-17-hydroxydotriacontanoyl groups located at 2-, 3-, 6-and 6'-position of the trehalose backbone, respectively; while SL-I molecule such as 2-palmitoyl-3-2,4,6,8,10-Pentamethyl-pentacosanoyl-6,6'-bis-2,4,6,8,10,12,14,16-Octamethyl-17-hydroxydotriacontanoyl- α, α' -D-trehalose-2'-sulfate is designated as (16:0, C_{30} , hC_{40} , hC_{40})-SL.

Results and Discussion

Crude sulfolipid extracts from different culture media and extraction methods

Various culture media and extraction methods have been used in reports characterizing the SLs from *M. tuberculosis* H37Rv (2, 11, 16, 19). To determine whether such variables could alter the relative abundance of the major SL families, H37Rv was cultured to late-log phase in four culture mediums, and two extraction methods were performed. H37Rv and a clinical isolate (CDC1551; data not shown) yielded relatively abundant SLs in crude lipid extracts under all conditions (Figure 1). Glycolipids appeared as prominent red spots or streaks TLC plates upon spraying with sulfuric acid and heating, and spots with approximate R_f s of 0.44 and 0.49 that were scraped from prepTLC plates were confirmed to be SLs by ESI mass spectrometry in the negative-ion mode. The most abundant SL exhibited an R_f of 0.44 with mobility identical to the SL-I family and a less abundant SL (R_f 0.49) which was apparent in hexane-decylamine extracts, corresponding to the SL family that was designated SL-II by Goren (2, 4).

Sulfolipids from plate-grown cultures were especially abundant. SLs were also readily extracted from broth-grown cultures despite some culture-to-culture variation in the amounts of crude lipid (Figure 1; lanes 5 and 9 vs. lane 6). The SLs that migrated at R_f 0.44 were always the most abundant SL family in all broth cultures. Hexane-decylamine or chloroform-methanol extraction methods isolated the major SL family; however, hexane-decylamine extraction was more efficient for isolating the SLs that migrated at R_f 0.49, as described by Goren (2). Another parameter that was explored briefly was whether live and dead bacterial pellets yielded the same relative abundance of SL families. Preliminary studies showed no significant differences in crude extracts from heat-killed (autoclaved) vs. live bacterial pellets. Taken together, these data indicate that the SL family with an R_f of 0.44 in our TLC system is the most abundant family, irrespective of differences in commonly used culture media and extraction methods.

High-resolution mass spectrometry on the $[M - H]^-$ ions of sulfolipids

We examined the SLs isolated from *M. tuberculosis* strain H37Rv and strain CDC1551 grown in 7H9 broth, and in modified Wong-Weinzirl broth, together with the sulfolipid standard obtained from the Mycobacterial Research Laboratories at Colorado State University using ESI mass spectrometry in the negative-ion mode. An array of the $[M - H]^-$ ions in the range of 2000-2900 Da, with an intermittence of 14 Da were observed. The ESI/MS profiles of the SLs from H37Rv grown in 7H9 broth (Figure 2) and from the SL standard (not shown) are similar, and the profiles are also similar to those previously reported (16, 18-21); while the SL profiles from strain H37Rv grown in modified Wong-Weinzirl broth (See supplemental data, Figure S1) are also similar, and the ions representing SL-II are the dominant species, but the average M.W. is 56 Da higher than that obtained from 7H9 broth. The results indicate that the length of the hydroxyphthioceranoic acid substituents of SLs is dependent on the growth conditions. High-resolution mass spectrometric analysis on the ion series with an increment of 14 Da using an FT-ICR instrument (Resolution ~500,000) confirmed that the 14 Da increment corresponds to a CH_2 residue and the homologous $[M - H]^-$ ions ranged from 1900 to 2750 Da all possess an elemental composition of $C_{120}H_{229}(CH_2)_nO_{21}S_1$ ($n = 0, 1, 2, \dots, 60$) (See supplemental data, Table S1), in which the nominal masses for the monoisotopic peaks at m/z 2333, 2375, 2417, 2459, ..., 2501 are among the most prominent (Figure 2, ions marked with "▼"). This ion series consists of palmitoyl/stearoyl, three hydroxyphthioceranoyl and one sulfate residues on the trehalose backbone and was previously defined as SL-II by Goren and coworkers (4). The spectrum also contained the ion series with nominal monoisotopic masses that are 2 Da lighter (see Figure 2, ions marked with "*"), similar to that recently reported by Layre et al

(21). High resolution mass measurements on these ions (Table S1) indicate that these ions possess an elemental composition of $C_{120}H_{229}(CH_2)_nO_{20}S_1$ ($n = 0, 1, 2, \dots, 60$), corresponding to the SL-I structures previously defined (4).

The separation of the ion clusters of SL-I from those of SL-II (Figure 2, inset a) (Figure 2, inset a) also provides the accurate profile of the isotopic cluster ions for confirmation of elemental composition. For example, the monoisotopic ion observed at m/z 2359.0380 (Figure 2, inset a) corresponds to an elemental composition of $C_{144}H_{277}O_{20}S$ (calculated m/z : 2359.0384), which gave a simulated spectrum (Inset b, ions labeled with “*”) similar to the experimental (Inset a, ions labeled with “*”). The monoisotopic ion observed at m/z 2361.0172 and its isotopic ion cluster pattern (Inset a; ions labeled with “▼”) are also consistent with the elemental composition of $C_{143}H_{275}O_{21}S$ (calculated mass: 2361.0177; the simulated plot of the isotopic ion clusters is labeled with “▼” in Inset c), indicating the presence of SL-II. The mass spectrometric approaches toward structural characterization of the major sulfolipid species (i.e., SL-II) are described below.

Structural analysis of SL-II by multiple-stage mass spectrometry in conjunction with high-resolution accurate mass measurements

High-resolution mass measurement on the $[M - H]^-$ ion of the monoisotopic ion of m/z 2459 (base peak) and its isotope ion cluster profile led to an elemental composition of $C_{150}H_{289}O_{21}S_1$ (calculated: 2459.1272, measured: 2459.1272), corresponding to a SL-II molecule (Table S1; Figure 2).

The MS^2 spectra of the ions of m/z 2459.1 following CID (Figure 3a) and HCD (Figure 3b) yielded prominent ion at m/z 1850.6 (2459.1 – 608.6), corresponding to loss of a C_{40} -hydroxyphthioceranoic acid residue probably residing at 3 position of the trehalose core of the SL. The spectra also contained the abundant ion at m/z 1566.3 from further loss of a stearic acid (18:0-acid) residue at the 2-position of the trehalose skeleton. This consecutive loss of the 18:0-fatty acid is supported by CID MS^3 spectrum of the ion at m/z 1850 (2459.1 → 1850.6; Figure 3c), which is dominated by the ion at m/z 1566.3 (1850.6 – 284.3). The ion of m/z 1566.3 can also arise from primary loss of the 18:0-fatty acid, followed by loss of a C_{40} -hydroxyphthioceranoic acid. These fragmentation processes were supported by the observation of the ion at m/z 1566.3 in the MS^3 spectrum of the ion at m/z 2174.8 (2459.1 → 2174.8; Figure 3d), and consistent with the presence of the ion at m/z 2174.8 (2459.1 – 284.3) in Figure 3a. The prominence of the ions of 1850 and 1566 (Figure 3a and 3b) may indicate the preferential losses of the 3-acyl and 2-acyl substituents as the free fatty acid over those located at 6 or 6', and are consistent with the notion of the greater stability of the substituents at 6 (or 6') towards acid or alkaline hydrolysis as compared with those located at 3- and 2-position (5). The MS^4 spectrum of the ion of m/z 1566.3 (2459.1 → 1850.3 → 1566.3; Figure 3e) is identical to the MS^3 spectrum of the m/z 1566.3 ion (2459.1 → 1566.3) (not shown), and the spectrum is dominated by the ion at m/z 957.7 (1566.3 – 608.6), arising from further loss of a C_{40} -hydroxyphthioceranoic acid residue, residing at 6-, or 6'-position. The spectrum also contained the ions at m/z 849.5 and 831.5, corresponding to a 6'- C_{40} -hydroxyphthioceranyl-glucose-2'-sulfate and dehydrated 6'- C_{40} -hydroxyphthioceranyl-glucose-2'-sulfate anions, respectively. These two ions consist of the glucose moiety originally bearing the lone acyl group and the sulfate substituent, and were formed by further elimination of a $C_6H_4O_2$ and a $C_6H_6O_3$ residues from m/z 957, respectively, supporting that a C_{40} -hydroxyphthioceranyl is located at 6'. This latter fragmentation process is supported by the MS^4 spectrum of the ion of m/z 957 (2459.1 → 1566.3 → 957.7; Figure 3f). The MS^5 spectrum of the ion at m/z 831.5 (2459.1 → 1566.3 → 957.7 → 831.5; Figure 3g) is dominated by the ion at m/z 607.5 (831.5 – 224) representing a 6'- C_{40} -hydroxyphthioceranoic anion and the ion at m/z 223, representing a dehydrated glucose-2'-sulfate anion (Scheme 1; Figure 3b), confirming that the ion at m/z 831 indeed contains the

glucose moiety originally bearing the lone acyl residue and the sulfate substituent and represents a 6'-C₄₀-hydroxyphthioceranoyl-glucose-2'-sulfate anion. The above results indicate that the major ion at *m/z* 2459.1 represents a 2-stearoyl-3,6,6'-tris-2,4,6,8,10,12,14,16-Octamethyl-17-hydroxydotriacontanoyl- α,α' -D-trehalose-2'-sulfate ([18:0, hC₄₀, hC₄₀, hC₄₀]-SL). The fragmentation processes were further supported by the elemental compositions of the fragment ions obtained from the high-resolution CID and HCD tandem mass spectra (Table 1). The HCD MS² spectrum of the ion of *m/z* 2459.1 (Figure 3b) contained the tandem quadrupole-like spectrum, which is dominated by the hydroxyphthioceranoic acid anion of *m/z* 607 (measured: 607.6032; calculated:607.6034) with an elemental composition of C₄₀H₇₉O₃⁻, consistent with the suggested structure of 2,4,6,8,10,12,14,16-Octamethyl-17-hydroxydotriacontanoyl acid, along with the homologous ions at *m/z* 691, 649, 635, 565 and 523 (Table 1). The characterization of hydroxyphthioceranoic acid was further achieved by its MSⁿ spectra, which is described later.

In Figure 3c, the ion at *m/z* 1594.3 arising from further loss of 16:0-fatty acid residue is also present, consistent with the observation of the ion at *m/z* 2202.8 in Figure 3a. The results indicate the presence of the isomer bearing a 16:0-fatty acid substituent at the 2-position and a C₄₀-hydroxyphthioceranoic acid residue mostly likely at the 3-position. The ion of *m/z* 1594.3 can also arise from the losses in a reversed manner (i.e., first loss of palmitoyl group followed by C₄₀-hydroxyphthioceranoic acid residue), similar to the formation of the ion of *m/z* 1568 as described earlier. Further dissociation of the ion of *m/z* 1594.3 (2459.1 → 1594.3; Figure 3h) yielded ions of *m/z* 985 and 957, arising from losses of a C₃₈-hydroxyphthioceranoic and a C₄₀-hydroxyphthioceranoic acids respectively, along with ions at *m/z* 635 and 607, representing a C₄₂-hydroxyphthioceranoic and C₄₀-hydroxyphthioceranoic anions, respectively. The results indicate the presence of a C₄₂-hydroxyphthioceranoic and a C₄₀-hydroxyphthioceranoic residues at 6- or 6'-position. The spectrum also contained the ions at *m/z* 859 and 831, corresponding to a 6'-C₄₂-hydroxyphthioceranoyl-glucose-2'-sulfate and 6'-C₄₀-hydroxyphthioceranoyl-glucose-2'-sulfate anions, respectively. These results indicate that both the C₄₂- and C₄₀-hydroxyphthioceranoyl groups can reside at the 6'-position, suggesting the presence of 2-palmitoyl-3,6-bis-2,4,6,8,10,12,14,16-Octamethyl-17-hydroxydotriacontanoyl-, 6'-2,4,6,8,10,12,14,16-Octamethyl-17-hydroxytetracontanoyl- α,α' -D-trehalose-2'-sulfate ([16:0, hC₄₀, hC₄₀, hC₄₂]-SL) and 2-palmitoyl-3,6'-bis-2,4,6,8,10,12,14,16-Octamethyl-17-hydroxytetracontanoyl- α,α' -D-trehalose-2'-sulfate ([16:0, hC₄₀, hC₄₂, hC₄₀]-SL) isomers. The observation of these latter two isomers indicates that the 2-substituent appears to be restricted as previously reported (2-4), while the substituents at the 6 and 6' positions are interchangeable. Again, the structural assignments of the fragment ions are consistent with the elemental composition deduced from high-resolution mass measurements (Table 1). Collectively, the ion at *m/z* 2459.1 represents a major [18:0, hC₄₀, hC₄₀, hC₄₀]-SL isomer together with two minor isomers of [16:0, hC₄₀, hC₄₀, hC₄₂]-SL and [16:0, hC₄₀, hC₄₂, hC₄₀]-SL.

In Figure 3b, minor C₄₆⁻, C₃₇⁻, C₃₄-hydroxyphthioceranoic anions at *m/z* 691, 565, 523 were also observed; and the minor homologous ions at *m/z* 1766, 1892, and 1934 arising from losses of the C₄₆⁻, C₃₇⁻, C₃₄-hydroxyphthioceranoic acid were also present in Figure 3a. These results indicate the presence of the minor isomers possessing the C₄₆⁻, C₃₇⁻, and C₃₄-hydroxyphthioceranoic acid substituents. Further dissociation of the ion of 1524 (2459.1 → 1524.2; data not shown) yielded the ion pairs at *m/z* 957/915 and 999/873 arising from losses of and a C₃₇/C₄₀⁻ and C₃₄/C₄₃-hydroxyphthioceranoic acids, together with the C₃₇⁻, C₄₀⁻, C₃₄⁻ and C₄₃-hydroxyphthioceranoic anions at *m/z* 565, 607, 523, and 649. The results support the presence of [18:0, hC₄₆, hC₄₀, hC₃₇]-SL and [18:0, hC₄₆, hC₄₃, hC₃₄]-SL isomers. The presence of these minor isomers is consistent with the observation of the minor

ion at m/z 1524 in Figure 3d, arising from consecutive losses of 18:0-fatty acid and C_{46} -hydroxyphthioceranoic acid. The structural assignments were also supported by accurate mass measurements (Table 1).

Similarly, the MS^2 spectrum of the ion at m/z 2543.2 (Figure 4a) contained the ions at m/z 2286 and 2258, arising from loss of a 16:0-, and 18:0-fatty acid residues, respectively. The ions at m/z 1934, 1906, 1892, and 1850 arise from losses of the C_{40} -, C_{42} -, C_{43} -, and C_{46} -hydroxyphthioceranoic residues at 3-position, respectively. The sequential losses of the 18:0-fatty acid at 2-position gave rise to ions at m/z 1650, 1622, 1608, and 1566, respectively; while the ion at m/z 1678 mainly arise from further loss of a 16:0-fatty acid residue from m/z 1934. The profile of the ion set of m/z 1934, 1906, 1892 and 1850 is similar to that of the ion set of m/z 1650, 1622, 1608, and 1566 (Figure 4a), consistent with the fragmentation mechanisms that first eliminate the 3-hydroxyphthioceranoic acid residue followed by loss of the 18:0-fatty acid at 2-position (or vice versa) as described earlier. The results indicate that the ion at m/z 2543 consists of the isomers in which the 3- and 2-position having $hC_{40}/18:0$ -, $hC_{42}/18:0$ -, $hC_{43}/18:0$ -, and $hC_{46}/18:0$ - and $hC_{40}/16:0$ -fatty acid substituents. The prominence of these ion pairs (e.g., ions of m/z 1934 and 1650), again, indicate the preferential losses of the substituents at 2 and 3 over those located at 6 or 6', which have the greater stability towards acid or alkaline hydrolysis as compared with the substituents at 3- and 2-position (5).

Further dissociation of the ion of m/z 1650 ($2543 \rightarrow 1650$; Figure 4b) yielded the major ions at m/z 1041 and 999, together with m/z 957, arising from loss of C_{40} -, C_{43} -, and C_{46} -hydroxyphthioceranoic acids, respectively. The results are consistent with the observation of the major C_{40} -, and C_{46} -hydroxyphthioceranoic acid anions at m/z 607 and 691, as well as the presence of the C_{43} -hydroxyphthioceranoic acid anion at m/z 649. The spectrum also contained the 6'- C_{40} -, 6'- C_{43} -, and 6'- C_{46} -hydroxyphthioceranyl-glucose-2'-sulfate anions at m/z 831, 873, and 915, indicating that the ion at m/z 2543 consists of major [18:0, hC_{40} , hC_{40} , hC_{46}]-SL and [18:0, hC_{40} , hC_{46} , hC_{40}]-SL isomers together with minor isomer of [18:0, hC_{40} , hC_{43} , hC_{43}]-SL..

MS^3 on the ion of m/z 1678 ($2543 \rightarrow 1678$; Figure 4c) yielded ions at m/z 1041 (loss of 636), 985 (loss of 692), 1069 (loss of 608), 957 (loss of 720), 999 (loss of 678), 1027 (loss of 650), consistent with the observation of the hydroxyphthioceranoic anions of m/z 635, 691, 607, 719, 677, and 649 that represent C_{42} -, C_{46} -, C_{40} -, C_{48} -, C_{45} -, or C_{43} -hydroxyphthioceranoic acid, respectively. The spectrum also contained the ions at m/z 859, 915, 831, 943, 901, and 873, indicating the presence of 6'- C_{42} -, 6'- C_{46} -, 6'- C_{40} -, 6'- C_{48} -, 6'- C_{45} -, or 6'- C_{43} -hydroxyphthioceranyl-glucose-2'-sulfate anions as seen earlier. The observation of the abundant ion pairs at m/z 1041 (loss of hC_{42}) and 985 (loss of hC_{46}) signifies the presence of the major [16:0, hC_{40} , hC_{42} , hC_{46}]-SL and [16:0, hC_{40} , hC_{46} , hC_{42}]-SL isomers; while the 1069/957 pairs lead to the assignment of [16:0, hC_{40} , hC_{40} , hC_{48}]-SL and [16:0, hC_{40} , hC_{48} , hC_{40}]-SL isomers; and the minor 999/1027 ion pairs give assignment of isomers of [16:0, hC_{40} , hC_{43} , hC_{45}]-SL and [16:0, hC_{40} , hC_{45} , hC_{43}]-SL.

As described earlier, the ions at m/z 1566 and 1594 arose from the consecutive losses of the C_{46} - and C_{44} -hydroxyphthioceranoic acid, respectively, followed by loss of the 18:0-fatty acid residue at C-2. Further dissociation of the ion at m/z 1566 ($2543 \rightarrow 1566$) yielded the spectrum identical to that shown in Figure 4c, indicating the presence of C_{40} -hydroxyphthioceranoic acid residues at 6 and 6'. The results lead to the assignment of [18:0, hC_{46} , hC_{40} , hC_{40}]-SL isomer, which is a positional isomer to [18:0, hC_{40} , hC_{40} , hC_{46}]-SL and [18:0, hC_{40} , hC_{46} , hC_{40}]-SL as seen earlier. The profile of the MS^3 spectrum of the ion at m/z 1594 ($2543 \rightarrow 1594$; not shown) is also similar to that shown in Figure 4f, and is dominated by the ions at m/z 985 ($1594 - 608$) and 957 ($1594 - 636$), indicating the

presence of [18:0, hC₄₄, hC₄₀, hC₄₂]-SL. Similarly, the MS³ spectrum of the ion at *m/z* 1608 (2543 → 1608; Figure 4d) is dominated by the ions at *m/z* 999 and 957, arising from losses of the C₄₀⁻, and C₄₃-hydroxyphthioceranoic acids, respectively; consistent with the observation of the C₄₀⁻, and C₄₃-hydroxyphthioceranoic anions at *m/z* 607 and 649. These results further support the presence of the [18:0, hC₄₀, hC₄₃, hC₄₃]-SL isomer.

More minor isomeric structures were revealed by MS³ on the ions at *m/z* 1636 (2543 → 1636; Figure 4e), and at *m/z* 1622 (2543 → 1622; Figure 4f). The former spectrum contained the *m/z* 985/999 ion pair from loss of C₄₃⁻/C₄₂-hydroxyphthioceranoic acids, as well as the *m/z* 1027/957 ion pair from loss of the C₄₀⁻/C₄₄-hydroxyphthioceranoic acids. These results give assignment of [18:0, hC₄₁, hC₄₃, hC₄₂]-SL and [18:0, hC₄₁, hC₄₀, hC₄₅]-SL isomers. The latter spectrum (Figure 4f) is dominated by *m/z* 985/985, and 957/1013 ion pairs, arising from losses of C₄₂⁻/C₄₂-hydroxyphthioceranoic acids and C₄₃⁻/C₄₁-hydroxyphthioceranoic acids, respectively, leading to assignment of isomers of [18:0, hC₄₂, hC₄₂, hC₄₂]-SL and [18:0, hC₄₂, hC₄₃, hC₄₁]-SL. Collectively, the ion of *m/z* 2543 consists of more than 12 isomers in which [18:0, hC₄₀, hC₄₀, hC₄₆]-SL and [18:0, hC₄₀, hC₄₃, hC₄₃]-SL predominate. This structural complexity in a single species of SLs was recently reported with less detail by Layre et al (21).

To reveal the shortest hydroxyphthioceranoic chain that constitutes the SL-II molecules, MSⁿ was conducted on the low mass end ion of *m/z* 2122.8. The MS² spectrum (see supplemental data; Figure S2a) is dominated by the ion at *m/z* 1640, arising from loss of C₃₁-hydroxyphthioceranoic acid, together with ions at *m/z* 1356 from further loss of 18:0-fatty acid, indicating the presence of 18:0-, and hC₃₁-acids at 2- and 3-position. Further dissociation of the ion of *m/z* 1356 (2122.8 → 1356; Figure S2b) gave rise to 957/747 and 873/831 ion pairs by further elimination of C₂₅⁻/C₄₀-hydroxyphthioceranoic and C₃₁⁻/C₃₄-hydroxyphthioceranoic acids, respectively. These results led to the assignment of [18:0, hC₃₁, hC₂₅, hC₄₀]-SL and [18:0, hC₃₁, hC₃₁, hC₃₄]-SL structures. The loss of the hC₂₅/hC₄₀-acids is consistent with the observation of the hC₂₅/hC₄₀ anion at *m/z* 397 and 607 (Figure S2b). The ion at *m/z* 397 corresponds to a 2,4,6-Trimethyl-7-hydroxydodecanoric acid anion possessing 2 repeating isopropyl (-CH₂CH(CH₃)-) unit. This short-chain hydroxyphthioceranoic acid chain was recently reported by Layre et al (21) but not previously reported by Goren (4). The structural assignment is consistent with the observation of the ion pairs of *m/z* 1724/1514 and 1640/1598 in Figure S2a, arising from losses of hC₂₅/hC₄₀ (398/608), and hC₃₁/hC₃₄ (482/524). The observation of the ion of *m/z* 1384 from the consecutive losses of C₃₁-hydroxyphthioceranoic acid and 16:0-fatty acid (Figure S2b), together with the ion pairs of *m/z* 859/873, 775/957, and 747/985 (2122.8 → 1384; Figure S2c) arising from loss of hC₃₄/hC₃₃, hC₄₀/hC₂₇, and hC₄₂/hC₂₅, respectively, readily give assignments of isomers of [16:0, hC₃₁, hC₃₃, hC₃₄]-SL, [16:0, hC₃₁, hC₂₇, hC₄₀]-SL, and [16:0, hC₃₁, hC₂₅, hC₄₂]-SL.

For further insight into the long hydroxyphthioceranoic chain that constitutes SL-II, the high mass end ion of *m/z* 2795.5 was subjected to CID. Again, the MS² spectrum of *m/z* 2795.5 (Figure S3a) contained the homologous ions at *m/z* 2102.8 and 2060.7, arising from losses of C₄₆⁻ and C₄₉-hydroxyphthioceranoic acids, respectively, together with the ions at *m/z* 1776 and 1818 arising from further loss of 18:0-fatty acid. MS³ on the ion of *m/z* 1776 (2795.5 → 1776; Figure S3b) gave rise to the ion-pair at *m/z* 1041/1083 by loss of C₄₉⁻/C₄₆⁻ hydroxyphthioceranoic acid, consistent with the observation of the C₄₉⁻ and C₄₆⁻ hydroxyphthioceranoic acid anions at *m/z* 733 and 691. The spectrum also contained the 6'-C₄₉⁻, or 6'-C₄₆-hydroxyphthioceranyl-glucose-2'-sulfate anions at *m/z* 957 and 915, indicating that the ion represents the major [18:0, hC₄₉, hC₄₉, hC₄₆]-SL and [18:0, hC₄₉, hC₄₆, hC₄₉]-SL isomers. The MS³ spectrum of the ion of *m/z* 1818 (2795.5 → 1818; Figure S3c) is dominated by the ion-pair of *m/z* 1083/1083 arising from elimination of 6-C₄₉/6'-

C₄₉-hydroxyphthioceranoic acid, indicating the presence of [18:0, hC₄₆, hC₄₉, hC₄₉]-SL isomer. The spectrum (Figure S3c) also contained the 1125/1041 ion-pair arising from further losses of C₄₆/C₅₂-hydroxyphthioceranoic acid, indicating the presence of the minor [18:0, hC₄₆, hC₄₆, hC₅₂]-SL isomer. The presence of this minor isomer is consistent with the observation of the ion at *m/z* 775 and 691 (Figure S3c). The ion of *m/z* 775 represents a 2,4,6,8,10,12,14,16,18,20,22,24-Dodecamethyl-22-hydroxytetracontanoic anion possessing 11 isopropyl repeat units, which is 1 isopropyl units longer than the that previously reported by Goren (4).

Characterization of the multiple methyl-branched hydroxyphthioceranoic acid

Upon subjected to ESI with skimmer CID (100 V), the SL extract yielded a whole array of anions in the mass range from *m/z* 383 to 775, corresponding to the [M – H][–] ions of hydroxyphthioceranoic and of phthioceranoic acids (Table 2). Elemental compositions deduced from high resolution mass measurements confirmed the presence of the major hydroxyphthioceranoic acid ion series at *m/z* 383, 397, ..., 607, ..., and 775, together with the minor phthioceranoic acid ion series at *m/z* 409, 423, ..., 591, ... and 703 (Table 2). The summed % of the ion abundance (Σ %) of the hydroxyphthioceranoic acid ion series is 88%; and that of the phthioceranoic acid ion series is 12%. These data gave the molar ratio of SL-II to SL-I close to 2/1, based on that SL-II consists of 3 hydroxyphthioceranoic acid residues and SL-I consists of 2 hydroxyphthioceranoic acid and one phthioceranoic acid residues, and both the hydroxyphthioceranoic and phthioceranoic acid residues were cleaved by skimmer CID in the same manner. These results further support the notion that the principal sulfolipid from H37Rv is SL-II; and SL-I is the minor component (Figure 2 and Table S1). The ion at *m/z* 607 is predominant (100%; Table 3), consistent with the earlier report that the major hydroxyphthioceranoic acid in SLs is a 2,4,6,8,10,12,14,16-Octamethyl-17-hydroxydotriacontanoic acid (4). The characterization of the structure of hydroxydotriacontanoic acids using MSⁿ and high-resolution mass spectrometry is described below.

The MS² spectrum of the ion of *m/z* 607 generated by skimmer CID on the sulfolipid mixture (Figure 5a) is identical to the MS³ spectrum of the ion of *m/z* 607 (2459 → 607; not shown) arising from dissociation of *m/z* 2459 (in this acquisition, the Q value of the ion-trap for MS² experiment was set to 0.2 to trap *m/z* 607 ion for further dissociation using MS³). The spectrum (Figure 5a) contained the ion at *m/z* 395, arising from elimination of the C₁₅H₃₂ residue by cleavage of the C-C bond next to the hydroxyl group distal to the carboxylate terminal, together with the ion at *m/z* 367 by loss of a C₁₅H₃₁CHO residue via cleavage of the C-C bond flank to the hydroxyl group vicinity to the carboxylate group. The cleavage of this latter bond is consistent with the observation of the ion of *m/z* 239, representing the deprotonated ion of C₁₅H₃₁CHO (i.e., C₁₄H₂₉CH=CH-O[–] ion) (Scheme 2). The spectrum also contained the ion at *m/z* 267, arising from cleavage of the C-C bond bearing the methyl branch foremost distal to the carboxylate terminal. The above structural information suggests the presence of a hydroxyl group at C-17. The predominant ions at *m/z* 605, 589 arose from losses of H₂, and of H₂O, respectively; while the ion at *m/z* 561 arose from further loss of CO₂ from *m/z* 605 and gave rise to the ion of *m/z* 349 by further elimination of a C₁₅H₃₂ residue. This fragmentation process is further supported by the MS⁴ spectrum of the ions of *m/z* 605 (Figure 5b) and 561 (data not shown). The ion at *m/z* 351 (607 - C₁₅H₃₂ - CO₂) may arise from primary loss of a C₁₅H₃₂ residue followed by further losses of CO₂ (Scheme 2). The assignments of the fragment ions were further supported by the elemental compositions deduced from high-resolution mass measurements (data not shown). The results are consistent with structural assignment of 2,4,6,8,10,12,14,16-Octamethyl-17-hydroxydotriacontanoic acid previously defined by Goren et al (4).

The MS² spectrum of m/z 649 (also generated from skimmer CID) and MS³ spectrum of the ion at m/z 649 (2459 → 649; Figure 5c) are identical and contained the ions at m/z 437, 391, and 393, which are 42 Da (C₃H₆) heavier than the analogous ions at m/z 395, 349 and 351 seen in Figure 5a, indicating the presence of an additional isopropyl group along the fatty acyl chain. The spectrum also contained the ions at m/z 239 and 267, indicating the presence of the same C₁₅H₃₁ terminal group, together with the ions at m/z 647 (649 – H₂), 631 (649 – H₂O), and 603 (647 – CO₂) that are analogous to ions at m/z 605, 589, 561 as seen in Figure 5a. The results indicate that the ion at m/z 649 represents a deprotonated 2,4,6,8,10,12,14,16,18-Nonamethyl-19-hydroxytetracontanoic acid anion. Similar mass shifts of the analogous ions were also seen in the MS³ spectra of the ion of m/z 691 (2543 → 691) and of m/z 733 (2795 → 733) (Scheme 2), suggesting the presence of the structures of 2,4,6,8,10,12,14,16,18, 20-Decamethyl-21-hydroxyhexatriacontanoic acid and 2,4,6,8,10,12,14,16,18, 20, 22-Undecamethyl-23-hydroxyoctatriacontanoic acid, respectively. The observation of the ion series of m/z 397, 439, 481, 523, 565, 607, 649, 691, 735, and 775 (Table 2) is in agreement with the suggested structures of [–]OOC-CH(CH₃)-(CH₂CHCH₃)_nCH(OH)C₁₅H₃₁ (n = 2-11) for hydroxyphthioceranoic acids. The presence of the C₂₅-hydroxyphthioceranoic acid at m/z 397 (n=2), and the C₅₂-hydroxyphthioceranoic acid at m/z 775 (n=11) are consistent with the observation of these two ions in the earlier structural assignment for the SL-II species of m/z 2122 (Figure S2) and 2795 (Figure S3), respectively.

Again, MS² and MS³ on the ion of m/z 635 (2543 → 635; Figure 5d) yielded ions analogous to those seen in Figure 5a-5c. The spectrum contained the ions at m/z 395, 351 and 349, identical to those seen in Figure 5a. However, the ions at m/z 267 and 295 are 28 Da heavier than the analogous ions at m/z 239 and 267 (Scheme 2) seen in Figure 5a. The results indicate the presence of the structure of 2,4,6,8,10,12,14,16-Octamethyl-17-hydroxyditriacontanoic acid, in which a terminal C₁₇H₃₅ rather than a C₁₅H₃₁ residue was attached to the same carbon that possesses the hydroxyl group. The homologous ions were seen at m/z 425, 467, 509, 551, 593, 635, 677, and 719, representing the ion series possessing the [–]OOC-CH(CH₃)-(CH₂CHCH₃)_nCH(OH)C₁₇H₃₅ structure, in which the homologous hydroxyphthioceranoic acids (n= 3-9) differed by a repeat C₃ (isopropyl) unit are present, in agreement with the previous findings (4).

Conclusions

Using high-resolution LIT MSⁿ, we made assignment of the complex structures of sulfolipids of *M. tuberculosis* H37Rv and confirm that SL-II not SL-I predominates the sulfolipid family, similar to the recent report by Layre et al who used a different approach (21). Thus, care should be taken when referring to the molecular structures of the major SL families as not to mis-assign the structures, if Goren's original designations of the SL families are to be followed. We verified that differences in culture media or extraction methods would not account for differences in the relative abundance of SL-I and SL-II. In all culture conditions tested, SL-II is always more abundant than SL-I; and extraction with decylamine in hexane was more efficient for extracting the SL families. We also revealed the detailed structures of each of the SL-II species, of which many isomers arising not only from the presence of the stearyl or palmitoyl at 2-position, but also from the various combinations of different chain lengths of the hydroxyphthioceranoic acid substituents located at 6- and 6'-position of the trehalose backbone. Thus, hundreds of structures are present for the entire SL-II family. This immense structure diversity has not been reported previously; and was seen in other important lipid families such as mycolic acids, phosphatidylinositol mannosides and trehalose dimycolates in our recent studies (22-24).

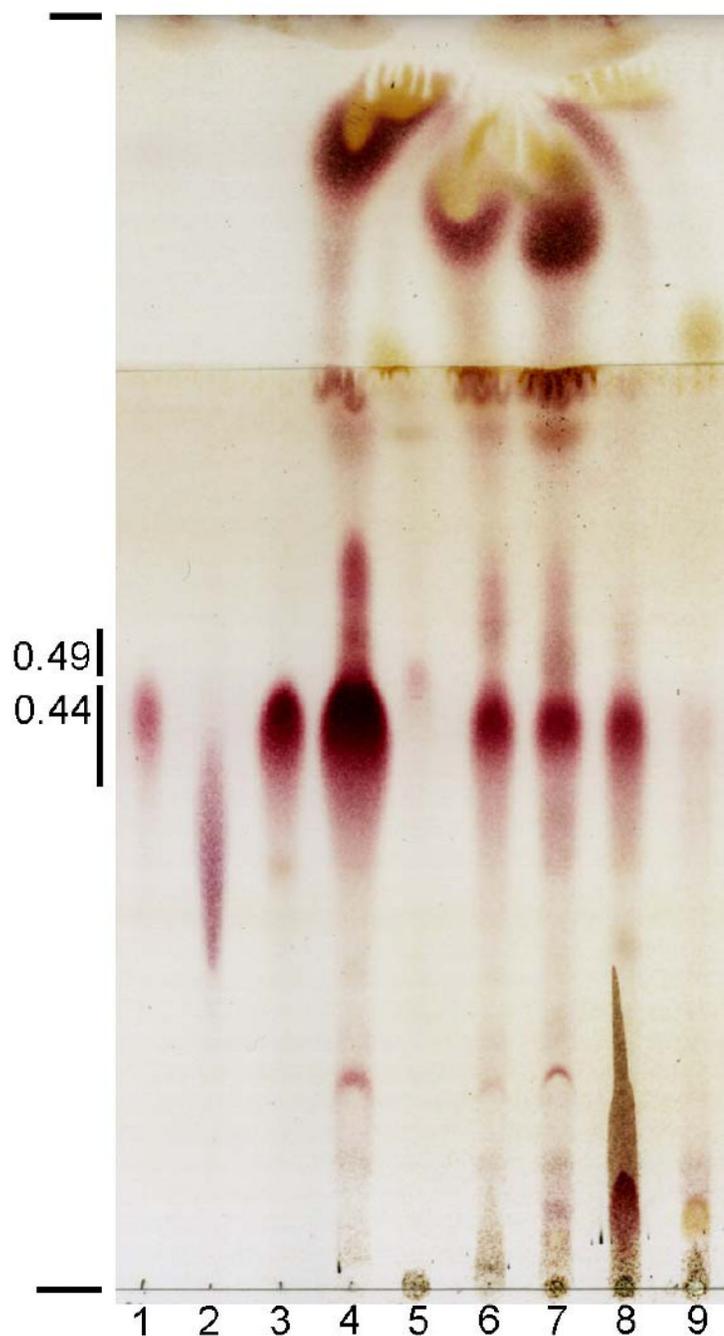

Figure 1.

TLC comparison of crude lipid extracts from *M. tuberculosis* H37Rv. Purified standards or crude lipids that were obtained under various conditions were spotted and developed in two solvents in the same direction. Standards, samples and the conditions that they were obtained with (if known) are indicated. Lane 1-SL-I standard from the CSU TB materials research contract (GAS broth; chloroform/methanol extraction (C/M)); lane 2-trehalose dimycolate standard from Sigma-Aldrich; lane 3-purified major SL (GAS broth; C/M); lane 4-crude lipids (7H10 plates, hexane-decylamine extract (HD)); lanes 5 and 6-crude lipids from different cultures (7H9 broth, HD); lane 7-crude lipids (Wong-Weinzirl broth, HD); lane 8-crude lipids (7H10 plates, C/M), and lane 9-crude lipids (7H9 broth, C/M). The

average R_f s of the SL families are indicated as well as the origin and the farthest solvent front.

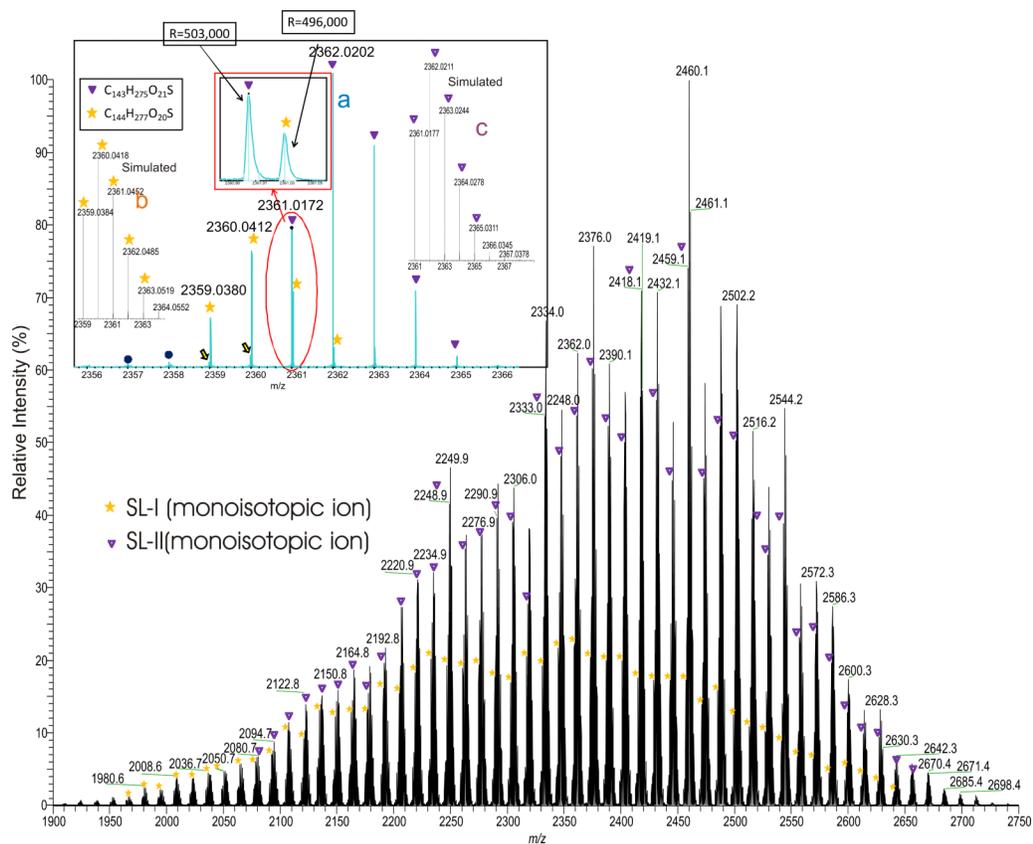

Figure 2. The high resolution ESI-MS spectrum of the $[M - H]^-$ ions of sulfolipids of H37Rv grown in Middlebrook 7H9 broth. The spectrum was obtained with a FTICR instrument. The high resolution ($R=500,000$) readily separated the SL-I (monoisotopic ions marked with “*”) class from SL-II (monoisotopic ions marked with “▼”), which is the principal sulfolipid class from *M. tuberculosis* strain H37Rv (inset). The elemental compositions deduced from accurate mass measurements also define SL-I and SL-II.

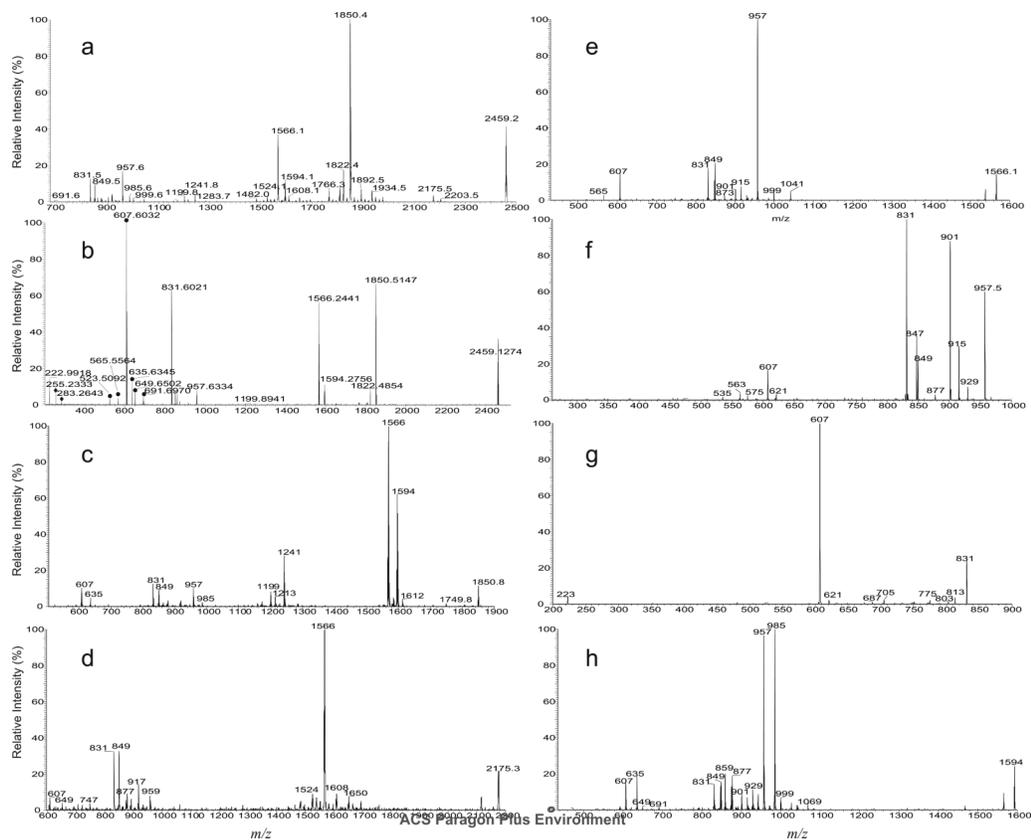

Figure 3.

The LIT CID MS² spectrum (a), and high-resolution HCD MS² spectrum (b) of the ion of m/z 2459. The low-mass fragment ions from HCD MS² (b) readily identify the hydroxyphthioceranoic acid (●), long chain fatty acid (◆) and sulfate groups (seen at m/z 222.9918); while the LIT CID MS³ spectra of m/z 1850 ($2459 \rightarrow 1850$) (c), 2178 ($2459 \rightarrow 2178$) (d), 1566 ($2459 \rightarrow 1566$) (e), and MS⁴ spectra of m/z 957 ($2459 \rightarrow 1566 \rightarrow 957$) (f), and of 831 ($2459 \rightarrow 1566 \rightarrow 831$) (g) together with the MS³ spectrum of m/z 1594 ($2459 \rightarrow 1594$) (h) support the fragmentation processes as illustrated in Scheme 1.

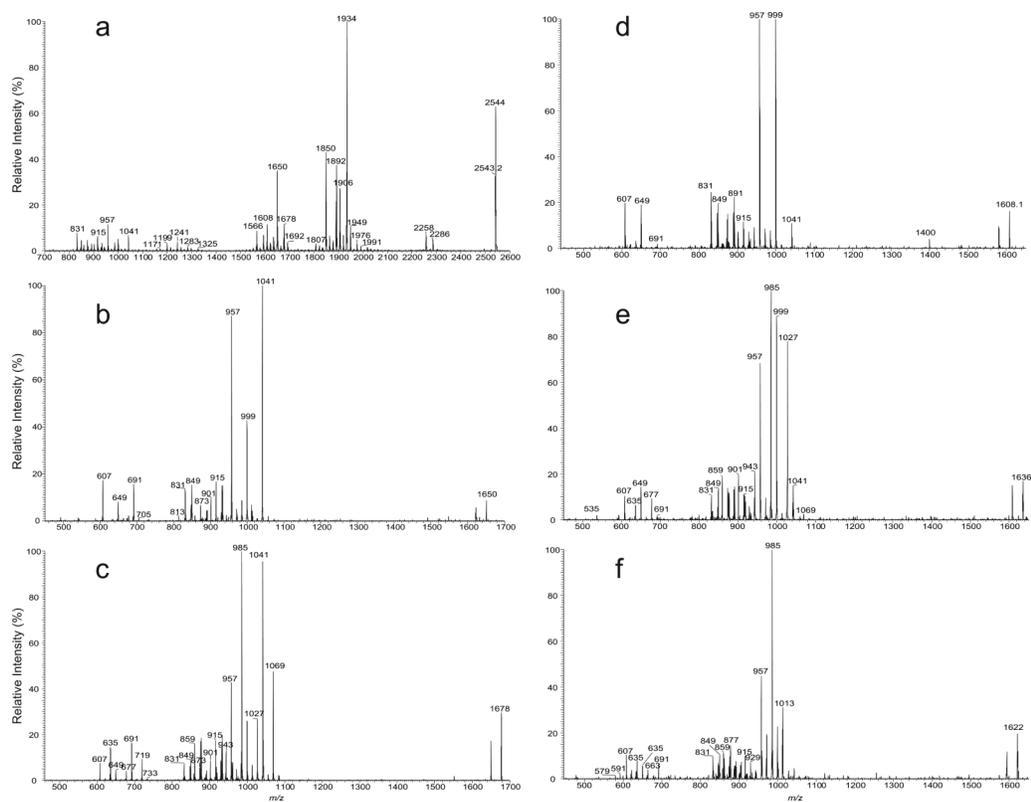

Figure 4. The LIT CID MS² spectrum of the ion of m/z 2543 (a), the sequential MS³ spectra of the ions of m/z 1650 (2543 \rightarrow 1650) (b), 1678 (2543 \rightarrow 1678) (c), 1608 (2543 \rightarrow 1608) (d), m/z 1636 (2543 \rightarrow 1636) (e), and of 1622 (2543 \rightarrow 1622) (f).

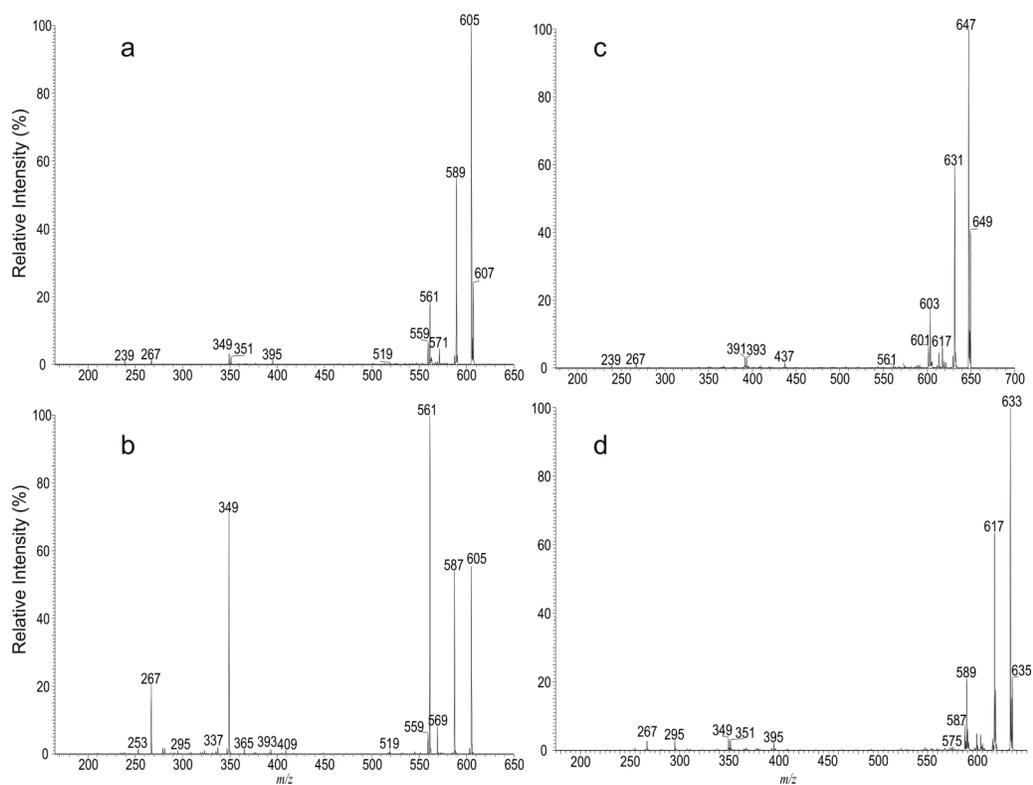

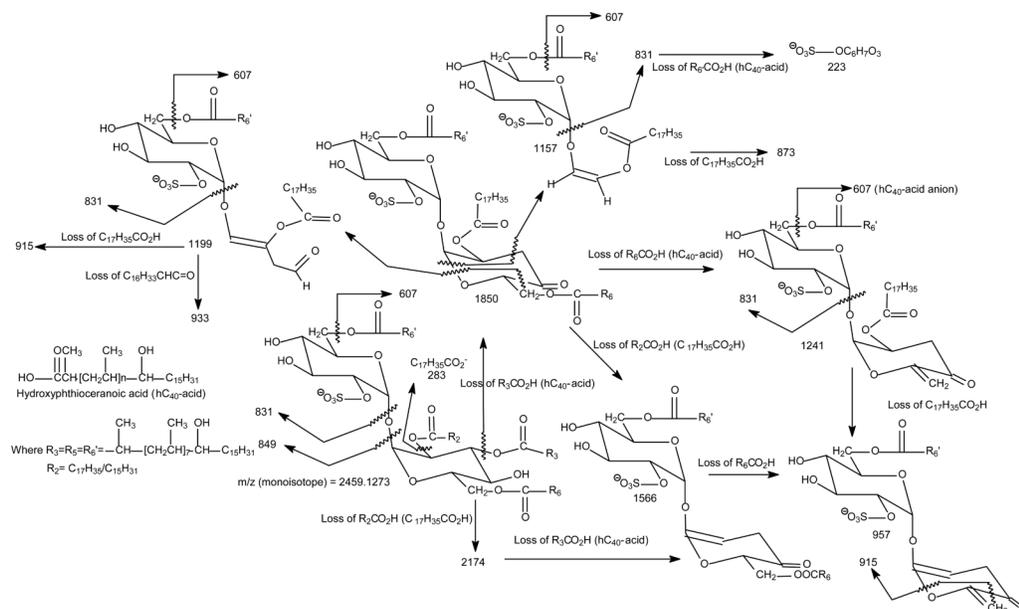

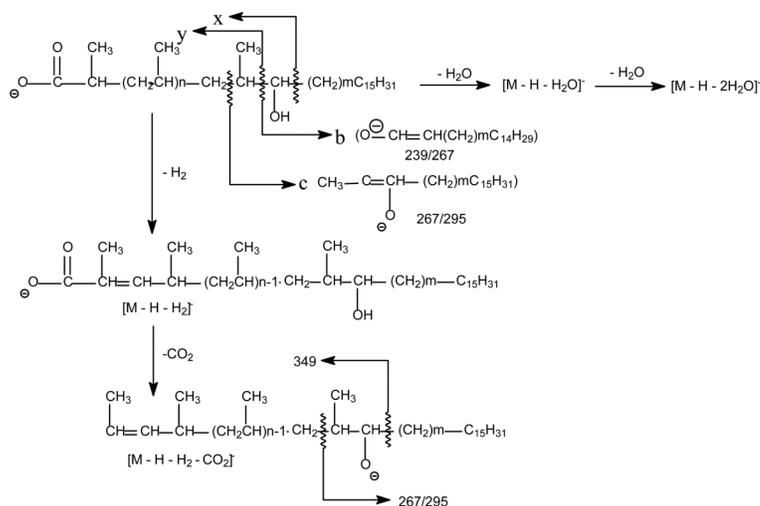

Figure 5. The CID MS² spectrum of the $[M - H]^-$ ion of C₄₀-hydroxyphthioceranoic acid at m/z 607 generated by skimmer CID (a), its MS³ spectrum at m/z 605 ($607 \rightarrow 605$) (b), and the MS³ spectra of the C₄₃-hydroxyphthioceranoic ion at m/z 649 ($2459 \rightarrow 649$) (c), and of the C₄₂-hydroxyphthioceranoic ion at m/z 635 ($2543 \rightarrow 635$) (d).

Scheme 1.

The fragmentation processes proposed for 2,3,6,6'-Tetraacyl- α,α' -D-trehalose 2'-sulfate (Sulfolipid II). Example shown is the pathways for the most prominent $[M-H]^-$ ion of m/z 2459 (monoisotopic) mainly representing a [18:0, hC40, hC40, hC40]-SL. The structures of the indicated fragment ions are supported by the elemental compositions deduced from accurate mass measurements with high-resolution MSⁿ mass spectrometry (See Table 1).

m	n	[M - H] ⁻	[M-H-H ₂] ⁻	[M-H-H ₂ O] ⁻	[M-H-2H ₂ O] ⁻	[M-H-H ₂ -CO ₂] ⁻	x	y	b	c	x-CO ₂	x-H ₂ -CO ₂
0	7	607	605	589	571	561	395	367	239	267	351	349
0	8	649	647	631	613	603	437	409	239	267	393	391
0	9	691	689	673	655	645	479	451	239	267	435	433
0	10	733	731	715	697	687	493	465	239	267	477	475
2	7	635	633	617	599	589	395	367	267	295	351	349

Scheme 2.

The fragment ions observed in the MSⁿ spectra of the major hydroxyphthioceranoic acid substituents in SL-II and the proposed fragmentation pathways leading to the ion formation and structure identification. The structures of the indicated fragment ions are supported by high-resolution LIT MSⁿ experiments (data not shown).

Table 1

The elemental composition of the fragment ions obtained from high-resolution CID and HCD MS² on [M – H][–] ion of sulfolipid of m/z 2459

nominal mass (m/z)	measured mass (Da)	calculated mass (Da)	elementary composition	nominal mass (m/z)	measured mass (Da)	calculated mass (Da)	elementary composition
