ABSTRACT

We have determined the nucleotide sequence of the *uvsX* gene of bacteriophage T4 which is involved in DNA recombination and damage repair, and whose product catalyzes *in vitro* reactions related to recombination process in analogous manners to *E. coli recA* gene product. The coding region consisted of 1170 nucleotides directing the synthesis of a polypeptide of 390 amino acids in length with a calculated molecular weight of 43,760. Amino acid composition, the sequence of seven NH₂-terminal amino acids and molecular weight of the protein deduced from the nucleotide sequence were consistent with the data from the analysis of the purified *uvsX* protein. The nucleotide sequence and the deduced amino acid sequence were compared with those of the *recA* gene. Although a significant homology was not found in the nucleotide sequences, the amino acid sequences included 23% of identical and 15% of conservatively substituted residues.

INTRODUCTION

The *uvsX* gene is dispensable for T4 phage multiplication in ordinary laboratory strains of *E. coli*, but plays important roles in genetic recombination, DNA repair and replication (1-3). We have purified *uvsX* protein to near homogeneity. The purified gene product catalyzed *in vitro* reactions related to general recombination (4) as *recA* protein of *E. coli* (5-10). These include single stranded DNA dependent hydrolysis of ATP, stimulation of pairing of complementary single strands, D-loop formation and branch migration with a polarity. However, these proteins differ each other in some respects (4); for instance, *uvsX* protein had no proteolytic activity on *E. coli lexA* protein, which is cleaved by *recA* protein at a specific site and controls SOS-function of the cell (11), and there was no immunological cross-reaction between these proteins (4). In addition, electron microscopic observation has revealed that these proteins cooperatively bind to double stranded DNA, but *uvsX* protein does not extend the DNA as *recA* protein does (12).

We have determined the nucleotide sequences of the *uvsX* gene and its

flanking regions, and deduced amino acid sequence of the gene product. We also compared these sequences with those of the recA gene and its product.

MATERIALS AND METHODS

Bacteria, phages and plasmids

E. coli ED8689 (hsdR⁻, su⁻) and T4dC mutant (42⁻ 56⁻ denB unf) were received from Dr. H. Takahashi (Tokyo Univ.) (13). An amber mutant in uvsX gene (amxb) was described previously (14). Amber mutants in genes 40 (amF12) and 41 (amN81) were from Dr. L. Black (Univ. Maryl. Sch. Med.) and our laboratory stock, respectively. A plasmid, pBR325 (15) was provided by Dr. A. Oka (Res. Fac. Nucl. Acid) and the expression vectors, pNT204 and pNT45 (16) were a gift from Dr. M. Imai (Inst. Virus Res.)

Preparation and manipulation of DNA

Purification of plasmids and M13 RFI DNA, gel electrophoresis and other recombinant DNA techniques were done as described by Maniatis et al. (17). Restriction enzymes were obtained from Takara Co. and used as described by the supplier.

Marker rescue experiment

The method is described in a previous paper (18). Briefly, suspensions of candidate clones were transferred onto plate which had been seeded with a mixture of ED cells and UV-killed amxb.

DNA sequencing

DNA sequencing was done by the dideoxy method of Sanger et al. (19) on fragments cloned into M13mp18 or M13mp19 (20) using Takara's DNA sequencing kit.

Purification of uvsX protein

The purification of uvsX protein has been described (4).

SDS-polyacrylamide gel electrophoresis

Cells in 0.2 ml of culture were pelleted and dissolved in 40 μ l of SDS-gel electrophoresis sample buffer and boiled for 2 min. Proteins were separated by electrophoresis on SDS-polyacrylamide slab gels (21) and the gels were stained with Coomassie brilliant blue.

RESULTS AND DISCUSSION

Cloning of T4 uvsX gene

Comparing the T4 physical map (22) and the genetic map around the uvsX gene (2, 23), we assumed the gene would be located on a fragment of about 3kb EcoRI digest. T4dC DNA was digested with EcoRI and electrophoresed on a

Fig. 1. Cleavage maps and sequencing strategy of the *uvsX* gene and its flanking regions. (A) The position of *uvsX* gene (boxed) in the T4 physical map (22). (B) The restriction map of the 3 kb *Eco* fragment. *Tag*I sites are indicated by vertical lines. (C) The sequenced fragments. The directions and the extents of the sequence determinations are shown by arrows.

1% agarose gel. The bands of about 3 kb were eluted and cloned into the *Eco*RI site on the *Cm* gene of pBR325. *Amp*^R *Cm*^S clones were collected and screened by a marker rescue test with UV-irradiated *amx*b as described in Materials and Methods. pBSK101, a plasmid thus isolated, contained an *Eco*RI fragment with an estimated size of 3.43 kb (3 kb *Eco* fragment). The plasmid also rescued *amF12* (40⁻) but not *amN81* (41⁻). Mattson *et al.* (24) reported another *Eco*RI fragment which rescued *tsL84* (40⁻), *amN57*, *amA461* and *amH601* (41⁻). These observations suggest that an *Eco*RI site exists in gene 40, which is split, upon *Eco*RI digestion, into two fragments; the 3kb *Eco* fragment and the fragment reported by Mattson *et al.* (24). Fig. 1 shows a physical map of the 3 kb *Eco* fragment, corresponding to 21.15 through 24.38 units in the T4 map (22).

Confirmation of *uvsX* gene on the 3kb *Eco* fragment

We have proved the presence of the entire *uvsX* gene sequence in the 3 kb *Eco* fragment by cloning the fragment into the expression vector pNT45, a derivative of pBR322 which carries the major leftward promoter (P_L) of lambda. In bacterial strains carrying pNT204, which harbors the temperature sensitive lambda repressor gene, *ci857*, temperature dependent expression of genes inserted downstream of the P_L promoter has been shown to occur (16). *Amp*^R transformants were isolated, followed by screening with marker rescue

Fig. 2. Overexpression of uvsX gene. (A) Cells were grown at 30°C and shifted to 42°C. Samples were taken at indicated times after the shift, pelleted and dissolved in SDS-sample buffer, followed by electrophoresis in SDS-polyacrylamide gels as described in Materials and Methods. (B) Purified uvsX protein from phage infected cells (lane 1) and induced cells (lane 2) were subjected to SDS-polyacrylamide gel electrophoresis.

of a UV-irradiated T4 uvsX mutant. Several candidate clones carrying the uvsX gene were transferred to 42°C to derepress the P_L promoter. At various times after the temperature shift, cells were collected and total cell proteins were analyzed by SDS-polyacrylamide gel electrophoresis (Fig. 2A). About a half of clones showed a dramatic increase in the amount of proteins in two bands, the larger one of which had a molecular weight identical to that previously determined for uvsX protein (4). The overproduced protein was purified to near homogeneity (Fig. 2B). The overall yield was 10 mg from 1 g (wet weight) cells . The purified protein

Fig. 3. Nucleotide sequences of the *uvsX* gene and its flanking regions. The initiation codon (ATG) and two termination codons (TAA, TGA) are boxed. The Shine-Dalgarno sequence is indicated by a wavy line. The putative -10 and -35 promoter sequences are indicated by a double line and an underline, respectively. A palindromic sequence is indicated by arrows. The predicted amino acid sequence is shown under the nucleotide sequence. A dashed underline indicates the amino acid sequence confirmed by protein sequencing.

showed the same specific activity in hydrolysis of ATP to ADP + Pi (T. Shibata, personal communication), D-loop formation and branch migration as *uvsX* protein purified from phage-infected cells (data not shown).

Nucleotide sequences of the *uvsX* gene and its flanking regions

The sequencing strategy is shown in Fig. 1C. The 3kb *Eco* fragment was digested with *Bgl*II and *Pst*I, and the resulting three fragments were separated by agarose gel electrophoresis. Each fragment was digested with *Tag*I and cloned into M13mpl8 or M13mpl9. DNA sequences of the cloned fragments were determined by the dideoxy method of Sanger *et al.* (19). Nucleotide sequences of an open reading frame coding for a polypeptide of 390 amino acid residues, corresponding to the *uvsX* gene as described below,

Table 1 Amino Acid Composition of uvsX protein

Val	24	26

and its flanking regions are presented in Fig. 3.

To show that the open reading frame encodes the uvsX gene, the amino acid sequence of the seven residues from the NH₂ terminus of the uvsX protein isolated from T4-infected cells was determined. The sequence was NH₂-Ser-Asp-Leu-Lys-Ser-Arg-Leu, in perfect agreement with the sequence predicted from the nucleotide sequence, except for the absence of the Met residue at the NH₂ terminus. The amino acid composition of the purified uvsX protein is also in good agreement with the composition of the protein predicted from the nucleotide sequence (Table 1). The molecular weight of uvsX protein deduced from the nucleotide sequence is 43,760 in the absence of the initiating Met residue. This is in reasonable agreement with the molecular weight of 39,000 which was estimated by SDS-polyacrylamide gel electrophoresis (4). From these facts, we conclude the sequence codes for uvsX gene.

The initiation ATG codon (boxed) of the uvsX gene is preceded by a Shine-Dalgarno sequence (wavy lined), a ribosome binding site, at an appropriate distance. Consensus promoter sequences, the putative -35 (underlined) and -10 (doubly lined) sequences were found at about 200 bp upstream from the ATG codon. The putative -35 sequence is consistent to the middle promoter of T4, which requires the mot gene product of T4 for

Fig. 4. Amino acid sequences of *uvsX* and *recA* proteins. The *recA* protein sequence (upper line) is described by Horii et al. (32) and Sancar et al. (33); the *uvsX* protein sequence (lower line) is determined in this paper. Identities (dotted) and conservative substitutions are boxed. The common sequence in ATP binding sites is indicated by a double line.

expression (25). Interestingly, the *uvsX* gene has two overlapped -35 middle promoter sequences. There is no direct evidence that the synthesis of *uvsX* protein depends on the *mot* protein, but kinetic study of the incorporation of ^3H -leucine into proteins indicated that the synthesis was not immediate early but delayed early (14). There are two tandemly aligned termination codons, TAA and TGA (boxed), which are followed by a stem- and loop-sequence rich in GC (arrowed).

Structure of *uvsX* protein

The protein has a Tyr-rich region between residues 76 and 99 where four Tyr residues are occurring at 4 to 10 residue intervals, and its COOH-terminal region (residues 374 to 390) is rich in acidic residues. These features are common among single stranded DNA binding proteins from various sources (26-30). However, it should be noted that unlike other single stranded DNA binding proteins the single stranded DNA-*uvsX* protein complex is extremely unstable at physiological temperature (unpublished). Walker et al. (31) suggested sequences common to ATP binding sites among ATPases. One of them, Gly-X-X-X-hydrophobic-hydrophobic-hydrophobic-hydrophobic-Asp is present in *uvsX* protein (residues 135 to 143).

Comparison of the nucleotide and amino acid sequences of *uvsX* and those of *recA*.

As mentioned in Introduction, *uvsX* and *recA* proteins play a pivotal role in recombination and catalyze several common *in vitro* reactions. We compared the nucleotide sequences of genes *uvsX* and *recA*, the latter having been determined by Horii *et al.* (32) and Sancar *et al.* (33). No significant homology in nucleotide sequences was found between these genes. The amino acid sequences of the *uvsX* and *recA* proteins are aligned to get good matches as shown in Fig. 3, although any alignment of two proteins will show some accidental homology as pointed out by Doolittle (34). Approximately, 23 % of amino acid residues along the sequences is identical each other and a further 15 % is conservatively (35) substituted. The conserved sequence proposed for the ATP-binding site of ATPases is found at the similar position from the NH₂ terminus, starting at residue 135 of *uvsX* protein and at residue 137 of *recA* protein. In addition, the amino acid sequences of the flanking regions of the ATP-binding site are considerably conserved; 50% in 50 residues on the NH₂ terminal side and 53% in 14 residues on the COOH terminal side. The COOH-terminal regions of two proteins are rich in acidic residues as commonly observed in DNA-binding proteins. However, in *recA* protein there is no Tyr-rich region at the corresponding position of *uvsX* protein. Further analysis and comparison of the structure and functions of these proteins would provide information necessary to understand the essential structure of recombination protein.

ACKNOWLEDGMENTS

We give special thanks to Dr. K. Wada (Osaka Univ.) for determining the NH₂ terminal amino acid sequence and the amino acid composition of the *uvsX* protein. We thank Dr. M. Takanami for advices on DNA sequencing, Dr. Y. Shimura for critical reading of the manuscript and Dr. Y. Ryo for valuable discussion. This work was supported by a grant-in-aid for Scientific Research from the Ministry of Education, Science, and Culture of Japan.
