Abstract

Peroxidation of cardiolipin in mitochondria is essential for the execution of apoptosis. We suggested that integration of oleic acid into cardiolipin generates non-oxidizable cardiolipin species hence protects cells against apoptosis. We synthesized mitochondria-targeted triphenylphosphonium oleic acid ester. Using lipidomics analysis we found that pretreatment of mouse embryonic cells with triphenylphosphonium oleic acid ester resulted in decreased contents of polyunsaturated cardiolipins and elevation of its species containing oleic acid residues. This caused suppression of apoptosis induced by actinomycin D. Triacsin C, an inhibitor of acyl-CoA synthase, blocked integration of oleic acid into cardiolipin and restored cell sensitivity to apoptosis.

Keywords

Cardiolipin; apoptosis; mitochondria; cardiolipin remodeling; cardiolipin oxidation; mitochondria-targeted triphenylphosphonium oleic acid ester

1. Introduction

Cardiolipin (CL) is a mitochondria-specific doubly charged anionic phospholipid with four fatty acid residues [1]. In normal cells, it is exclusively localized to the inner mitochondrial membrane (IMM) where it accounts for ~25% of all phospholipids [2]. CL is synthesized on

the matrix side of the IMM [3,4] as a premature form that is deacylated by phospholipases A to generate monolyso-CL [5,6,7]. The latter can be re-acylated by tafazzin, a mitochondrial phospholipid trans-acylase [6,8] predominantly present in the IMM [9], to yield mature species of CL [10]. In addition, mitochondria contain a coenzyme A-(CoA)-dependent acyltransferase, mono-lyso-CL acyltransferase (MLCL AT), that acylates monolyso-CL to CL [11]. Finally, endoplasmic reticulum (ER) acyl-CoA lyso-CL acyltransferase-1 (ALCAT 1), known to be upregulated by oxidative stress [12,13], can also catalyze synthesis of polyunsaturated CL species [14].

In addition to CL's multiple structural and signaling functions in normal cell physiology, it is also an important player in apoptotic cell death pathways. Changes of the CL content and oxidation status have been associated with the execution of extrinsic and intrinsic apoptosis [15,16]. The early stage of intrinsic apoptosis is characterized by the formation of CL/cytochrome c (cyt c) complexes in mitochondria that exhibit a potent peroxidase activity towards polyunsaturated CL [17]. Polyunsaturated species of CL have been identified as a preferred oxidation substrate of cyt c catalyzed reactions *in vitro* [18,19] and *in vivo* [20,21,22,23]. Accumulation of CL oxidation products in mitochondria of apoptotic cells has been found essential for the release of pro-apoptotic factors into the cytosol [17]. We suggested that integration of mono-unsaturated oleic acid residues into mitochondrial CL – via its remodeling pathways in mitochondria - will generate non-oxidizable CL species thus protecting cells against apoptosis. We synthesized a poorly-peroxidizable triphenylphosphonium (TPP) octadecaenoic acid (C_{18:1}) ester (TPP-C_{18:1}) and used it for targeted delivery into mitochondria of mouse embryonic cells (MEC). Using liquid chromatography/mass spectrometry (LC/MS) based lipidomics analysis we established that pro-apoptotic stimulation with actinomycin D (AcD) was accompanied by selective oxidative consumption of CL molecular species containing polyunsaturated octadecadienoic (C_{18:2}), eicosatetraenoic (C_{20:4}), and docosahexaenoic (C_{22:6}) acids. Pretreatment of MEC with TPP-C_{18:1} resulted in: i) significant decrease of CL polyunsaturated molecular species and simultaneous elevation of poorly-oxidizable CL molecular species containing C_{18:1} and ii) suppression of AcD induced apoptosis. An inhibitor of long chain acyl-CoA synthase (ACSL), triacsin C, blocked integration of C_{18:1} into CL molecules and restored MEC's sensitivity to AcD-induced apoptosis.

2. Methods

Synthesis of TPP-C_{18:1}

3-[(Z)-octadec-9-enoyl]oxypropyl-triphenyl-phosphonium chloride: A suspension of C_{18:1} (1 mmol) and silver nitrate (2 mmol) was stirred at 25 °C for 2 hrs. (3-bromopropyl)triphenylphosphonium bromide (1 mmol) was added and the reaction mixture was further stirred at 25 °C for 12 hrs. Thereafter, the mixture was filtered and the filtrate evaporated to dryness under reduced pressure. The remaining residue was re-dissolved in 50% methanol containing 1% NaHCO₃ and 1% NaCl. The TPP ester was extracted with ethyl acetate and the extract dried over Na₂SO₄. Evaporation of the organic solvent afforded 0.55 mmol of 3-[(Z)-octadec-9-enoyl]oxypropyl-triphenyl-phosphonium chloride (ESI-MS analysis revealed a single peak with m/z = 585.4).

Cell culture

Mouse embryonic cells (MEC) were grown in Dulbecco's Modified Eagle Medium containing 15% fetal bovine serum, 25 mM HEPES, 0.05 mg/ml uridine, 0.05mM 2-mercaptoethanol, 1x MEM (Invitrogen, Carlsbad, CA) and 100 U/ml penicillin/streptomycin in a humidified atmosphere (5% CO₂ plus 95% air). Cells were pretreated with TPP-C_{18:1} (1–50μM) at 37°C for 2 hrs and after that exposed to AcD (100 ng/ml) at 37°C for 16 hrs.

To block ASCL cells were treated with triacsin C (10 μ M) at 37°C for 30 min. Cell viability was measured using AlamarBlue assay (Invitrogen, Carlsbad, CA). Apoptosis was evaluated by phosphatidylserine (PS) externalization using Annexin V-FITC apoptosis detection kit (Biovision, Mountain View, CA) and caspase 3/7 with a luminescence Caspase-Glo™ 3/7 assay kit (Promega, Madison, WI).

Analysis of CL

Lipids were extracted using the Folch procedure [24]. Lipid phosphorus was determined by a micro-method [25]. LC/MS was performed using a Dionex Ultimate™ 3000 HPLC coupled on-line to a linear ion trap mass spectrometer (LXQ Thermo-Fisher) as described [21]. CL was separated by 2D-HPTLC [26] and fatty acids were analyzed by LC/MS after hydrolysis of CL with porcine pancreatic phospholipase A₂ (PLA₂) as described [21].

Analysis of TPP-C_{18:1}

Mitochondria were isolated from MEC treated with TPP-C_{18:1} (50 μ M, for 2h at 37°C) as described [27]. TPP-C_{18:1} was extracted from mitochondria by Folch procedure [24] and LC/MS in positive mode was performed using a Dionex Ultimate™ 3000 HPLC coupled on-line to a linear ion trap mass spectrometer (LXQ Thermo-Fisher). TPP-C_{18:1} and TPP were separated on a normal phase column (Luna 3 μ m Silica 100A, 150x2 mm, (Phenomenex, Torrance CA)) with flow rate 0.2 mL/min using gradient solvents containing 5 mM CH₃COONH₄ (A – n-hexane:2-propanol:water, 43:57:1 (v/v/v) and B - n-hexane:2-propanol:water, 43:57:10 (v/v/v)). At these conditions the retention times for TPP-C_{18:1} and TPP were 27.9 and 50.6 min, respectively.

Statistics

The results are presented as mean \pm S.E.M. values from at least three experiments, and statistical analyses were performed by either paired/unpaired Student's t-test or one-way ANOVA. The statistical significance of differences was set at $p < 0.05$

3. Results

AcD-induced apoptosis and oxidative consumption of CL in MEC

To avoid complications possibly associated with non-specific oxidative events commonly accompanying the execution of apoptotic program triggered by redox-cycling agents (eg, paraquat, tetracyclines antibiotics, quinones) as well as sources of oxidizing equivalents like H₂O₂ we used a known non-oxidant inducer of mitochondria-dependent intrinsic cell death pathway, AcD [28]. Accordingly, AcD induced apoptosis in MEC as evidenced by caspase 3/7 activation (Fig. 1Aa) and PS externalization (Fig. 1Ab). To assess the role of CL peroxidation in AcD-induced apoptosis we employed LC/MS analysis of CL molecular species. In a typical negative mode MS spectrum of CL from MECs, six clusters were detectable (Fig. 1Ba). Thirty six molecular species of CLs contained oxidizable polyunsaturated fatty acid residues [19]. We found a significant decrease in the amount of polyunsaturated CLs in cells challenged with AcD (vs control cells) – in line with likely peroxidative “consumption” of polyunsaturated molecular species of CL. The oxidation was selective: significant decreases of the contents occurred only in four molecular species of CL - with m/z 1448, m/z 1472, m/z 1494 and m/z 1496 - containing C_{18:2}, C_{20:4}, and C_{22:6} fatty acid residues and corresponding to (C_{18:2})₄, (C_{18:2})₃(C_{20:4}), (C_{18:2})₂(C_{20:4})₂ and (C_{18:2})₃(C_{22:6}), respectively (Fig. 2Bb). Quantitative assessment of oxidized CL revealed accumulation of oxidation products formed from these CL molecular species (Fig. 2Bc,d) that were represented by species containing 1–4 oxygens in their fatty acid residues (Fig. 2Bc, inserts).

Effect of TPP-C_{18:1} on AcD-induced apoptosis and CL oxidation in MEC

We reasoned that delivery of TPP-conjugated monounsaturated C_{18:1} into mitochondria would favor its integration into CL through acyl-CoA-dependent remodeling pathways by MLCL AT or ALCAT 1 [6,12,13]. Using an uncoupler might be diagnostic of potential-driven accumulation of TPP-C_{18:1} in mitochondria. However, experiments with uncouplers in cells are complicated by their cytotoxic effects. A recent study discovered another intricacy in interactions of TPP-based penetrating ions with anions of fatty acids that can act as mitochondria-targeted protonophorous uncouplers [29]. Therefore, we chose to employ LC/MS to assess the content of TPP-C_{18:1} and its de-esterified product, TPP, in mitochondria of cells exposed to TPP-C_{18:1}. Direct LC/MS analysis demonstrated the presence of TPP-C_{18:1} and its hydrolysis product, TPP in mitochondria of treated cells (Fig. 2a). Quantitative assessment revealed that the amount of TPP-C_{18:1} and TPP was 83.0 ± 5.2 and 41.0 ± 4.5 nmol/mg mitochondrial protein, respectively (Fig.2b). Given that accumulation of TPP-conjugated non-modified and modified fatty acids such as dodecyl-TPP, TPP-imidazole-substituted C_{18:0} and C_{18:1} in mitochondria has been demonstrated in previous studies [27,29] - it is conceivable, although still hypothetical, that TPP-C_{18:1} employed in the present work also accumulated in mitochondria.

Interestingly, LC/MS analysis of lipids in TPP-C_{18:1} treated MEC revealed significant decrease in the levels of exactly those CL species with polyunsaturated fatty acids (*m/z* 1448, *m/z* 1472, *m/z* 1494 and *m/z* 1496) that underwent oxidation in cells exposed to AcD. At the same time, the content of C_{18:1}-containing species of CL, particularly CL-(C_{18:1})₄ (*m/z* 1456) was markedly increased (Fig. 3Aab). In line with this, LC/MS analysis of fatty acids after CL hydrolysis by PLA₂ demonstrated the increase of C_{18:1} (Fig. 3Ac) and decrease of C_{18:2}, C_{20:4}, C_{20:3}, C_{22:6} and C_{22:5} fatty acid residues in CL molecules (Fig. 3Ad).

Assuming that CL peroxidation is essential for the execution of the mitochondrial segment of apoptotic program, TPP-C_{18:1} should exert anti-apoptotic effect. Indeed, treatment with TPP- C_{18:1} markedly increased resistance of MEC to AcD induced apoptosis as evidenced by inhibition of PS externalization (Fig. 3Ba) and caspase 3/7 activity (Fig.3Bb). In contrast, C_{18:1} without the TPP-moiety did not change cell viability and was not effective in suppression of apoptosis in these cells (data not shown). Importantly, the AcD-induced “oxidative consumption” of polyunsaturated CL molecular species was significantly less pronounced in cells pre-treated with TPP-C_{18:1} (Fig. 4A). These results indicate that selective CL remodeling leading to the accumulation of its non-peroxidizable species is associated with the protection of cells against AcD-induced apoptosis.

Effect of triacsin C on AcD-induced apoptosis and CL oxidation in TPP-C_{18:1} treated MEC

To further verify that CL remodeling is responsible for anti-apoptotic effect of TPP-C_{18:1}, we utilized triacsin C – an inhibitor of ACSL, an enzyme that generates acyl-CoAs [30]. We found that triacsin C treated cells exhibited high sensitivity to AcD-induced apoptosis and abolished the anti-apoptotic effect of TPP-C_{18:1} (Fig.4B). Neither significant enrichment of CL with C_{18:1} (Fig.4Cab) nor changes in CL oxidation (Fig. 4A) were detected in triacsin C treated/TPP- C_{18:1} exposed cells compared to control. Thus, CL re-acylation pathway – dependent on ACSL-driven formation of acyl-CoA - is the likely major contributor to the anti-apoptotic effect of TPP-C_{18:1} in MEC.

4. Discussion

MEC are commonly used as a normal cell culture model for studies of cell death pathways including apoptosis [31,32,33]. It has been demonstrated that MEC exhibit typical apoptotic features such as DNA fragmentation, PS externalization, caspase 3/7 activation as well as

cyt c release in response to different stimuli including AcD [17,19,34]. Because the goal of this work was to develop protective strategies against apoptosis, we chose to employ a model of normal, rather than tumor, cells for the current study.

Accumulation of CL oxidation products - predominantly CL-hydroperoxides - is a required early stage of apoptosis essential for the release of pro-apoptotic factors - including cyt c - from mitochondria into the cytosol [17]. This was uniformly characteristic of different pro-apoptotic stimuli in cultured cells *in vitro* [18,19] and several types of exposures *in vivo* such as total body irradiation [21,22], hyperoxia [20] and traumatic brain injury [23]. This CL and its peroxidation may act as a mitochondrial switch regulating sensitivity of cells to apoptosis [17] hence represent a new target for drug discovery. The peroxidation process is catalyzed by an intermembrane space protein of mitochondria - cyt c - that forms a high affinity peroxidase complex with polyunsaturated CLs [17]. Inhibitors of the peroxidase activity effective in suppressing CL peroxidation have been shown to exert potent anti-apoptotic effects [19,20,35]. Among those, mitochondria-targeted imidazole-substituted fatty acids displayed a potent anti-apoptotic effect *in vitro* and *in vivo* resulting in significant protection against acute radiation damage [27].

This work demonstrates, for the first time, that mitochondrial delivery of poorly peroxidizable mono-unsaturated TPP-C_{18:1} resulted in remodeling of endogenous pool of CLs such that CLs containing polyunsaturated fatty acid residues becomes less abundant while the content of C_{18:1}-containing species increased. This remodeling conferred increased resistance of MEC to AcD induced apoptosis. Given that saturated fatty acid residues do not undergo peroxidative modifications, they may represent an alternative group of compounds for CL remodeling with potential anti-apoptotic consequences. However, it has been reported that saturated fatty acids are poor substrates for CL reacylation reactions [13] and the rates of their turnover in CLs are very low [36].

The diversity of CLs is defined by two major metabolic pathways - its biosynthesis and remodeling. *De novo* synthesis via condensation of one molecule of phosphatidylglycerol and one molecule of cytidine-5'-diphosphate-1,2-diacylglycerol catalyzed by CL synthase (CLS1) takes place in mitochondria [3,4]. It is believed that *de novo* synthesis is responsible for non-specific diversification of CL molecular species while acyl-specific remodeling limits and fine-tunes the number of CL molecular species in different tissues [37]. At least three enzymes are involved in remodeling of CL. Tafazzin, a mitochondrial phospholipid transacylase - presents exclusively in the IMM [6,8,9] - transfers acyl residues, predominantly linoleic acid, from PC and PE into monolys-CL [38,39,40] independently of CoA [41]. CoA-dependent remodeling of CLs can occur in both mitochondria and ER [12,13]. It is catalyzed by MLCL AT and ALCAT 1 with high specificity towards poly- and monounsaturated fatty acids [13]. Both enzymes utilize acyl-CoA as a substrate in the reaction for acylation of mono-lyso-CL [11,13] and can be specifically down regulated through inhibition of ACSL by triascin C [30]. In line with this, our results demonstrated that triascin C effectively inhibited TPP-C_{18:1}-driven remodeling of CL in MEC. Notably, triascin C also restored sensitivity of TPP-C_{18:1}-supplemented cells to AcD-induced apoptosis suggesting that CoA-dependent remodeling is involved in modification of CL in MEC exposed to TPP-C_{18:1}. This is further supported by our oxidative lipidomics measurements which revealed that only four out of thirty six polyunsaturated molecular species of CL were selectively oxidized in MEC during apoptosis triggered by AcD. By metabolically manipulating these CL species and decreasing their susceptibility to peroxidation we were able to decrease the sensitivity of cells to apoptosis.

Our previous work established that by suppressing CLS1 by specific RNAi we were able to cause CL-deficiency, decrease CL peroxidation thus increase resistance of HeLa cells

challenged with AcD to apoptosis [28]. Here, we experimentally tested an alternative approach based on manipulations of CL oxidizability using poorly-oxidizable C_{18:1}. To minimize C_{18:1} toxicity and deliver C_{18:1} into cells and mitochondria without damaging them, we conjugated C_{18:1} with an organic cation TPP - commonly used for delivery of different payloads into mitochondria via “electrophoretic mechanism” based on negative inside mitochondrial membrane potential [42,43,44]. TPP conjugated fatty acids can be rapidly hydrolyzed intracellularly by esterases in mitochondria and ER [27]. Therefore, unesterified C_{18:1} can be quickly activated by ACSL that is present in the ER or mitochondria [45,46] to C_{18:1}-CoA and utilized for CL remodeling.

It is possible that enrichment of mitochondria with oleoyl-containing CL molecular species may affect interactions of this essential anionic phospholipid with a number of mitochondrial proteins such as cytochrome c oxidase [47,48], creatine kinase [49,50], ATP synthase [51,52], mitochondrial ADP carrier [53] resulting in altered functional status. Our previous work, however, demonstrated that depletion of 55% of endogenous CL in HeLa cells did not affect their growth rate, mitochondrial biomarker proteins and levels of ATP and mitochondrial membrane potential [28]. Further, cytochrome c binding constant for tetra-oleoyl-CL was similar to that of tetra-linoleoyl-CL [54].

In summary, we developed a new approach to regulate cell’s sensitivity to apoptosis via manipulations of their CL’s oxidizability. While our findings on regulation of sensitivity to apoptosis via manipulations of the CL’s oxidizability have been obtained using MEC as a normal cell culture model, we suggest that this approach may be applicable to other cell types as well. Indeed, oxygenation of CL molecular species during apoptosis of different normal primary cell cultures, including lung epithelial cells, lung endothelial cells, rat cortical neurons has been reported [18,20,21]. However, metabolic remodeling of CLs can be utilized as an effective tool not only for suppressing (by non-oxidizable fatty acid precursors) but also for enhancing (via highly oxidizable polyunsaturated fatty acid precursors) apoptotic death pathway. In this way, this approach can be utilized for the development of new therapeutic modalities to prevent excessive apoptosis or stimulate it in cancer cells.

Highlights

- Generation of non-oxidizable oleate-enriched cardiolipins via mitochondrial targeting
- Desensitization to apoptosis via suppression of cardiolipin oxidation
- Inhibition of long chain acyl-CoA synthase by triacsin C reinstates polyunsaturation of cardiolipin and sensitivity to apoptosis.

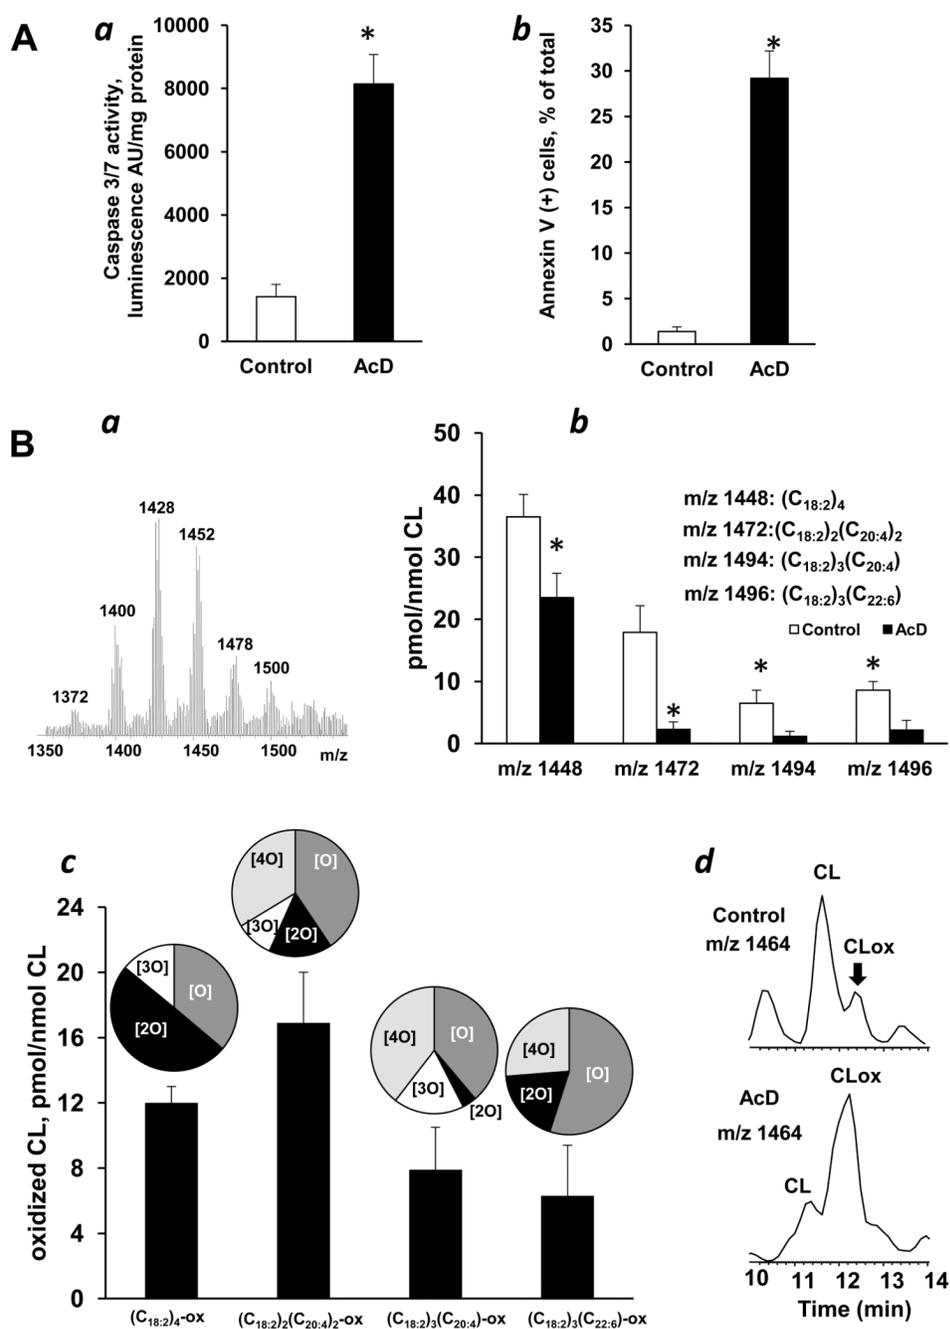

Figure 1. Apoptosis and CL oxidation induced by AcD in MEC

A - Apoptosis induced by AcD in MEC. (a) Caspase 3/7 activation and (b) PS externalization in MEC exposed to AcD (100 ng/ml). Data are means \pm S.E., $n=10$, * $p<0.05$ vs control. **B** - AcD-induced oxidation of CL in MEC. (a) Typical negative mode ESI-MS spectrum of CL obtained from MEC, LC/MS quantitative assessment of oxidizable (b) and oxidized (c) CL molecular species. CL oxidation products with 1–4 oxygens in each oxidized CL molecular species were detected and shown on inserts. (d) Base peak chromatogram of CL molecular species with m/z 1464. A higher intensity of the peak with m/z 1464 corresponding to oxygenated CL molecular species ((C_{18:2})₃(C_{18:2}-OH), retention

time 12.2 min) was detected in AcD treated MEC. Data are means \pm S.E., n=7, *p<0.03 vs control.

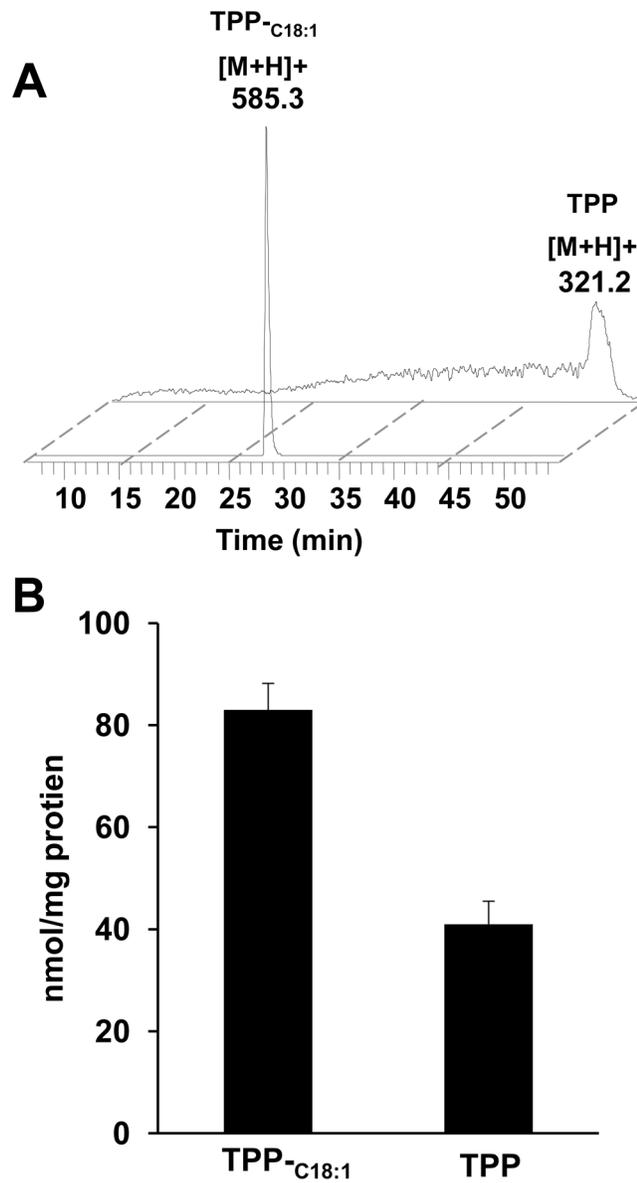

Figure 2. LC/MS analysis of TPP-C_{18:1} and its hydrolysis product, TPP, in mitochondria of MEC

A – LC/MS base peak profiles of TPP-C_{18:1} and TPP in mitochondria from MEC exposed to TPP-C_{18:1}. **B** - Quantitative assessment of TPP-C_{18:1} and TPP in mitochondria. Data are means ± S.E. n=6.

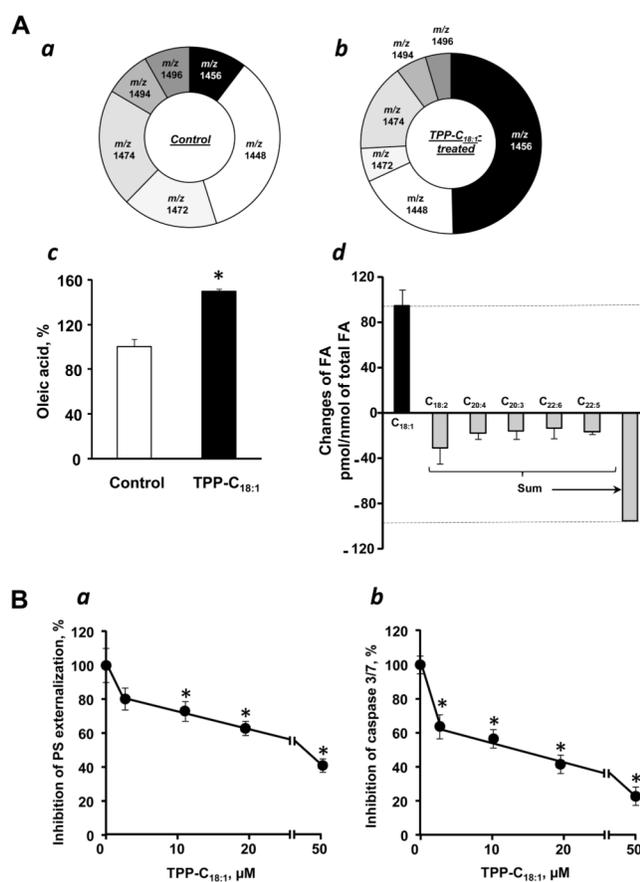

Figure 3. Modification of CL molecular species affects apoptosis induced by AcD in TPP-C_{18:1} treated MEC

A- Effect of TPP-C_{18:1} on the content of CL molecular species in MEC. Content of CL molecular species in control (a) and TPP-C_{18:1} treated cells (b). Content of C_{18:1} (c) and changes in CL fatty acid composition (d) in MEC treated with TPP-C_{18:1}. The amounts of CL molecular species with m/z 1448, m/z 1472, m/z 1494 and m/z 1496 in TPP-C_{18:1} treated cells were dropped to 21.8 ± 3.3 , 7.2 ± 2.0 , 6.5 ± 2.3 and 5.4 ± 1.8 pmol/nmol of total CL from 36.5 ± 3.6 , 17.9 ± 4.3 , 8.7 ± 1.6 and 8.6 ± 1.4 pmol/nmol of total CL in control cells, respectively. Consequently, the amount of CL molecular species with m/z 1456 was increased from 10.8 ± 2.7 to 58.6 ± 7.2 pmol/nmol of total CL. Data are means \pm S.E., $n = 3-10$. **B -** Effect of TPP-C_{18:1} on AcD-induced phosphatidylserine externalization (a) and caspase 3/7 activation (b) in MEC. Data are means \pm S.E., $n=8$, * $p < 0.05$ vs control.

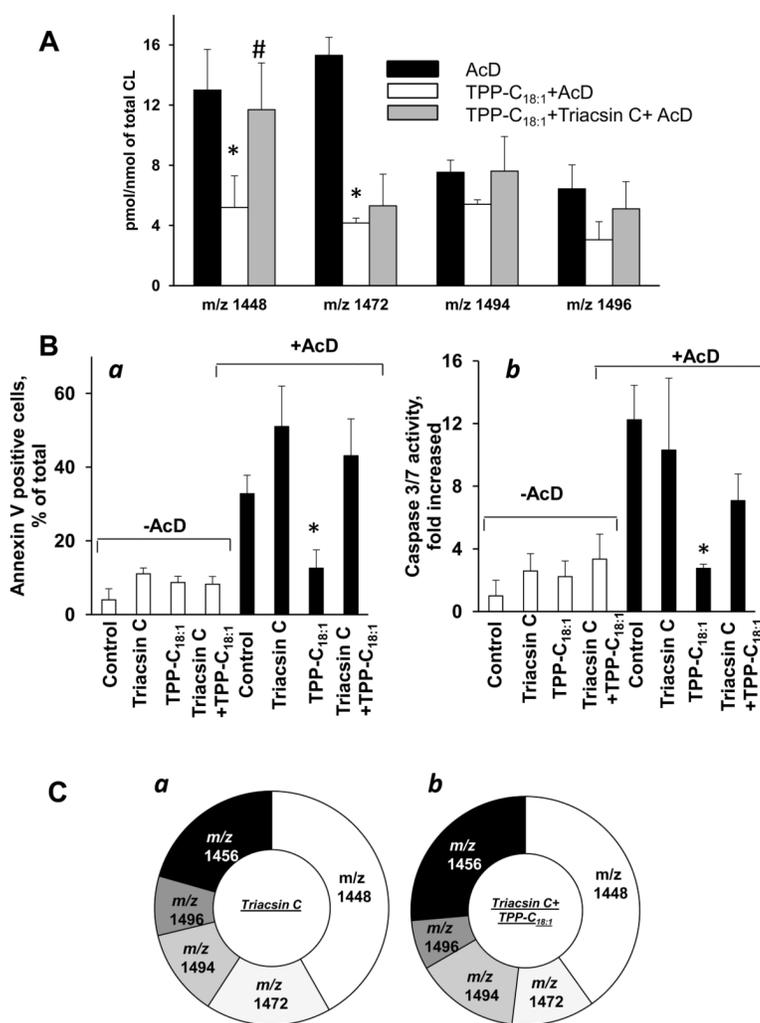

Figure 4. Effect of triacsin C on apoptosis and CL oxidation induced by AcD in MEC treated with TPP-C_{18:1}

A -Effect of AcD, TPP-C_{18:1} and triacsin C on CL oxidation in MEC. Data are presented as increase of oxidized CL molecular species. Data are means \pm S.E., $n=3-7$, * $p<0.05$ vs control. **B** - Effect of TPP-C_{18:1} and triacsin C on AcD-induced phosphatidylserine externalization (a) and caspase 3/7 activation (b) in MEC. Data are means \pm S.E., $n=3-10$, * $p<0.05$ vs control. **C**- Content of CL molecular species in triacsin C treated (a) and triacsin C treated TPP-C_{18:1} exposed cells (b). The amounts of CL molecular species with m/z 1448, m/z 1472, m/z 1494 and m/z 1496 were estimated as 33.3 ± 1.9 , 13.8 ± 2.0 , 9.6 ± 1.8 and 6.5 ± 1.6 pmol/nmol of total CL in triacsin C pre-treated and 37.6 ± 3.9 , 11.0 ± 3.1 , 6.6 ± 4.3 and 3.9 ± 3.1 pmol/nmol of total CL in triacsin pre-treated/TPP-C_{18:1} exposed cells, respectively. Consequently, the amount of CL molecular species with m/z 1456 was 16.4 ± 3.4 to 24.7 ± 4.2 pmol/nmol of total CL. Data are means \pm S.E., $n=3-5$.
