Abstract

Rhodium-catalyzed addition of benzamide C-H bonds to a range of aromatic *N*-sulfonyl aldimines has been developed and proceeds with high functional group compatibility. The synthetic utility of the resulting branched amine products has also been demonstrated by the preparation of isoindoline and isoindolinone frameworks.

Transition-metal catalyzed methods for the direct functionalization of C–H bonds have emerged as powerful alternatives to more traditional reactions that rely heavily on stoichiometric substrate pre-activation. While significant progress has been documented for the addition of sp² C–H bonds across alkenes and alkynes,¹ the identification of analogous methods for the arylation of C–N multiple bonds, such as imines,² isocyanates,³ nitriles,⁴ and isocyanides,⁵ have seen considerably less development. The ability to selectively install nitrogen-based functional groups into molecules through the direct addition of C–H bonds to C–N π -bonds represents a powerful method for rapid and convergent amine synthesis.

Recently, the synthesis of α -branched amines by the Rh(III)-catalyzed addition of 2arylpyridine C–H bonds to *N*-Boc and *N*-sulfonyl imines has been reported.^{2a,b} While these studies serve as excellent proof-of-principle models for C–H additions to C–N multiple bonds, the pyridyl directing group is of limited utility for the synthesis of biologically interesting drugs and natural products. With this limitation in mind, we have focused our efforts on expanding the repertoire of directing groups that are effective for the Rh(III)catalyzed addition of C–H bonds to imines. In particular, we have become interested in the use of benzamide derivatives as directing groups⁶ - an important motif that provides rapid access to organic frameworks that are well-represented in natural products and drugs. Herein, we report the preparation of α -branched amines using the Rh(III)-catalyzed, amidedirected arylation of aromatic *N*-sulfonyl imines. In addition, we have demonstrated the utility of these amine products for the preparation of isoindoline and isoindolinone frameworks.⁷

Our initial investigations focused on the identification of a suitable catalyst and reaction conditions for the regioselective coupling of N,N-dimethyl benzamide (1a) with N-tosyl imine 2a to afford the branched amine product 3a (Table 1). Although the use of 2.5 mol % of [Cp*RhCl₂]₂ proved unsuccessful in catalyzing the reaction (entry 1), employing a mixture of [Cp*RhCl2]2 (2.5 mol %) and AgSbF6 (5 mol %) in CH2Cl2 at 75 °C provided the desired adduct 3a in a 30% yield (entry 2). In comparison, the use of the pre-formed cationic Rh(III) precursor [Cp*Rh(MeCN)₃](SbF₆)₂ showed negligible catalytic activity (entry 3), which we postulate is due to competitive coordination of the acetonitrile ligands with the *N*-tosyl imine to the Cp*Rh catalyst.⁸ Although the use of alternative solvents, such as THF and t-BuOH, provided inferior yields, employing DCE as the reaction solvent led to reactivity similar to that obsevred with CH₂Cl₂ and so DCE was used for all subsequent optimization studies due to its higher boiling point (entries 4 to 6). Further optimization studies showed that improved yields of **3a** could be achieved under higher concentration conditions and that the stoichiometry of reactants had no effect on the reaction outcome (entries 7 and 8). In search of further yield improvements, a series of alternative halide abstracting reagents were screened in combination with [Cp*RhCl2]2 for the preparation of 3a (entries 9 to 12). From this survey it was observed that the use of the more noncoordinating tetrakis(pentafluorophenyl)borate⁹ anion, in place of SbF₆, provided a modest increase in **3a** with a 67% ¹H NMR yield (entry 12).

The influence of the electronic and steric properties of the amide directing group on the progress of the C–H arylation of imine **2a** was next assessed (Table 2). Replacement of the *N*,*N*-dimethyl substituents in **1a** with more bulky diethyl (**1b**) or dibenzyl (**1c**) groups resulted in a marked decrease in yield (entries 2 and 3, 40% and <5%, respectively). In addition, the use of a secondary amide directing group (**1d**), in place of the tertiary amide, provided only trace amine product (entry 4).

Given the observed sensitivity of product formation to the steric profile of the directing group, a series of cyclic tertiary amides were surveyed (entries 5 to 8). The use of both morpholino (**1e**) and piperidinyl (**1f**) amides provided inferior yields of amine product (19% and 34%, respectively) relative to the *N*,*N*-dimethyl amide **1a**. In contrast to these results, the pyrrolidine amide afforded significant gains in product yield, providing the α -branched amine product in an 80% isolated yield (entry 7). In a study by Tanaka and co-workers,^{6g} a similar result was observed for the amide-directed, Rh(I)-catalyzed alkenylation of aromatic and α , β -unsaturated C–H bonds, where substitution of an *N*,*N*-dimethyl amide for a pyrrolidine amide provided dramatic reaction rate enhancement. In entry 8, substitution of the pyrrolidine amide with *rac*-2-methyl pyrrolidine (**1h**) afforded the desired product with activity similar to that observed with amide **1g**; however, negligible diastereoselectivity was achieved for this transformation.

Having defined a highly effective catalyst system and reaction conditions for the addition of pyrrolidine benzamide **1g** to *N*-tosyl imine **2a**, we sought to further explore the reaction scope for pyrrolidine benzamides and a broad range of aromatic *N*-sulfonyl imines (Scheme 1). In addition to the use of *N*-tosyl imines, the more electronegative *N*-nosyl¹⁰ protecting group also served as an effective imine substituent under the standard reaction conditions providing **3i** in a 85% isolated yield. While the use of electron-deficient aromatic imines possessing nitro (**3j**), carbomethoxy (**3k**), trifluoromethyl (**3l**), and chloro (**3n**) para substituents delivered branched amine products in good to excellent yields, imines with electron-donating substitutents provided only moderate yields (**3o**-**3p**). In addition, aromatic imines with *meta*- and *ortho*-fluoro groups were effective coupling partners under optimized conditons (**3q**-**3r**). The 2-thienyl-subtituted branched amine product **3s** was isolated in a 58% yield from the corresponding heteroaromatic imine substrate.

Electron-rich or -poor pyrrolidine amides featuring *meta*- or *para*-substitution gave the desired branched amine products with good to excellent yields (3t-3x, 49-85%). Moreover, when empoying *meta*-substituted amide substrates exclusive reaction at the less-hindered C-H site occurred (3w-3x).

The aggregate collection of benzamide and imine substrates investigated also established a high level of functional group compatibility. Only the nitrile group (**3m**) resulted in poor yields, presumably due to competitive coordination to the metal. Otherwise, nitro (**3i**), ester (**3k**), keto (**3v**), chloro (**3n**), fluoro (**3q**), bromo (**3w**), thienyl (**3s**) methoxy (**3t**), and trifluoromethyl (**3u**) functional groups were all compatible with the reaction conditions.

The product regiochemistry observed for the Rh(III)-catalyzed addition of benzamide substrates to imines is most consistent with a Rh-mediated C–H cleavage step directed by the Lewis basic amide group rather than a more traditional electrophilic aromatic substitution (EAS) mechanism. Specifically, exclusive *ortho*-functionalization is observed in all cases, as opposed to the expected *meta*-substitution for EAS of a deactivated amide substrate.

To demonstrate the synthetic versatility of the C–H addition products, several transformations of **3g** were performed (Scheme 2). Using a previously developed protocol for the reduction of tertiary amides to the corresponding aldehydes,¹¹ treatment of **3g** with Cp₂Zr(H)Cl (Schwartz's reagent) promoted reduction of the pyrrolidine amide to a cyclic aminal intermediate,¹² which could be further reduced with NaBH₄ in trifluoroacetic acid to the isoindoline **4** in reasonable overall yield over the two steps. The isoindolinone **5** was also obtained in excellent yield by the *p*-TsOH mediated transamidation/cyclization of **3g**. Cleavage of the *N*-Ts protecting group in **5** was readily achieved by exposure to Na/ naphthalene. Furthermore, reduction of *in situ* prepared **5** with LiAlH₄ provided access to the corresponding alcohol **7** in a 83% yield, which is poised for further synthetic elaboration.

In summary, mixtures of $[Cp*RhCl_2]_2$ and $AgB(C_6F_5)_4$ have been shown to catalyze the addition of *N*,*N*-dialkyl benzamide C–H bonds to a variety of aromatic *N*-sulfonyl imines to provide branched amine products. The obtained products were also shown to be easily transformed into isoindoline and isoindolinone frameworks. Further investigations to extend the reaction scope and illustrate applications of this process in organic synthesis are underway.
