SUMMARY

The *let-7* tumor suppressor microRNAs are known for their regulation of oncogenes, while the RNA-binding proteins *Lin28a/b* promote malignancy by blocking *let-7* biogenesis. In studies of the *Lin28/let-7* pathway, we discovered unexpected roles in regulating metabolism. When overexpressed in mice, both *Lin28a* and *LIN28B* promoted an insulin-sensitized state that resisted high fat diet-induced diabetes, whereas muscle-specific loss of *Lin28a* and overexpression of *let-7* resulted in insulin resistance and impaired glucose tolerance. These phenomena occurred in part through *let-7*-mediated repression of multiple components of the insulin-PI3K-mTOR pathway, including *IGF1R*, *INSR*, and *IRS2*. The mTOR inhibitor rapamycin abrogated the enhanced glucose uptake and insulin-sensitivity conferred by *Lin28a* *in vitro* and *in vivo*. In addition, we found that *let-7* targets were enriched for genes that contain SNPs associated with type 2 diabetes and fasting glucose in human genome-wide association studies. These data establish the *Lin28/let-7* pathway as a central regulator of mammalian glucose metabolism.

INTRODUCTION

There is an emerging consensus that metabolic disease and malignancy share common biological mechanisms. Reprogramming towards glycolytic metabolism can increase a cancer cell's ability to generate biomass, a phenomenon termed the "Warburg Effect" (Denko, 2008; Engelman et al., 2006; Gao et al., 2009; Guertin and Sabatini, 2007; Laplante and Sabatini, 2009; Vander Heiden et al., 2009; Yun et al., 2009). Likewise, many genes identified in type 2 diabetes (T2D) genome wide association studies (GWAS) are proto-oncogenes or cell cycle regulators (Voight et al., 2010). MicroRNAs (miRNAs) are also emerging as agents of metabolic and malignant regulation in development and disease (Hyun et al., 2009; Peter, 2009). The *let-7* miRNA family members act as tumor suppressors by negatively regulating the translation of oncogenes and cell cycle regulators (Johnson et al., 2005; Lee et al., 2007; Mayr et al., 2007; Kumar et al., 2008). Widespread expression and redundancy among the well-conserved *let-7* miRNAs raise the question of how cancer and embryonic cells are able to suppress this miRNA family to accommodate rapid cell proliferation. In human cancers, loss of heterozygosity, DNA methylation, and transcriptional suppression have been documented as mechanisms to reduce *let-7* (Johnson et al., 2005; Lu et al., 2007). Another mechanism for *let-7* downregulation involves the RNA-binding proteins *Lin28a* and *Lin28b* (collectively referred to as *Lin28a/b*), which are highly expressed during normal embryogenesis and upregulated in some cancers to potently and selectively block the maturation of *let-7* (Heo et al., 2008; Newman et al., 2008; Piskounova et al., 2008; Rybak et al., 2008; Viswanathan et al., 2008). By repressing the biogenesis of *let-7* miRNAs and in some cases through direct mRNA binding and enhanced translation (Polesskaya et al., 2007; Xu and Huang, 2009; Xu et al., 2009; Peng et al., 2011), *Lin28a/b* regulate an array of targets involved in cell proliferation and differentiation in the context of embryonic cells, stem cells, and cancer.

Little is known about the *in vivo* function of the *Lin28/let-7* axis. The pathway was first revealed in a screen for heterochronic mutants in *C. elegans*, where loss of *lin-28* resulted in precocious vulval differentiation and premature developmental progression (Ambros and Horvitz, 1984; Moss et al., 1997; Nimmo and Slack, 2009), whereas loss of *let-7* led to reiteration of larval stages and delayed differentiation (Abbott et al., 2005; Reinhart et al., 2000). We previously showed that *Lin28a* gain of function promotes mouse growth and delays sexual maturation, recapitulating the heterochronic effects of *lin-28* and *let-7* in *C. elegans*, as well as the height and puberty phenotypes linked to human genetic variation at the *Lin28b* locus identified in GWAS (Zhu et al., 2010). The conservation of *Lin28* and *let-7*'s biochemical and physiological functions throughout evolution suggests an ancient mechanism for *Lin28* and *let-7*'s effects on growth and developmental timing.

In this report we found that both *Lin28a* and *LIN28B* transgenic mice were resistant to obesity and exhibited enhanced glucose tolerance. In contrast, muscle-specific *Lin28a* knockout and inducible *let-7* transgenic mice displayed glucose intolerance, suggesting that the *Lin28/let-7* pathway plays a specific and tightly regulated role in modulating glucose metabolism in mammals. *In vitro* experiments revealed that *Lin28a* enhances glucose uptake via an increase in insulin-PI3K-mTOR signaling due in part to the derepression of multiple direct *let-7* targets in the pathway, including *IGF1R*, *INSR*, *IRS2*, *PIK3IP1*, *AKT2*, *TSC1* and *RICTOR*. Experiments with the mTOR-specific inhibitor rapamycin demonstrate that *Lin28a* regulates growth, glucose tolerance, and insulin sensitivity in an mTOR-dependent manner *in vivo*. In addition, analysis of T2D and fasting glucose whole genome associations suggests a genetic connection between multiple genes regulated by *let-7* and glucose metabolism in humans. These metabolic functions for *Lin28a/b* and *let-7 in vivo* provide a mechanistic explanation for how this pathway might influence embryonic growth, metabolic disease and cancer.

RESULTS

Lin28a Tg mice are resistant to obesity and diabetes

We previously described a tetracycline-inducible *Lin28a* transgenic mouse that showed leaky constitutive *Lin28a* expression in the absence of induction (See Experimental Procedures, “*Lin28a* Tg” mice: Zhu et al., 2010). In that study, we showed that these mice cleared glucose more efficiently during glucose and insulin tolerance testing (GTT and ITT), classic metabolic tests used for the characterization of whole animal glucose handling. Given that young *Lin28a* Tg mice exhibited enhanced glucose metabolism, we tested if old *Lin28a* Tg mice were also resistant to age-induced obesity. Compared to *Lin28a* Tg mice, wild-type mice fed a normal diet gained significantly more fat mass with age (Figure 1A). Dual Energy X-ray Absorptiometry scans showed increased percentage lean mass and reduced percentage body fat in the *Lin28a* Tg mice (Figure 1B,C). To rule out behavioral alterations, we measured activity over three days in isolation cages and found no differences in horizontal activity, O₂/CO₂ exchange, and food/water intake between wild-type and Tg mice (Figure S1A,B). To determine if these mice were resistant to HFD-induced obesity, we fed mice a diet containing 45% kcals from fat, and observed resistance to obesity in the *Lin28a* Tg mice (Figure 1D). *Lin28a* Tg mice consumed as much high-fat food as their wild-type littermates, ruling out anorexia (data not shown). Furthermore, we inquired if *Lin28a* Tg mice were resistant to HFD-induced diabetes and found that they had markedly improved glucose tolerance and insulin sensitivity under HFD conditions (Figure 1E,F). *Lin28a* Tg mice also showed resistance to HFD-induced hepatosteatosis (Figure 1G). Taken together, leaky *Lin28a* expression in the muscle, skin and connective tissues (Zhu et al., 2010) protected against obesity and diabetes in the context of aging and HFD.

iLIN28B Tg mice are likewise resistant to diabetes

Although *Lin28a* and *Lin28b* both block *let-7* miRNAs, they are differentially regulated, resulting in distinct expression patterns during normal development and malignant transformation (Guo et al., 2006; Viswanathan et al., 2009). Given that *LIN28B* is overexpressed more frequently than *LIN28A* in human cancer, we sought to determine if *LIN28B* exerts a similar effect on glucose metabolism. Thus, we generated a mouse strain with human *LIN28B* driven by a tetracycline transactivator *rtTA* placed under the control of the *Rosa26* locus (*iLIN28B* mouse) (See Experimental Procedures). After 14 days of treatment with the tetracycline analogue doxycycline (dox), high levels of *LIN28B* were induced and mature *let-7*'s were repressed in metabolically important organs (Figure 1H,I), resulting in hypoglycemia with an average fasting glucose of <50 mg/dL in induced mice compared to >150 mg/dL in control mice ($p < 0.01$). To determine the kinetics of this effect,

we measured fed state glucose daily and noted falling glucose levels after 5 days (Figure 1J). Glucose and insulin tolerance tests on dox-induced animals on normal diets showed considerable improvements in glucose tolerance and insulin sensitivity (Figure 1K,L). In checking for islet β cell hyperactivity, we found that *iLIN28B* mice produced no more insulin than control littermates during glucose challenge (data not shown). Under HFD, we found that induced *iLIN28B* mice were surprisingly resistant to weight gain (Figure 1M) despite a trend towards increased food intake (9.9 vs. 4.8 g/mouse/day; $p = 0.075$). These mice continued to exhibit superior glucose tolerance after 14 days of dox induction under HFD (Figure 1N), when average weights were 34.5 ± 1.05 grams for controls and 27.1 ± 0.99 grams for *iLIN28B* mice, demonstrating that HFD had a strong obesogenic and diabetogenic effect on control but not on *LIN28B* induced animals. Unlike the *Lin28a* Tg mice, expression was not leaky in the *iLIN28B* mice (Figure 1H and 3F) and uninduced mice exhibited no growth or glucose phenotypes (Figure S1C,D), making this a better model for inducible *Lin28* hyperactivation. These data show that both *Lin28* homologues have similar effects on glucose metabolism and obesity, suggesting that these effects are mediated through common mRNA or miRNA targets of the *Lin28* family.

Lin28a is physiologically required for normal glucose homeostasis

We then asked if *Lin28a* is physiologically required for normal glucose metabolism in one specific adult tissue compartment, skeletal muscle, since previous studies have found low but significant levels of *Lin28a* expression in the muscle tissues of mice (Yang and Moss, 2003; Zhu et al, 2010). We generated a skeletal muscle-specific knockout of *Lin28a* by crossing the mouse *myogenic factor 5 Cre* recombinase strain (*Myf5-Cre*) to the *Lin28a^{fl/fl}* conditional loss of function mouse (See Experimental Procedures). These muscle-specific knockout mice showed impaired glucose tolerance (Figure 1O) and insulin resistance (Figure 1P) relative to wild-type littermates, demonstrating that *Lin28a* activity in skeletal muscles is required for normal glucose homeostasis. We analyzed miRNA expression in muscle tissue by qRT-PCR and found no significant difference in *let-7* levels during adult (data not shown) or embryonic stages (Figure S1E), suggesting that *Lin28a* loss of function affects glucose homeostasis either through *let-7*-independent mRNA binding or through changes in the spatiotemporal distribution of *let-7* miRNA. Together, these data show that *Lin28* isoforms are important and essential regulators of glucose homeostasis.

iLet-7 mice are glucose intolerant

In addition to their ability to suppress *let-7* biogenesis, *Lin28a* and *Lin28b* also regulate mRNA targets such as *Igf2*, *HMGAI*, *OCT4*, histones and cyclins through non-*let-7* dependent mechanisms of mRNA binding and enhanced translation (Polesskaya et al., 2007; Xu and Huang, 2009; Xu et al., 2009; Peng et al., 2011). To test if altered *let-7* expression might produce the opposite phenotypes of *Lin28a/b* gain of function, we generated a mouse strain in which *let-7g* can be induced with dox under the control of the *Rosa26* locus (*iLet-7* mouse, See Experimental Procedures). To ensure that endogenous *Lin28* would not block *pri-* or *pre-let-7g* biogenesis, we used a chimeric *let-7g* species called *let-7S21L* (*let-7g* Stem, *mir-21* Loop), in which the loop region of the precursor miRNA derives from *mir-21* and cannot be bound by *Lin28*, thus allowing for *let-7* processing despite *Lin28* expression (Piskounova et al., 2008). Global transgene induction from three weeks of age onwards increases mature *let-7g* levels in liver (>50-fold), skin (>20-fold), fat (~4-fold) and muscle (~4-fold) (Figure 2A). This level of *let-7* overexpression led to reduced body size and growth rates in induced animals (Figure 2B,C). Growth retardation was proportional and not manifested as preferential size reduction in any particular organs (Figure S2A). Similar to the *iLIN28B* mice, leaky expression was not detected and uninduced male mice exhibited no growth or glucose phenotypes (Figure S2B–D).

After 5 days of *let-7* induction, these *iLet-7* mice produced an increase in fed state glucose (Figure 2D). GTT revealed glucose intolerance in mice fed normal (Figure 2E) or HFD (Figure 2F). Surprisingly, ITT failed to detect a difference in insulin sensitivity (Figure 2G). The decreased glucose tolerance in the setting of comparable insulin sensitivity suggested either decreased insulin production from islet β cells in response to glucose, or higher insulin secretion to compensate for peripheral insulin resistance. Thus, we measured insulin production following glucose challenge, and found that *iLet-7* mice produced more insulin than controls (Figure 2H). These results demonstrated that broad overexpression of *let-7* results in peripheral glucose intolerance and compensatory overproduction of insulin from islet β cells.

To test if *let-7* induction could abrogate the glucose uptake phenotype of *LIN28B* overexpression, we crossed the *iLIN28B* to the *iLet-7* inducible mice. After 10 days of induction, simultaneous induction of *LIN28B* and *let-7g* did not result in any differences in glucose tolerance (Figure 2I,J), in contrast to *LIN28B* or *let-7g* induction alone. Taken together, the opposing effects of *Lin28* and *let-7* expression on glucose regulation show that *Lin28* overexpression influences metabolism in part by suppressing *let-7*, and that *let-7* alone is sufficient to regulate glucose metabolism *in vivo*.

Insulin-PI3K-mTOR signaling is activated by *Lin28a/b* and suppressed by *let-7*

To dissect the molecular mechanism of the effects of *Lin28* and *let-7* on glucose regulation, we turned to the C2C12 cell culture system. Overexpression of *Lin28a* in C2C12 myoblasts resulted in protein levels of *Lin28a* similar to that observed in mouse embryonic stem cells (ESCs) (Figure 3A), and led to robust *let-7* suppression (Figure 3B). In C2C12 myotubes differentiated for 3 days, *Lin28a* promoted Ser473 phosphorylation of Akt and Ser235/236 phosphorylation of S6 ribosomal protein, suggesting activation of the PI3K-mTOR pathway (Figure S3A). In this setting, *Lin28a* increased myotube glucose uptake by 50% (Figure 3C). *Lin28a*-dependent glucose uptake was abrogated by 24hr treatment with the PI3K/mTOR inhibitor LY294002 or the mTOR inhibitor rapamycin (Figure 3C), but not the MAPK/ERK inhibitor PD98059 (Figure S3B), demonstrating that *Lin28a*-dependent glucose uptake requires the PI3K-mTOR pathway.

To exclude myotube differentiation-dependent phenomena, we tested the effects of *Lin28a* on PI3K-mTOR signaling in undifferentiated myoblasts under serum-fed, serum-starved, and insulin-stimulated conditions (Figure 3D). In the serum-fed state, we found that *Lin28a* promoted the activation of PI3K/Akt signaling by increasing Akt phosphorylation at both Ser473 and Thr308, compared to the pBabe control. Furthermore, we found that *Lin28a* robustly increased the phosphorylation of mTORC1 signaling targets S6 and 4EBP1 in the serum-fed state. Serum-starvation for 18 hours abrogated the phosphorylation of Akt, S6 and 4EBP1, indicating that *Lin28a*-induction of PI3K-mTOR signaling requires exogenous growth factor stimulation. Upon insulin stimulation, Akt phosphorylation increased dramatically and, both phospho-S6 and phospho-4EBP1 levels were increased even further by *Lin28a* overexpression, suggesting that *Lin28a* increases the insulin-sensitivity of C2C12 myoblasts. Importantly, we found that rapamycin abrogated the *Lin28a*-induction of phospho-S6 and phospho-4EBP1 upon insulin stimulation, but did not affect *let-7* levels (Figure S3C) or *Lin28a* itself (Figure 3D), indicating that the mTOR dependence is occurring downstream of *Lin28a*.

To test if the effects of *Lin28a* on insulin-PI3K-mTOR signaling are *let-7*-dependent, we transfected either mature *let-7f* duplex or a negative control miRNA into both *Lin28a*-overexpressing and pBabe control myoblasts (Figure S3D and Figure 3E). Because mature *let-7* duplexes cannot be bound and inhibited by *Lin28a* protein, this experiment tests if PI3K-mTOR activation is occurring downstream of *let-7*. Transfection with control miRNA

did not affect *Lin28a*-induction of the phosphorylation of Akt, S6, or 4EBP1 in serum-starved myoblasts upon insulin stimulation. Transfection with *let-7f*, however, attenuated the *Lin28a*-induction of phospho-Akt (Ser473), and abrogated the increase in S6 and 4EBP1 phosphorylation upon insulin stimulation in *Lin28a*-overexpressing myoblasts (Figure 3E). In pBabe control myoblasts, *let-7* duplex still suppressed S6 and 4EBP1 phosphorylation in the serum-fed state, serum-starved, and insulin-stimulated conditions, relative to total S6 and 4EBP1 protein. The suppression of mTOR signaling by *let-7* even in the absence of *Lin28a* implies that *let-7* can act independently downstream of *Lin28a*. Together with data indicating that *let-7* abrogates *Lin28a*-specific induction of p-Akt, p-S6 and p-4EBP1 upon insulin stimulation, this demonstrates that the effects of *Lin28a* on PI3K-mTOR signaling are at least in part due to *let-7* and that *Lin28* and *let-7* exert opposing effects on PI3K-mTOR signaling.

To test if these effects of *Lin28* on insulin-PI3K-mTOR signaling are also relevant *in vivo*, we examined the quadriceps muscles of *iLIN28B* mice and found that dox-induction led to increases in the phosphorylation of Akt (S473), S6 and 4EBP1, the targets of PI3K-mTOR signaling (Figure 3F). Furthermore, the Insulin-like growth factor 1 receptor (Igf1r) and the Insulin receptor (Insr) proteins were also upregulated in the muscles upon *LIN28B* induction, reinforcing the fact that *Lin28a/b* drives insulin-PI3K-mTOR signaling in C2C12 myoblasts and within mouse tissues. On the other hand, similar analysis of the *Lin28a* muscle-specific knockout mice revealed reduced Insr and p-4EBP1 expression (Figure 3G), demonstrating that *Lin28a* is both necessary and sufficient to influence glucose metabolism through the regulation of insulin-PI3K-mTOR signaling *in vivo*.

Lin28a/b and let-7 regulate genes in the insulin-PI3K-mTOR pathway

On the RNA level, *Lin28a* overexpression in C2C12 myoblasts leads to an increase in mRNA levels of multiple genes in the insulin-PI3K-mTOR signaling pathway (Figure S4A). Although both *Lin28a* suppression of *let-7* and direct *Lin28a* binding to mRNAs could increase mRNA stability and thus increase mRNA levels, it is possible that these increases do not reflect direct interactions. To find direct targets, we performed a bioinformatic screen using the TargetScan 5.1 algorithm (Grimson et al., 2007), and found that 16 genes in the insulin-PI3K-mTOR pathway contained evolutionarily conserved *let-7* binding sites in their respective 3' UTRs (Figure 4A,B). Next, we performed 3' UTR luciferase reporter assays to determine if these genes were *bona fide* and direct targets of *let-7*. To do this, we generated luciferase reporters with twelve human 3' UTR fragments containing conserved *let-7* sites. Luciferase reporter expression in human HEK293T cells after transfection of either mature *let-7f* duplex or a negative control miRNA demonstrated that the 3' UTRs of *INSR*, *IGF1R*, *IRS2*, *PIK3IP1*, *AKT2*, *TSC1* and *RICTOR* were targeted by *let-7* for suppression (Figure 4C). Three-base mismatch mutations in the seed region of the *let-7* binding sites abrogated *let-7*'s suppression of *INSR*, *IGF1R* and *IRS2*. To confirm that the luciferase reporters predicted actual changes in protein expression mediated by *let-7*, we assayed the endogenous expression of some of these proteins upon *Lin28a/b* overexpression. We found that an increase in *Lin28a* upregulated *Irs2* (Figure 4D) *in vitro*, and that an increase in *LIN28B* upregulated *Igf1r* and *Insr* protein in skeletal muscles *in vivo* (Figure 3F). Conversely, *INSR* and *IRS2* are reduced upon both *let-7f* transfection and *LIN28B* shRNA knockdown in HEK293T, demonstrating that these regulatory mechanisms hold in both mouse and human cells, and in the setting of both *LIN28B* gain and loss of function (Figure 4E). This establishes a direct mechanism for *let-7*'s repression and *Lin28*'s derepression of multiple components in the insulin-PI3K-mTOR signaling cascade.

Previously, *Lin28a* has been shown to enhance *Igf2* translation independently of *let-7* (Polesskaya et al., 2007), offering an alternative mechanism by which *Lin28a* might activate the insulin-PI3K-mTOR pathway. To determine the relative contribution of this mechanism,

we performed *in vitro* and *in vivo* loss of function experiments. Following siRNA knockdown of *Igf2* in C2C12 (the efficacy of knockdown is shown in Figure S4B), we found only minimal changes in S6 and 4EBP1 phosphorylation (Figure S4C). In these C2C12 myotubes, glucose uptake was unaffected by *Igf2* knockdown, but significantly decreased by *let-7a* (Figure S4D). In addition, we crossed the *Lin28a* Tg mice with *Igf2* knockout mice and found that the absence of *Igf2* did not abrogate enhanced glucose uptake, insulin sensitivity, or the anti-obesity effect mediated by *Lin28a* (Figure S4E–H). Taken together, these data indicate that the metabolic phenotypes we have observed are not solely due to the ability of *Lin28a/b* to promote translation of *Igf2* mRNA, but do not rule out the possibility that *Lin28a/b* might modulate other mRNAs in the insulin-PI3K-mTOR signaling pathway.

mTOR mediates *Lin28a*'s enhancement of growth and glucose metabolism *in vivo*

Given that *Lin28a* activates the insulin-PI3K-mTOR pathway both *in vitro* and *in vivo*, we asked whether the metabolic effects of *Lin28a in vivo* could be abrogated by pharmacological inhibition of the mTOR pathway. To do this, we injected *Lin28a* Tg and wild-type littermates with rapamycin 3 times per week beginning when mice were 18 days old. Rapamycin abrogated the growth enhancement in *Lin28a* Tg mice at doses that had minimal growth suppressive effects on wild-type mice (Figure 5A,B), suggesting that *Lin28a* promotes growth in an mTOR-dependent manner. Selective suppression of *Lin28a*-driven growth was observed using several parameters: weight (Figure 5B,C), crown-rump length (Figure 5D), and tail width (Figure 5E). We also tested if the enhanced glucose uptake phenotype *in vivo* was likewise dependent on mTOR. Indeed, glucose tolerance testing showed that short-term rapamycin reversed the enhanced glucose uptake effect of *Lin28a* (Figure 5F,G) and reduced the insulin-sensitivity of *Lin28a* Tg mice to wild-type levels (Figure 5H,I). These data indicate that the glucose uptake, insulin sensitivity and animal growth phenotypes of *Lin28a* overexpression *in vivo* are dependent on mTOR signaling.

let-7 target genes are associated with type 2 diabetes in human GWAS

Finally, we sought to assess the relevance of the *Lin28/let-7* pathway to human disease and metabolism, using human genetic studies of T2D and fasting glucose levels. Because the *Lin28/let-7* pathway has not been previously implicated in T2D, we first asked whether any of the genes that lie in T2D association regions identified in T2D GWAS and meta-analyses (Voight et al., 2010) are known or predicted *let-7* targets. We used TargetScan 5.1 to computationally predict *let-7* targets (Grimson et al., 2007), and found that 14 predicted *let-7* target genes lie in linkage disequilibrium to 39 validated common variant associations with T2D, including *IGF2BP2*, *HMGA2*, *KCNJ11* and *DUSP9* (strength of T2D association signals $p < 4 \times 10^{-9}$) (Table 1). Of the computationally predicted *let-7* targets associated with T2D, *IGF2BP1/2/3* and *Hmga2* have been verified as *let-7* targets in several studies (Boyerinas et al., 2008; Mayr et al., 2007). To validate the connection between *Lin28* and GWAS candidate genes, we analyzed the expression of *Igf2bp* and *Hmga* family members in C2C12 cells with and without *Lin28a* overexpression, and observed increases in *Igf2bp1*, *Igf2bp2*, and *Hmga2* mRNA following *Lin28a* overexpression (Figure 6A). To ensure that this was not a C2C12- or muscle-specific phenomenon, we confirmed the upregulation of these genes in 3T3 cells following human *LIN28A* or *LIN28B* overexpression on the mRNA (Figure 6B) and the protein level for the *Igf2bp* family (Figure 6C). We also observed increased expression of *Igf2bp2* and *Igf2bp3* (Figure 6D) in *Lin28a* Tg muscle, confirming this link *in vivo*.

We next asked whether there is a more widespread connection between T2D susceptibility and *let-7* targets, in addition to the targets in validated T2D association regions ($p < 5 \times 10^{-8}$).

To address this, we applied a computational method called MAGENTA (Meta-Analysis Gene-set Enrichment of variaNT Associations) (Segre et al., 2010) to GWAS meta-analyses of T2D and fasting glucose blood levels, and tested whether the distributions of disease or trait associations in predefined *let-7* target gene sets are skewed towards highly ranked associations (including ones not yet reaching a level of genome-wide significance) compared to matched gene sets randomly sampled from the genome (Table 1). We tested three types of *let-7* target definitions with increasing levels of target validation, from *in silico* predicted *let-7* targets using TargetScan 5.1 (Grimson et al., 2007) to experimentally defined targets. For the latter, we used (i) a set of genes with at least one *let-7* site in their 3' UTR and whose mRNA was downregulated by *let-7b* overexpression in primary human fibroblasts (Legesse-Miller et al., 2009), and (ii) a set of genes whose protein levels were most strongly downregulated by *let-7b* overexpression in HeLa cells (Selbach et al., 2008). We first tested the *let-7* target sets against the latest T2D meta-analysis of eight GWAS (called DIAGRAM+) (Voight et al., 2010), and found significant enrichment (Table 1). The enrichment rose from 1.05-fold for the broadest definition of *let-7* targets predicted using TargetScan (~1800 genes; $p = 0.036$) to 1.92-fold for the experimentally validated target set based on protein level changes in response to *let-7* overexpression (~100 genes; $p = 1 \times 10^{-6}$). In the latter case, an excess of about 20 genes regulated by *let-7* at the protein level are predicted to contain novel SNP associations with T2D. Notably *IGF2BP2*, which is a canonical *let-7* target that lies in a validated T2D association locus, was found in all types of *let-7* target definitions in Table 1. Furthermore, the genes driving the T2D enrichment signals for the different *let-7* target sets include both functionally redundant homologues of T2D-associated genes, such as *IGF2BP1* (*IGF2BP2*), *HMGA1* (*HMGA2*), *DUSP12* and *DUSP16* (*DUSP9*), and genes in the insulin-PI3K-mTOR pathway, including *IRS2*, *INSR*, *AKT2* and *TSC1* (best local SNP association $p = 10^{-4}$ to 4×10^{-3}).

We next tested for enrichment of *let-7* target gene associations with fasting glucose levels, using data from the MAGIC (Meta-Analysis of Glucose and Insulin-related traits Consortium) study of fasting glucose levels (Dupuis et al., 2010). We observed an over-representation of multiple genes modestly associated with fasting glucose at different levels of significance for the different *let-7* target gene sets (Table 1). The strongest enrichment was found in the genes downregulated at the mRNA level by *let-7*, an enrichment of 1.20 fold over expectation ($p = 1 \times 10^{-4}$). Taken together, our human genetic results support the hypothesis that genes regulated by *let-7* influence human metabolic disease and glucose metabolism.

Recently it has also become clear that Lin28a/b has important *let-7*-independent roles in RNA metabolism, as evidenced by numerous direct mRNA targets whose translation is enhanced by LIN28A (Peng et al., 2011). Using GSEA, we found that this list of direct mRNA targets is also significantly enriched for glucose, insulin and diabetes-related genes (Table S1). Thus, Lin28a/b may regulate metabolism through direct mRNA-binding as well as *let-7* targets.

DISCUSSION

Lin28 and *let-7* are mutually antagonistic regulators of growth and metabolism

Our work defines a new mechanism of RNA-mediated metabolic regulation. In mice, *Lin28a* and *LIN28B* overexpression results in insulin sensitivity, enhanced glucose tolerance, and resistance to diabetes. Our analysis of *iLet-7*Tg mice shows that *let-7* upregulation is also sufficient to inhibit normal glucose metabolism, supporting the idea that gain of *Lin28a/b* exerts effects on whole animal glucose metabolism at least in part through *let-7* suppression. Previously, we showed that transgenic overexpression of *Lin28a* causes enhanced growth and delayed puberty, phenotypes that mimicked human traits linked to

genetic variation in the *Lin28/let-7* pathway in GWAS (Zhu et al., 2010). Given that *Lin28a/b* is downregulated in most tissues after embryogenesis, while *let-7* increases in adult tissues, lingering questions from our earlier report were first, whether *let-7* was sufficient to influence organismal growth, and second, what function does *let-7* have in adult physiology? Our observation that the *iLin28a*, *iLIN28B*, and *iLet-7*Tg gain of function mice, as well as muscle-specific *Lin28a* loss of function mice manifest complementary phenotypes supports the notion that *Lin28a/b* and *let-7* are both regulators of growth and developmental maturation. We propose that different developmental time-points demand distinct metabolic needs, and that global regulators such as *Lin28* temporally coordinate growth with metabolism. The dynamic relationship between *Lin28*, *let-7* and metabolic states during major growth milestones in mammals is reminiscent of the heterochronic mutant phenotypes originally defined in *C. elegans* (Ambros and Horvitz, 1984; Moss et al., 1997; Boehm and Slack, 2005), and suggests that metabolism, like differentiation, is temporally controlled.

Lin28a/b and let-7 influence glucose metabolism through the insulin-PI3K-mTOR pathway

We have shown that *Lin28a/b* and *let-7* regulates insulin-PI3K-mTOR signaling, a highly conserved pathway that regulates growth and glucose metabolism throughout evolution. PI3K/Akt signaling is known to promote Glut4 translocation to upregulate glucose uptake, while mTOR signaling can promote glucose uptake and glycolysis by changing gene expression independently of Glut4 translocation (Brugarolas et al., 2003; Buller et al., 2008; Duvel et al., 2010). Previous studies have shown that *Lin28a* directly promotes Igf2 (Poleskaya et al., 2007) and *HMGA1* translation (Peng et al., 2011), and that *let-7* suppresses IGF1R translation in hepatocellular carcinoma cells (Wang et al., 2010). Consistent with these findings, our results define a model whereby *Lin28a/b* and *let-7* coordinately regulate the insulin-PI3K-mTOR pathway at multiple points (Figure 6E), a concept that is consistent with the hypotheses that miRNAs and RNA binding proteins regulate signaling pathways by tuning the production of a broad array of proteins rather than switching single components on or off (Kennell et al., 2008; Hatley et al., 2010; Small and Olson, 2011). Coordinated regulation is important because negative feedback loops exist within the insulin-PI3K-mTOR pathway. Loss-of-function and pharmacological inhibition studies have shown that the mTOR target S6K1, for instance, inhibits and desensitizes insulin-PI3K signaling by phosphorylating IRS1 protein and suppressing *IRS1* gene transcription (Harrington et al., 2004; Shah et al., 2004; Tremblay et al., 2007; Um et al., 2004). Conversely, TSC1-2 promotes insulin-PI3K signaling by suppressing mTOR signaling (Harrington et al., 2004; Shah et al., 2004). Although the effects of *let-7* and *Lin28a/b* on the expression of individual genes are modest, simultaneous regulation of multiple components such as *IGF2*, *IGF1R*, *INSR*, *IRS2*, *PIK3IP1*, *AKT2*, *TSC1*, *RICTOR* in the insulin-PI3K-mTOR signaling pathway could explain how this RNA processing pathway coordinately regulates insulin sensitivity and glucose metabolism by effectively bypassing these negative feedback loops.

Whereas our work has implicated *let-7* as a regulator of insulin-PI3K-mTOR signaling, we do not exclude a parallel role for direct mRNA targets of *Lin28a/b* in glucose metabolism, a hypothesis supported by the recent findings that *HMGA1* is translationally regulated by *LIN28A* and mutated in 5–10% of T2D patients (Peng et al., 2011; Chiefari et al., 2011). Such non-*let-7* functions are also suggested by the fact that muscle-specific loss of *Lin28a* results in glucose derangement without significant *let-7* changes. Nevertheless, it remains likely that during other developmental stages or in other tissues, *let-7* suppression by *Lin28a* or *Lin28b* is required for normal glucose homeostasis. The effects of the *Lin28/let-7* pathway on glucose metabolism in our murine models, together with our observation that

genes regulated by *let-7* are associated with T2D risk in humans, indicates important functional roles for both *Lin28a/b* and *let-7* in human metabolism.

let-7 targets are relevant to disparate human diseases: cancer and T2D

Metabolic reprogramming in malignancy is thought to promote a tumor's ability to produce biomass and tolerate stress in the face of uncertain nutrient supplies (Vander Heiden et al., 2009). During their rapid growth phase early in development, embryos may utilize similar programs to maintain a growth-permissive metabolism. Dissecting the genetic underpinnings of embryonic metabolism would likely provide important insights into the nutrient uptake programs that are co-opted in cancer. While loss of function studies in the early embryo would help define the metabolic roles of oncofetal genes in their physiologic context, classical *in vivo* metabolic assays are difficult to perform in embryos. *Lin28a* and *Lin28b* are oncofetal genes, and thus highly expressed in early embryogenesis and then silenced in most adult tissues, but reactivated in cancer (Yang and Moss, 2003; Viswanathan et al., 2009). Cancer cells may utilize the embryonic function of *Lin28a/b* to drive a metabolic shift towards increased glucose uptake and glycolysis – a phenomenon termed the “Warburg effect.” Previously, we showed that *Lin28a* expression promotes glycolytic metabolism in muscle *in vivo* and in C2C12 myoblasts *in vitro* (Zhu et al., 2010). Though we cannot yet readily determine the metabolic effects of shutting off *Lin28a/b* within the embryo, we have dissected the potent effects of reactivating and inactivating this oncofetal program in adults. Conversely, in normal adult tissues that do not express high levels of *Lin28a* or *Lin28b*, one might ask if a role for the highly abundant *let-7* is to lock cells into the metabolism of terminally differentiated cells to prevent aberrant reactivation of embryonic metabolic programs. Further studies are required to understand how this pathway may link mechanisms of tumorigenesis and diabetogenesis.

Our report implicates *Lin28a/b* and *let-7* as important modulators of glucose metabolism through interactions with the insulin-PI3K-mTOR pathway and T2D-associated genes identified in GWAS. Although it is likely that additional mechanisms and feedback loops exist, our data suggests a model whereby *Lin28a/b* and *let-7* coordinate the GWAS identified genes and the insulin-PI3K-mTOR pathway to regulate glucose metabolism (Figure 6E). It also suggests that enhancing *Lin28* function or abrogating *let-7* may be therapeutically promising for diseases like obesity and diabetes. Likewise, results from this work might shed light on the physiology of aging and, specifically, how the accumulation of *let-7* in aging tissues may contribute to the systemic insulin resistance that accompanies aging.

EXPERIMENTAL PROCEDURES

Mice

All animal procedures were based on animal care guidelines approved by the Institutional Animal Care and Use Committee. Mouse lines used in this study are described in the Extended Experimental Procedures and Figure S5.

Indirect Calorimetry

The apparatus used was a set of 16 OxyMax® Metabolic Activity Monitoring chambers (Columbus Instruments; Columbus, OH, USA). Each chamber consisted of a self-contained unit capable of providing continuous measurements of an individual mouse's total activity and feeding behavior. Monitoring occurred over a 3-day period. Each subject was placed into an individual chamber on day 1, with free access to food and water during the course of the experiment. Subjects were maintained under a normal 12:12 h light:dark cycle. All measurements were sampled periodically (at approximately 12-min intervals) and

automatically recorded via the OXYMAX Windows V3.22 software. Activity measures over the final 24-h period were parceled into 2-h bins and these were used to express diurnal activity levels.

Quantitative RT-PCR

Performed with standard methods, which are described in detail in the Extended Experimental Procedures.

Histology

Tissue samples were fixed in 10% buffered formalin or Bouin's solution and embedded in paraffin.

Glucose and insulin tolerance tests

Overnight-fasted mice were given i.p. glucose (2 mg/g body weight). For insulin tolerance test, 5 hour fasted mice were given 0.75 U insulin/kg body weight by i.p. injection (Humulin). Blood glucose was determined with a Lifescan One Touch glucometer. Insulin, GH, and Igf1 levels were measured by ELISA (Crystal Chem).

Cloning

Murine *Lin28a* and human *LIN28B* cDNA was subcloned into pBabe.Puro and pMSCV.Neo retroviral vectors. *LIN28B* and Control shRNA in lentiviral plasmids were purchased from Sigma-Aldrich and previously reported in Viswanathan et al., 2009. UTR cloning for luciferase reporters is described in Supplemental Table S2.

Cell culture, viral production, and transfection

Performed using standard methods as described in the Extended Experimental Procedures.

Glucose uptake assay

In vitro glucose uptake assays were performed as described in Berti and Gammeltoft, 1999.

Drug treatments

Rapamycin was injected i.p. 3 times a week for mouse experiments. For cell culture, C2C12 myotubes differentiated for 3 days were incubated with inhibitors for 1 day prior to glucose uptake assays. See Extended Experimental Procedures for further details.

Western blot assay

Performed using standard methods. Detailed methods and reagents used are described in the Extended Experimental Procedures.

Luciferase reporter assay

10 ng of each construct was co-transfected with 10 nM miRNA duplexes or into HEK-293T cells in a 96-well plate using lipofectamin-2000 (Invitrogen). After 48 hours, the cell extract was obtained; firefly and *Renilla* luciferase activities were measured with the Promega Dual-Luciferase[®] reporter system.

MAGENTA analysis

See Results, Table 1 Legend, and Extended Experimental Procedures for detailed methods.

Statistical analysis

Data is presented as mean \pm SEM, and Student's t-test (two-tailed distribution, two-sample unequal variance) was used to calculate *p* values. Statistical significance is displayed as *p* < 0.05 (one asterisk) or *p* < 0.01 (two asterisks). The tests were performed using Microsoft Excel where the test type is always set to two-sample equal variance.

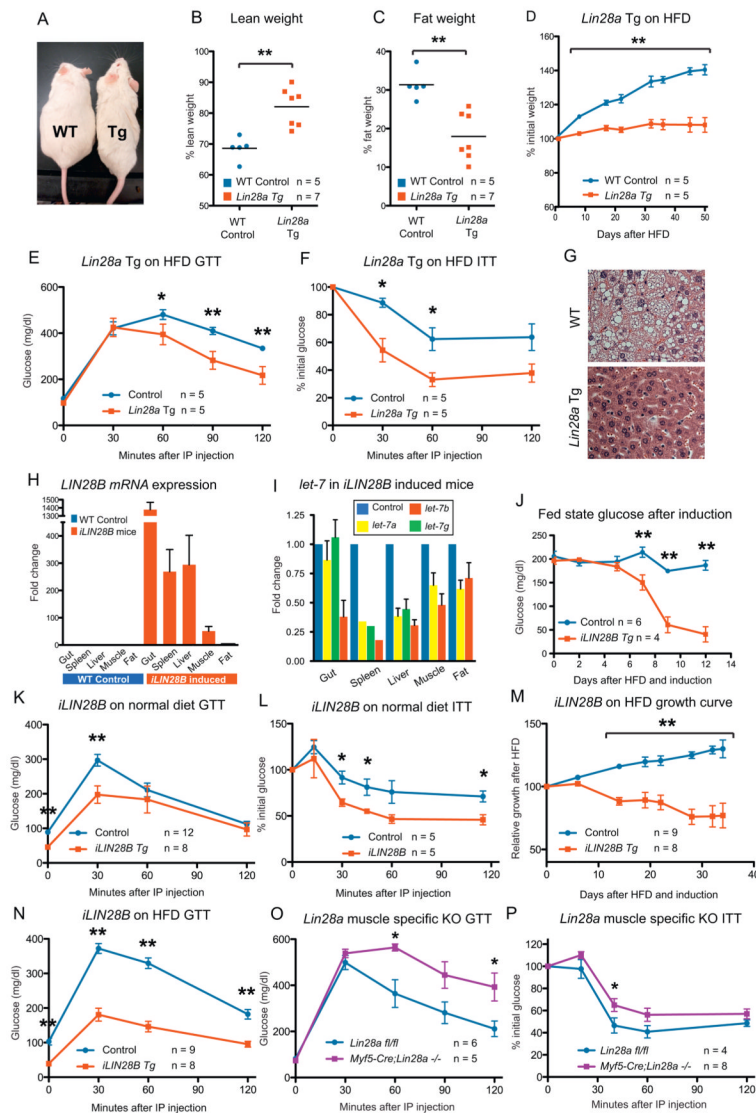

Figure 1. *Lin28a* Tg and *iLIN28B* Tg mice are resistant to obesity and diabetes and *Lin28a* is physiologically required for normal glucose homeostasis
 (A) Aged wild-type (left) and *Lin28a* Tg mice (right) fed a normal diet, at 20 weeks of age.
 (B) Percentage body fat and (C) lean mass as measured by DEXA.
 (D) Weight curve of mice fed a HFD containing 45% kcals from fat.
 (E) Glucose tolerance test (GTT) and (F) Insulin tolerance test (ITT) of mice on HFD.
 (G) Liver histology of mice fed HFD.
 (H) Human *LIN28B* mRNA expression in a mouse strain with dox inducible transgene expression (named *iLIN28B*).
 (I) Mature *let-7* expression in gut, spleen, liver, muscle and fat.
 (J) Kinetics of fed state glucose change after induction.
 (K) GTT and (L) ITT under normal diets.
 (M) *iLIN28B* growth curve under HFD.
 (N) GTT after 14 days of HFD and induction.
 (O) GTT and (P) ITT of *Myf5-Cre; Lin28a^{fl/fl}* mouse.

Controls for Lin28a Tg mice are WT. Controls for iLIN28B Tg mice carry only the LIN28B transgene. Controls for muscle knockout mice are Lin28a^{fl/fl} mice. The numbers of experimental animals are listed within the charts.

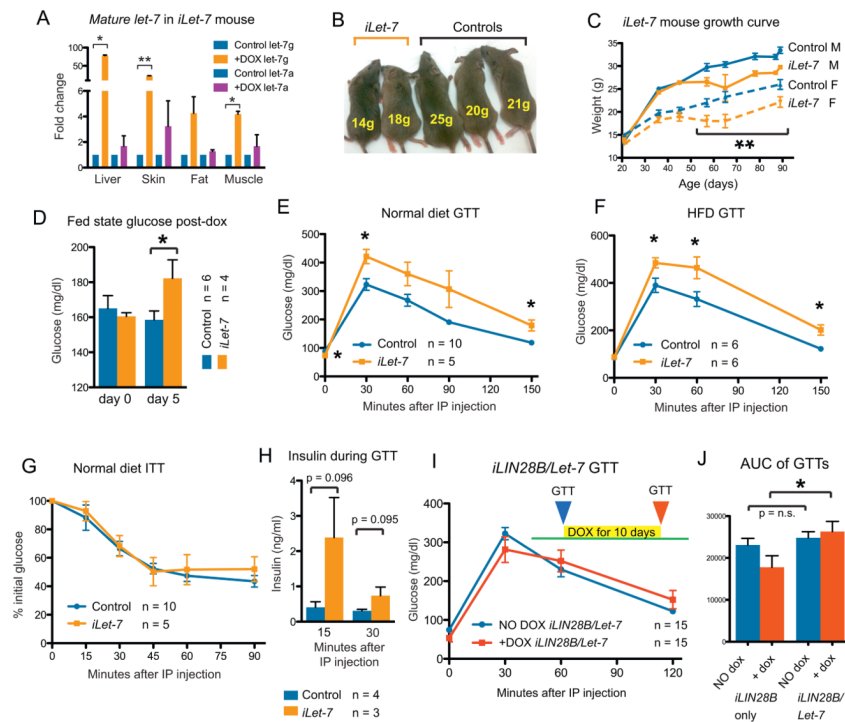

Figure 2. *iLet-7* mice are glucose intolerant

(A) *let-7g* and *let-7a* qRT-PCR in tissues of dox induced *iLet-7* mice (n = 3) and controls (n = 3).

(B) Reduced size of induced animals.

(C) *iLet-7* growth curve for males and females.

(D) Fed state glucose in *iLet-7* mice induced for 5 days.

GTTs performed on mice fed with either (E) normal diet or (F) HFD.

(G) ITT on normal diet.

(H) Insulin production during a glucose challenge.

(I) GTT of *LIN28B/Let-7* compound heterozygote mice before (blue) and after (red) induction with dox.

(J) Area under the curve (AUC) analysis for this GTT.

Controls for *iLet-7*Tg mice carry either the *Let-7* or *Rosa26-M2rtTa* transgene only. The numbers of experimental animals are listed within the charts.

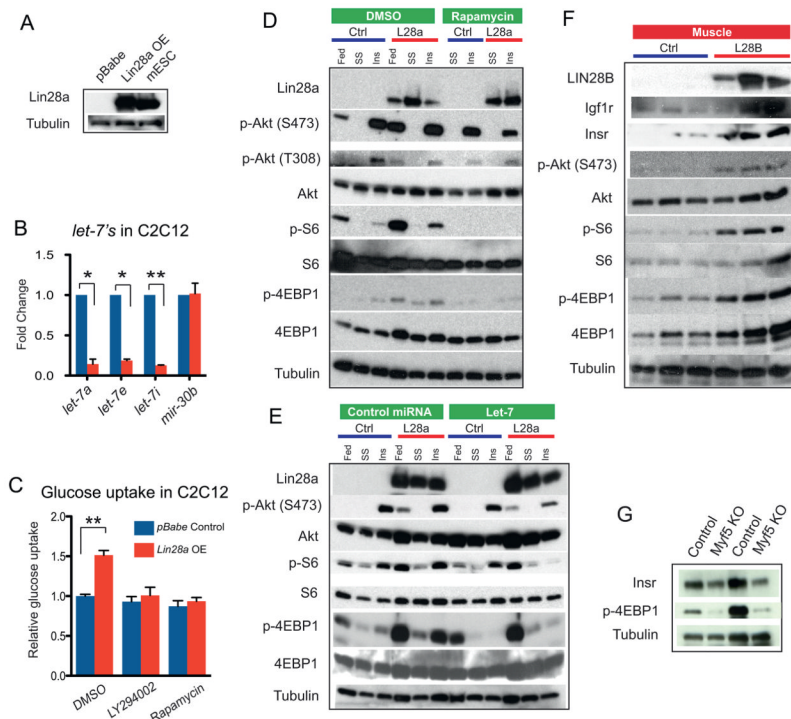

Figure 3. Insulin-PI3K-mTOR signaling is activated by Lin28a/b and suppressed by let-7

(A) Western blot analysis of Lin28a protein expression in C2C12 myoblasts infected with control pBabe or *Lin28a* overexpression vector, and mouse ESCs, with tubulin as the loading control.

(B) Quantitative PCR for *let-7* isoforms in C2C12 myoblasts, normalized to *sno142*, after *Lin28a* overexpression.

(C) 2-deoxy-D- ^3H glucose uptake assay on 3-day-differentiated C2C12 myotubes with and without *Lin28a* overexpression, treated with DMSO, the PI3K inhibitor LY294002, and the mTOR inhibitor rapamycin for 24 hrs.

(D) Western blot analysis of the effects of *Lin28a* overexpression on PI3K-mTOR signaling in C2C12 myoblasts, under serum-fed (fed), 18 hr serum starved (SS) or insulin-stimulated (Ins) conditions. Insulin stimulation was performed in serum-starved myoblasts with 10 $\mu\text{g}/\text{mL}$ insulin for 5 min. Prior to insulin stimulation, serum-starved myoblasts were treated with either DMSO or 20 ng/mL rapamycin for 1 hr.

(E) Western blot analysis of the effects of *let-7f* or control miRNA on PI3K-mTOR signaling in C2C12 myoblasts under serum-fed (fed), 18 hr serum starved (SS) or insulin-stimulated (Ins) conditions.

(F) Western blot analysis of the effects of *LIN28B* induction by dox on PI3K-mTOR signaling in quadriceps muscles *in vivo* ($n = 3$ *iLIN28B* Tg mice and 3 *LIN28B* Tg only mice).

(G) Insr and p-4EBP1 protein levels in wild-type and *Lin28a* muscle-specific knockout adults.

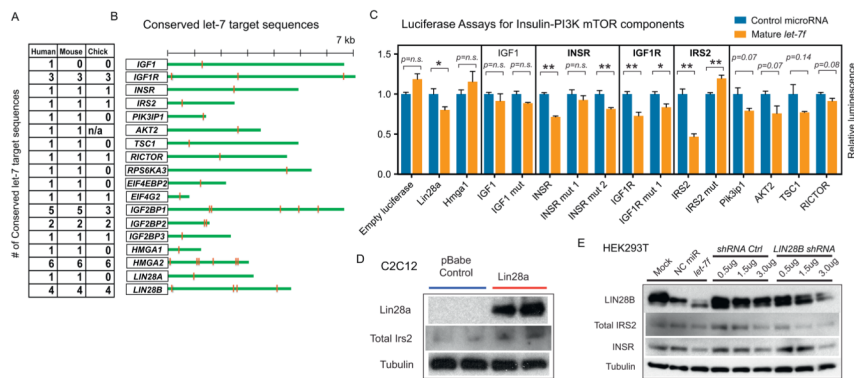

Figure 4. Lin28a/b and let-7 regulate genes in the insulin-PI3K-mTOR pathway
 (A) Shown are the numbers of conserved *let-7* binding sites within 3' UTRs found using the TargetScan algorithm.
 (B) Putative *let-7* binding sites in 16 genes of the insulin-PI3K-mTOR pathway and in *Lin28a/b*.
 (C) 3' UTR luciferase reporter assays performed to determine functional *let-7* binding sites. Bar graphs show relative luciferase reporter expression in human HEK293T cells after transfection of mature *let-7* duplex normalized to negative control miRNA. Shown also are mutations in the seed sequence of the *let-7* binding sites for *INSR*, *IGF1R* and *IRS2*.
 (D) Western blot analysis of Lin28a, Irs2, and tubulin in C2C12 myoblasts with and without Lin28a overexpression.
 (E) Western blot analysis of LIN28B, total IRS2, INSR and TUBULIN in HEK293T cells with either *let-7f* transfection or shRNA knockdown of *LIN28B*.

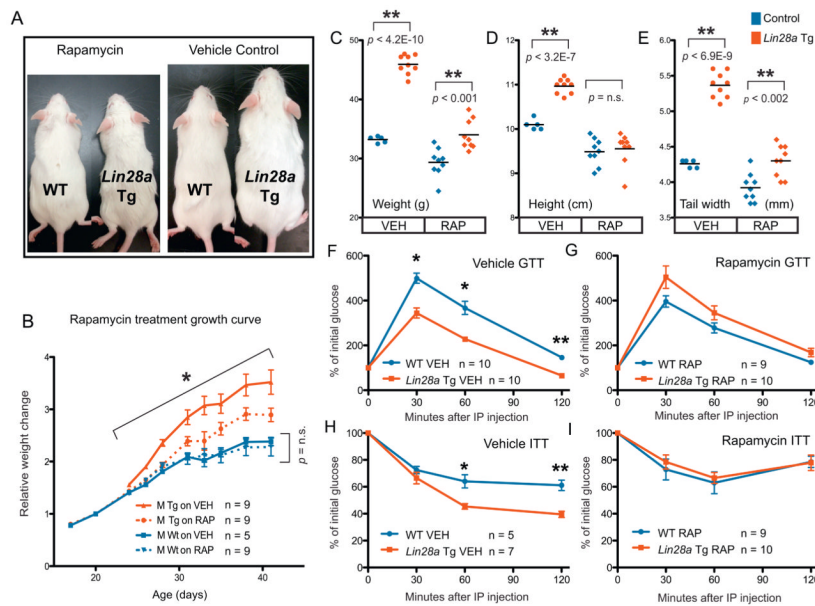

Figure 5. mTOR is required for *Lin28a*'s effects on growth and glucose metabolism in vivo
 (A) Rapamycin (left 2 mice) and vehicle (right 2 mice) treated wild-type and *Lin28a* Tg mice shows relative size differences.
 (B) Curves showing relative growth (normalized to weight on first day of treatment) for mice treated from 3 weeks to 6.5 weeks of age. Blue and red represent wild-type and *Lin28a* Tg mice, respectively. Solid and dotted lines represent vehicle and rapamycin treated mice, respectively. Growth was measured by several other parameters:
 (C) weight, (D) crown-rump length or height, and (E) tail width.
 (F) GTT performed after 2 doses of vehicle or (G) rapamycin.
 (H) ITT performed after 1 dose of vehicle or (I) rapamycin.
 Controls for *Lin28a* Tg mice are WT. The numbers of experimental animals are listed within the charts.

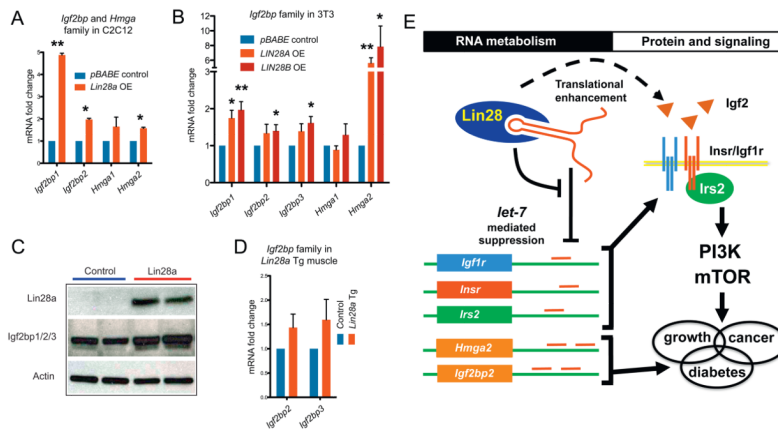

Figure 6. let-7 target genes are associated with Type 2 diabetes mellitus and a model of the Lin28/let-7 pathway in glucose metabolism
 mRNA expression of Igf2bp and Hmga family members in (A) C2C12 with and without Lin28a overexpression and in (B) 3T3 cells with and without LIN28A or LIN28B overexpression.
 (C) Western blot of NIH 3T3 cells with Lin28a overexpression showing Lin28a and Igf2bp1/2/3 protein levels (n = 3 biological replicates).
 (D) Igf2bp2 and Igf2bp3 mRNA in Lin28a Tg muscle.
 (E) Model of Lin28/let-7 pathway in glucose metabolism.

Table 1
MAGENTA analysis of T2D and fasting glucose associations in different *let-7* target gene set definitions

The statistical enrichment for genes associated with T2D and fasting glucose among *let-7* targets using the MAGENTA algorithm. The TargetScan algorithm was used to define the “All human *let-7* targets” and the “Conserved *let-7* targets” gene sets (<http://www.targetscan.org/>). mRNAs downregulation following *let-7* overexpression (OE) was measured in primary human fibroblasts (Legesse-Miller et al., 2009), and protein downregulation following *let-7* OE was measured in HeLa cells (Selbach et al., 2008). The enrichment cutoff used is the 75th percentile of all gene association scores in the genome. The enrichment fold is the ratio between the observed and expected number of genes above the enrichment cutoff. Genes linked to validated GWAS SNPs (39 SNPs for T2D and 14 SNPs for fasting glucose) were ordered according to the number of target gene sets they appear in and then alphabetically.

<i>let-7</i> target gene set	# genes analyzed [†]	Nominal enrichment <i>p</i> -value	Expected # genes above enrichment cutoff	Observed # genes above enrichment cutoff	Enrichment fold	# genes linked to validated GWAS SNPs	Genes linked to validated GWAS SNPs
Type 2 diabetes (DIAGRAM+ meta-analysis)							
All targets predicted by <i>TargetScan</i>	1763	0.036	441	462	1.05	14	IGF2BP2, DUSP9, SLC5A6, TP53INP1, YKT6, ZNF512, HMG2, KCNJ11, MAN2A2, MEST, NOTCH2, ZNF275, FAM72B, RCCD1
Conserved targets predicted by <i>TargetScan</i>	789	0.089	197	212	1.08	7	IGF2BP2, DUSP9, SLC5A6, HMG2, KCNJ11, MAN2A2, ZNF275
Downregulated mRNAs following <i>let-7</i> OE	795	0.055	199	216	1.09	9	IGF2BP2, DUSP9, SLC5A6, TP53INP1, YKT6, ZNF512, HHEX, IRS1, TLE4
Downregulated mRNAs following <i>let-7</i> OE + <i>TargetScan</i>	502	0.061	126	140	1.11	6	IGF2BP2, DUSP9, SLC5A6, TP53INP1, YKT6, ZNF512
Downregulated proteins following <i>let-7</i> OE	97	1.0E-06*	24	46	1.92	2	IGF2BP2, CDKAL1
Downregulated proteins following <i>let-7</i> OE + <i>TargetScan</i>	37	0.011	9	16	1.78	1	IGF2BP2
Fasting glucose (MAGIC meta-analysis)							
All targets predicted by <i>TargetScan</i>	1708	0.015	427	450	1.05	3	CRY2, SLC2A2, GLIS3
Conserved targets predicted by <i>TargetScan</i>	759	0.042	190	207	1.09	1	CRY2
Downregulated mRNAs following <i>let-7</i> OE	750	1.0E-04*	188	226	1.20	2	CRY2, FADS1

<i>let-7</i> target gene set	# genes analyzed [†]	Nominal enrichment <i>p</i> -value	Expected # genes above enrichment cutoff	Observed # genes above enrichment cutoff	Enrichment fold	# genes linked to validated GWAS SNPs	Genes linked to validated GWAS SNPs
Downregulated mRNAs following <i>let-7</i> OE + <i>TargetScan</i>	484	0.013	121	141	1.17	1	CRY2
Downregulated proteins following <i>let-7</i> OE	96	0.632	24	23	0.96	0	-
Downregulated proteins following <i>let-7</i> OE + <i>TargetScan</i>	35	0.245	9	11	1.22	0	-

[†]The following genes were removed from the analysis: (i) genes absent from the full human gene list used in the analysis, (ii) genes that had no SNPs within 110 kb upstream or 40 kb downstream to their most extreme transcript boundaries, or (iii) to correct for potential inflation of enrichment due to physical proximity of *let-7* target genes along the genome, subsets of proximal genes assigned the same best local SNP were collapsed to one gene and assigned the score of the most significant gene *p*-value in that subset.

* gene sets that pass a Bonferroni corrected cutoff ($p < 0.004$).
