Abstract

Protein-protein interactions (PPIs) mediated by the polo-box domain (PBD) of polo-like kinase 1 (Plk1) serve important roles in cell proliferation. Critical elements in the high affinity recognition of peptides and proteins by PBD are derived from pThr/pSer-residues in the binding ligands. However, there has been little examination of pThr/pSer mimetics within a PBD context. Our current paper compares the abilities of a variety of amino acid residues and derivatives to serve as pThr/pSer replacements by exploring the role of methyl functionality at the pThr β–position and by replacing the phosphoryl group by phosphonic acid, sulfonic acid and carboxylic acids. This work sheds new light on structure activity relationships for PBD recognition of phosphoamino acid mimetics.

Keywords

Plk1; polo-like kinase; polo-box domain; phosphoamino acid mimetic

1. Introduction

The central roles that protein-protein interactions (PPIs) play in biochemical processes^{1,2} and their frequent reliance on binding "hot spots" $3-6$ have made them attractive therapeutic targets.7–14 Many components of cellular signal transduction employ sub-classes of PPIs that involve the recognition of either phosphotyrosyl (pTyr) or phosphothreonyl (pThr)/ phosphoserine (pSer)–containing sequences.15–19 Because phosphoryl groups serve as key elements of high affinity interactions, these phospho-dependent PPIs are potentially amenable to disruption by small-to-moderate size molecules.

The polo-like kinases (Plks) are a subfamily of serine-threonine kinases that play critical roles in cellular proliferation.20–24 Of the known Plks (Plk1 – Plk5), Plk1 has been identified

as an anticancer target due to its ability to promote tumorigensesis. $25-27$ In addition to its catalytic domain, Plk1 contains a C-terminal polo-box domain (PBD), which recognizes pThr/pSer-containing sequences and directs the enzyme to specific sub-cellular locations.²⁸ While significant effort has been devoted to developing inhibitors targeting the catalytic activity of Plk1, $29-36$ targeting the PBD may afford an alternative PPI-directed approach to down-regulating Plk1 function.25,37–43

The five-mer peptide "Pro-Leu-His-Ser-pThr" (**1**, Figure 1) represents a high affinity PBDbinding sequence derived from the pT78 region of the polo-box interacting protein 1 (PBIP1), which offers a starting point for the design of PBD-directed inhibitors.³⁸ Although the phosphoryl moiety provides an essential PBD recognition motif, it presents particular challenges to bioavailability due to its dianionic charge and the lability of the phosphoryl ester bond to phosphatases. Similar problems are also encountered in the development of inhibitors directed against pTyr-binding domains. However, unlike the latter family of compounds, for which a large number of p Tyr mimetics have been examined, $44,45$ significantly fewer pThr/pSer mimetics have been reported.^{46–50} Our current paper reports the synthesis and PBD-binding affinities of peptides containing a variety of pThr/pSer mimetics, many of which have not yet been examined within the context of PBD-binding peptides.

2. Results and discussion

2.1 Design of phosphomimetic-containing peptides

Recently, we discovered that introduction of long-chain arylalkyl groups onto the δ^1 nitrogen (N3) of the histidine imidazole ring of parent peptide **1** could significantly increase Plk1 PBD-binding affinity.⁴² From the X-ray co-crystal structure of a high affinity peptide containing a $C_6H_5(CH_2)_8$ –His adduct (2a, Figure 1), we found that the potency enhancement occurred through new binding interactions in a previously occluded hydrophobic channel on the PBD surface. Although our original His-adduct-containing peptides were obtained in small quantities as synthetic by-products, we devised a route to synthesize protected δ^1 - alkyl-containing amino acid analogues of type **3** (Figure 2) that allowed direct Fmoc-based solid-phase synthesis His-modified peptides such as **2a**. ⁵¹ In our current study, we replaced the pThr phosphate group in **2a** with phosphonic acid (**2b**), sulfonic acid (**2c**) and carboxylic acid (**2d**) functionality. We also replaced the pThr residue with pSer (**2e**), the β,β-bis-methyl variant of pSer (**2f**) and p(allo-Thr) (**2g**) as well as with Glu (**2h**), Gln (**2i**) and Asp (**2j**) residues (Figure 1) and determined their Plk1 PBD binding affinities.

2.2 Preparation of protected amino acid analogues and their use in solid-phase peptide synthesis

Peptides **2a** – **2k** were prepared by solid-phase techniques using Fmoc-based protocols. The C-terminal residues of peptides $2a - 2g$ were incorporated using the protected amino acid analogues **4a** – **4g**, respectively (Figure 2). Commercially-available monobenzyl phosphoryl esters (**4a**, **4e** and **4g**) were used to introduce pThr, pSer and p(allo-Thr) respectively. Reagent **4b**, which was used to introduce the (2S, 3R)-2-amino-3-methyl-4 phosphonobutyric acid (Pmab) residue, was prepared according to literature procedures.⁵⁰ The remaining amino acid analogues (**4c**, **4d** and **4f**) were synthesized as outlined below.

2.2.1 Preparation of *N***-Fmoc (2***S***,3***R***)-2-amino-3-methyl-4-((2,2,2-**

trichloroethoxy)sulfonyl)butanoic acid (4c)—Preparation of peptide **2c**, containing the sulfonic acid-based pThr mimetic, (2S, 3R)-2-amino-3-methyl-4-sulfonylbutanoic acid (Smab), was achieved using reagent **4c**, which has a sulfonic acid moiety. Mitsunobu

treatment of known **5** ⁵⁰ with thioacetic acid, triphenylphosphane, and diisopropyl diazodicarboxylate (DIAD) in dry THF gave **6** in good yield (Scheme 1). The N-benzyl carbamate group of **6** was converted to acetyl amide (**7**) using sodium iodide and acetyl chloride. Oxidative chlorination of **7** to the corresponding sulfonyl chloride was achieved in good yield using N-chlorosuccinimide (NCS) in aqueous HCl – MeCN 52 and this was followed by treatment with aqueous sodium hydroxide to provide the free sulfonic acid (**8**). Finally, removal of N-acetyl and O-methyl groups by refluxing in 6N HCl yielded the free amino acid, which was converted to the N-Fmoc-protected **4c** using Fmoc-OSu (Scheme 1).

2.2.2 Preparation of *N***-Fmoc (***2S,3S***)-2-amino-5-(***tert***-butoxy)3-methyl-5-**

oxoentanoic acid (4d)—Introduction of the C-terminal pThr mimicking residue in peptide **2d** employed the protected amino acid **4d**. The synthesis of **4d** is shown in Scheme 2. Conversion of the protected D-serine analogue **9** to **14** was according to literature procedures (Scheme 2).53 Compound **14** was first converted from the ethyl ester to the benzyl ester (**15**) and then subjected to Jones' oxidation to afford the protected amino acid **16**. The desired reagent **4d** was obtained by removing the N-Boc group (4M HCl in dioxane) and installing the N- Fmoc group (Fmoc-OSu) (Scheme 2).

2.2.3 Preparation of *N***-Fmoc (***2S***)-2-amino-3-(benzyloxyphosphoryloxy)-3 methylbutanoic acid (4f)—**The preparation of phosphopeptide **2f** employed the protected amino acid **4f**, which was prepared as shown in Scheme 3. Grignard reaction of **10** with MeMgI in diethyl ether at 0 °C proceeded to give **17**, which was converted to **18** by oxidation with Jones' reagent in acetone at 0 °C.54 Compound **18** was converted to its allyl ester and then the N-Boc group was exchanged for N-Fmoc protection (**19**) by first deprotecting using 1M HCl and then reacting with Fmoc-Osu. Following a similar strategy as previously reported for the synthesis of **4a**, ⁵⁵ **19** was converted first to the dibenzyl ester (**20**) and then to the desired reagent **4f** (Scheme 3).

2.3 Plk1 PBD-binding affinities of peptides 2a – 2k

2.3.1 Dianionic species—We determined the Plk1 PBD binding affinities using an ELISA-based 96-well assay that measured the ability of the synthetic peptides to compete with support-bound pT78-derived phosphopeptide for binding to Plk1 expressed in mitotic 293A cell lysates.38,42 Results are shown in Figures 3 and 4. As previously reported, addition of the $C_6H_5(CH_2)_8$ -group to the histidine δ^1 -nitrogen (peptide 2a) significantly enhanced binding affinity relative to the parent parent peptide **1** (Figure 3). We first examined dianionic functionality. Consistent with previous results, $38,42,43,50$ high affinity was maintained when pThr was replaced by Pmab- (compare peptide **2a** with **2b**, Figure 3). This indicates that the phosphoryl ester oxygen in the pThr residue is not a critical component of recognition.

Next, we directed our attention toward modifying the 3-position of pThr. We observed that deletion of the (3R)-methyl group to give pSer (peptide **2e**) resulted in an approximate order-of-magnitude loss of affinity (Figure 3). This was in agreement with previous work that had shown an approximate 7-fold preference for pThr over pSer.⁵⁶ However, it should be noted that high affinity pSer-containing peptides are known that include a Pro residue Cterminal to the pSer.57 Placement of a second methyl group at the 3-position (**2f**) led to a further loss of potency, but the 3,3-dimethyl analogue did retain moderately good affinity. In contrast, reversal of the pThr stereochemistry at the 3-position (p-alloThr, **2g**), resulted in a nearly three orders-of-magnitude loss of affinity. The relatively good affinities of the desmethyl (pSer, **2e**) and dimethyl (**2f**) analogues indicate that both the absence of the (3R) methyl and the presence of a pro-(3S)-methyl are tolerated within the binding pocket.

Therefore, the dramatic loss of affinity observed with **2g** may be related to unfavorable conformational geometries of the p-alloThr residue.

2.3.2 Monoanionic and uncharged species—Unlike SH2 domains, in which recognition of tyrosyl phosphates involves salt bridges between both anionic phosphoryl oxygens and two conserved Arg residues,⁵⁸ interaction of the PBD with the pThr phosphoryl group of **2a** involves only a single salt bridge with Lys540 (PBD accession code 3RQ742). Additional PBD-phosphoryl interactions are hydrogen bonding in nature (with His538 and several water molecules). Therefore, while SH2 domain-directed pTyr mimetics often require maintenance of dianionic character for high affinity binding,⁴⁵ it may be reasonable to expect that a single anionic charge could be sufficient for ligands to bind with high affinity to PBD domains. The Smab-containing peptide (**2c**) can be viewed as a monoanionic isostere of Pmab-containing **2b**, in which a sulfonic acid moiety is employed rather than a phosphonic acid group. Sulfonic acids are known as monoanionic phosphoryl mimetics.59,60 However, peptide **2c** exhibited almost four orders-of-magnitude loss of affinity relative to the reference peptide **2a** (Figure 4). This unexpectedly large shift to the right in Figure 4 resulted in **2c** binding less efficaciously than peptide **1**, in which the Hisadduct group is lacking.

Carboxylic acids can serve as monoanionic phosphoryl mimetics in a number of physiological contexts. Aryl-containing carboxylic acids have shown widespread value in the design of constructs targeting p Tyr-dependent interactions.⁴⁴ Glutamic acid has a side chain length that places its carboxylic acid group at a distance from the α-carbon that approximates the phosphoryl groups of both pSer (for example, see $61-67$) and pThr (for example, see $^{61,68-71}$). Although the side chain length of Asp situates its carboxylic acid closer to the α-carbon than Glu, it has also frequently been used as a pSer mimetic (for example, \sec^{62-67}). In our current work, we observed that the Glu-containing peptide (2h) bound with affinity equivalent to the sulfonic acid-containing **2c**. This is somewhat unexpected, since the Smab residue in **2c** exhibits greater structural similarity to pThr (or Pmab) than does **2h**. The Asp-containing peptide (**2j**) bound with slightly less affinity than **2h** and the uncharged Gln-containing peptide (**2i**) bound nearly as well as **2j**. Based on the results presented in Figure 3 showing that a (3R)-methyl group enhances the binding of phosphate-containing species, we anticipated that a $(3R)$ -methyl-containing Glu residue should serve as a better pThr mimetic than unmodified Glu. Therefore, it was surprising to find that introduction of a (3R)-methyl group onto the Glu residue in **2h** resulted in a significant loss of affinity (peptide **2d,** Figure 4). Peptide **2d** bound with even less affinity than the non-phosphorylated peptide (**2k**), which contained no phosphoryl-mimicking functionality.

The differences in binding affinities of mono-anionic and uncharged species discussed above are minor in comparison to their shared greater than three orders-of-magnitude loss of affinity when compared to the parent pThr-containing peptide **2a**. None of the sulfur or carbon-based phosphoryl mimetics was as effective as even the least potent phosphorusbased analogue (**2g**). It was noteworthy that 3-methyl functionality can play an important role on binding recognition of phosphoryl-containing species.

Our reasoning in selecting platform **2** as a display vehicle relied on the high affinity of the parent peptide **2a**, which is approximately three orders-of-magnitude greater than **1**. This added affinity reflects extended ligand-protein interactions outside the pThr binding pocket that are afforded by the $C_6H_5(CH_2)_8$ -His adduct moiety. These interactions could potentially lessen the relative importance of binding within the pThr pocket. For example, while the non-phosphorylated version of **1** (PLHST) exhibits near negligible affinity, the corresponding non-phosphorylated form of **2** (peptide **2k**) displays measurable affinity

arising from a shift to the left in its binding curve that is consistent with the shift seen in going from **1** to **2a** (Figure 4). It should also be noted that X-ray co-crystal data show that the binding orientation of $2a$ is nearly superimposable with $1.^{42}$ Therefore, the unexpected SAR data for certain series-**2** pThr mimetics potentially indicate that something unexpected may be going on in the pThr binding pocket: Just what this "something" is, is not clear. In spite of these uncertainties, the current work represents the first report of PBD binding affinities of peptides containing a series of pThr/pSer mimetics. The SAR parameters derived from our work may be of value in the further design of Plk1 PBD-binding peptides, including those that do not contain the unusual His-adduct moiety.

3. Experimental

3.1. General experimental

All experiments involving moisture-sensitive compounds were conducted under dry conditions (positive argon pressure) using standard syringe, cannula, and septa apparatus. Solvents: All solvents were purchased anhydrous (Aldrich) and used directly. HPLC-grade hexanes, EtOAc, CH_2Cl_2 , and MeOH were used in chromatography. TLC: analytical TLC was performed on Analtech pre-coated plates (Uniplate, silica gel GHLF, 250 microns) containing a fluorescence indicator; NMR spectra were recorded using a Varian Inova 400 MHz spectrometer. Coupling constants are reported in Hertz, and peak shifts are reported in δ (ppm) relative to TMS. Low-resolution mass spectra (ESI) were measured with an Agilent 1200 LC/MSD-SL system. High resolution, accurate mass measurements for confirmation of elemental compositions were obtained by positive ion, ESI analysis on a Thermo Scientific LTQ-XL Orbitrap mass spectrometer with HPLC sample introduction using a short narrow-bore C_{18} reversed-phase column and standard CH_3CN/H_2O gradient. Reported m/z values are the average of 8 or more scans over the chromatographic peak of interest.

3.2. Synthesis of *N***-Fmoc-(***2S, 3R***)-2-aminuteso-3-methyl-4-sulfobutanoic acid 4c from 5**

3.2.1. (2S, 3R)-methyl *N***-Cbz-2-aminuteso-3-methyl-4-acetylthio-butanoate (6) —**Starting from readily prepared aminuteso acid **5** ⁵⁰ DIAD (0.95 mL, 4.83 mmol) was added at 0 °C under dry nitrogen to a solution of triphenylphosphine (1.27 g, 4.83 mmol) in dry THF (15 mL) in a flame-dried round-bottomed flask, and the mixture was stirred until a white solid appeared. Stirring was continued for 10 minutes at 0 °C, after which compound **5** (0.68 g, 2.42 mmol) in dry THF (5 mL) was added. After the mixture had been stirred for 45 minutes, thioacetic acid (0.35 mL, 4.83 mmol) was added and stirring was continued for 3 h. Diethyl ether was added, and the mixture was washed with H2O, followed by drying of the organic layer over $MgSO₄$. The mixture was filtered and concentrated. The final residue was purified by silica gel column chromatography (EtOAc: hexanes; from 1: 10 to 1: 2) to afford product $\bf{6}$ (0.8 g) as s colorless gum (98%). [\bf{a}] \bf{b}^{18} 24.6 (c 0.77, CHCl3); ¹H NMR $(400 \text{ MHz}, \text{CDCl}_3)$ δ 7.39 – 7.27 (m, 5H), 5.62 (d, $J = 8.0 \text{ Hz}$, 1H), 5.10 (s, 2H), 4.40 (dd, JI $= 8.0$ Hz, $J2 = 4.0$ Hz, 1H), 3.75 (s, 3H), 3.04 (dd, $J1 = 12.0$ Hz, $J2 = 8.0$ Hz, 1H), 2.68 (dd, $JI = 12.0$ Hz, $J2 = 8.0$ Hz, 1H), 2.32 (s, 3H), 2.76 – 2.12 (m, 1H), 1.00 (d, $J = 8.0$ Hz, 3H); 13C NMR (100 MHz, CDCl3) δ 195.6, 171.9, 156.2, 136.3, 128.6, 128.2, 67.2, 57.7, 52.4, 37.2, 31.7, 30.6, 16.3; ESI-MS calcd for $C_{16}H_{22}NO_5S (M+H)^+$: 340.1, found: 340.1.

3.2.2. (*2S, 3R***)-Methyl** *N***-acetyl-2-amino-3-methyl-4-acetylthio-butanoate (7)—**

To a mixture of the **6** (0.322g, 0.95 mmol) and sodium iodide (1.42g, 9.49 mmol) in dry acetonitrile (19 mL) was slowly added at 0° C acetyl chloride (0.67 mL, 9.49 mmol). The resulting mixture was heated at 60 °C for 7 h with stirring under a nitrogen atmosphere. After addition of saturated aqueous sodium hydrogen sulfite and saturated aqueous sodium hydrogen carbonate with ice cooling, the mixture was thoroughly extracted with chloroform. The extract was washed with brine, dried over potassium carbonate, and evaporated under

reduced pressure. Purification of the product using silica gel column chromatography (EtOAc: hexanes; from 1: 2 to 2: 1) gave the product **7** (0.2 g) as a white foam (85%). $[\alpha]_D^{18}$ 30.14 (c 0.75, CHCl3); ¹H NMR (400 MHz, CDCl₃) δ 6.34 (d, *J* = 8.0 Hz, 1H), 4.60 (dd, $JI = 12.0$ Hz, $J/2 = 8.0$ Hz, 1H), 3.76 (s, 3H), 3.08 (dd, $JI = 16.0$ Hz, $J/2 = 8.0$ Hz, 1H), 2.62 (dd, $JI = 16.0$ Hz, $J/2 = 8.0$ Hz, 1H), 2.34 (s, 3H), 2.24 – 2.10 (m, 1H), 2.07 (s, 3H), 1.00 (d, $J = 8.0$ Hz, 3H); ¹³C NMR (100 MHz, CDCl₃) δ 196.3, 172.2, 170.3, 55.9, 52.5, 37.4, 32.0, 30.7, 23.4, 16.7; ESI-MS calcd for $C_{10}H_{18}NO_4S$ (M+H)⁺: 248.1, found: 248.1.

3.2.3. *N***-Fmoc-(***2S, 3R***)-2-aminuteso-3-methyl-4-sulfobutanoic acid (4c)—**At 0

 $^{\circ}$ C, to a mixture of **7** (0.093 g, 0.38 mmol) in MeCN and 2N HCl (1 mL: 0.2 mL, 5/1 v/v) was added N-chlorosuccinimide (0.201 g, 1.50 mmol) in portions. The mixture was stirred at $<$ 20 °C for 10 to 30 minutes. The solution was diluted with Et₂O and washed with 12% aqeuous NaCl (3x). The organic layer was dried (Na_2SO_4) and concentrated to give product as an off-white solid. The crude product was added $0.1N$ NaOH and dioxane (v/v 1/1). After 30 minutes, the mixture was concentrated and H_2O was added. The aqueous solution was washed with dichloromethane. After all, acidified it by concentrated HCl and lyophilized to get comp. **8**, then used it directly in next step. Compound **8** was refluxed in 6N HCl (3.8 mL) for 12 h. The H_2O was added (4mL), and then the aqueous solution was washed with dichloromethane (3x). The final solution was lyophilized to dry and used in next step.

The residue obtained above and NaOH (35 mg, 0.88 mmol) were dissolved in H₂O (3.5 mL) cooled in an ice bath. A solution of Fmoc-OSu (130 mg, 0.38 mmol) in dioxane (3.5 mL) was added in one portion. The mixture was stirred at room temperature (4 h), then the mixture was evaporated under reduced pressure and $H_2O(7.0$ mL) was added. The aqueous solution was washed with $Et₂O$ and acidified with concentrated aqueous HCl. The aqueous solution was lyophilized to yield crude product, which was purified by preparation HPLC (flow rate10 mL/minutes, acetonitrile/H₂O with 0.1% TFA, acetonitrile from 30% to 100% in 30 minutes; Retention time = 17.2 minutes) to provide pure **4c** as white foam 20 mg (14% for 4 steps). [α]_D¹⁸ 3.0 (c 0.95, MeOH); ¹H NMR (400 MHz, CD₃OD) δ 7.76 (d, *J* = 8.0 Hz, 2H), 7.66 (t, $J = 8.0$ Hz, 2H), 7.40 – 7.20 (m, 4H), 4.30 (d, $J = 4.0$ Hz, 2H), 4.20 (t, $J =$ 8.0 Hz, 2H), 3.02 (dd, $JI = 16.0$ Hz, $J/2 = 4.0$ Hz, 1H), 2.80 – 2.70 (m, 1H), 2.62 – 2.50 (m, 1H), 1.19 (d, $J = 8.0$ Hz, 3H); ¹³C NMR (100 MHz, CD₃OD) δ 173.6, 158.9, 145.4, 145.3, 142.7, 128.9, 128.3, 126.4, 121.0, 68.3, 60.5, 55.1, 34.3, 17.5; ESI-MS calcd for $C_{20}H_{22}NO_{7}S$ (M+H)⁺: 420.1, found: 420.0.

3.3. Synthesis of *N***-Fmoc (***2S,3S***)-2-aminuteso-5-(***tert***-butoxy)3-methyl-5-oxoentanoic acid (4d) from 9**

Conversion of the protected D-serine analogue **9** to **14** was according to literature procedures.⁵³

3.3.1. (*3S, 4S***)-Benzyl** *N, O***-isopropylidenyl-4-(***N***-***tert***-**

butyloxycarbonylamino)-3-methyl-5-oxo-pentanoate (15)—To a solution of **14** $(0.612 \text{ g}, 1.94 \text{ mmol})$ in THF-H₂O $(8 \text{ mL}/2 \text{ mL})$ at 0 °C was added LiOH•H₂O $(244 \text{ mg},$ 5.82 mmol) and the mixture was stirred at room temperature until the starting material was consumed (TLC). To the mixture was added 1N HCl until $pH = 2 - 3$, and then the THF was evaporated and the residue was extracted with EtOAc (3x). The combined organic phases were washed with brine, dried (MgSO4) and filtered and concentrated and the crude product was used directly in next step.

The crude material from above was dissolved in DMF (10 mL) at room temperature under argon and the NaHCO₃ (326 mg, 3.88 mmol) and BnBr $(0.346 \text{ mL}, 2.91 \text{ mmol})$ were added sequentially. The mixture was stirred until the starting material was consumed (TLC). The

mixture was diluted with EtOAc and then washed with H_2O , brine, dried (MgSO₄) and filtered and concentrated. The residue was purified by silica gel column chromatography (EtOAc: hexanes; from 1: 15 to 1: 4) to afford product **15** (0.5 g) as colorless oil (67% for two steps). [Note: Because it was found that starting **14** was obtained as ratio a 3:1 of diastereomers, which were difficult to separate, the diastereomeric mixture was used in the synthesis of **15**, resulting in a 3:1 diastereomeric product ration for **15**]: ¹H NMR (400 MHz, CDCl₃) δ 7.38 – 7.29 (m, 5H), 5.12 (s, 2H), 3.90 (d, $J = 8.0$ Hz, 2H), 3.79 (t, $J = 8.0$ Hz, 1H), $2.62 - 2.47$ (m, $2H$), $2.27 - 2.04$ (m, $1H$), $1.67 - 1.41$ (m, $15H$), 0.93 (d, $J = 8.0$ Hz, 3H); ESI-MS calcd for $C_{21}H_{32}NO_5 (M+H)^+$: 378.2, found: 378.2.

3.3.2. *N***-Fmoc (***2S,3S***)-2-Amino-5-(***tert***-butoxy)3-methyl-5-oxoentanoic acid**

(4d)—To a stirred solution of **15** (0.242 g, 0.64 mmol) in acetone (5.0 mL) at 0 °C was added freshly prepared Jones' reagent (2.7 M, 0.356 mL, 0.96 mmol). The mixture was allowed to warm to room temperature over 30 minutes, and then stirred at room temperature (1 h). Celite and isopropyl alcohol (1.48 mL) were added to the mixture and the resulting precipitate was removed by filtration and the filtrate was concentrated and extracted with EtOAc (3x). The combined extracts were washed with brine (2x), dried ($Na₂SO₄$) and concentrated in vacuo to give **16** (0.2 g) as colorless gum (89%).

Crude product **16** (0.16 g, 0.46 mmol) was dissolved in HCl in dioxone (4M, 1.1 mL, 4.55 mmol) and the reaction mixture was stirred at room temperature (3 h), then the solvent was removed by evaporation and the residue was dissolved in THF and H2O (4.5 mL: 4.5 mL, 1:1 v/v) and cooled in an ice bath. Sodium bicarbonate (69 mg, 0.82 mmol) and FmocOSu (0.23 g, 0.68 mmol) were added and the mixture was stirred at room temperature for (10 h). At this time, 1N HCl was added to adjust pH to 2–3, and then the THF was removed by evaporation. The resulting aqueous solution was extracted with EtOAc, and the combined organic extracts was washed with brine, dried $(Na₂SO₄)$, filtered and the filtrate concentrated under reduced pressure. The resulting crude product was purified by silica gel column chromatography (dichloromethane: MeOH, from 20: 1 to 10: 1) to yield **4d** (0.17 g) as a semisolid (81% for two steps). [As noted above, starting **15** was present as a diastereomeric mixture, **4d** was also obtained as a diastereomeric mixture]: 1H NMR (400 MHz, CDCl₃) δ 7.76 (d, J = 4.0 Hz, 2H), 7.59 (t, J = 4.0 Hz, 2H), 7.45 – 7.28 (m, 9H), 5.44 (d, $J = 8.0$ Hz, 1H), 5.15 (s, 2H), 4.62 (dd, $J = 8.0$ Hz, $D = 4.0$ Hz, 1H), 4.42 (d, $J = 8.0$ Hz, 2H), 4.22 (t, $J = 8.0$ Hz, 1H), $2.77 - 2.22$ (m, 3H), 0.96 (d, $J = 8.0$ Hz, 3H); ESI-MS calcd for $C_{28}H_{28}NO_6 (M+H)^{+}$: 474.2, found: 474.2.

3.4 Synthesis of *N***-Fmoc (***2S***)-2-amino-3-(benzyloxyphosphoryloxy)-3-methylbutanoic acid (4f) from 10**

Conversion of the protected D-serine analogue **10** to the Boc-protected amino acid **18** was according to literature procedures.⁵⁴

3.4.1. Allyl *N***-Fmoc (***2S***)-2-amino-3-hydroxyl-3-methylbutanoate (19)—**To a solution of **18** (0.503 g, 2.16 mmol) in DMF (10 mL) at room temperature under argon were sequentially added NaHCO₃ (0.362 g, 4.31 mmol) and allyl bromide (0.28 mL, 3.23 mmol) and the mixture was stirred until the starting material had been consumed (TLC). The mixture was diluted with EtOAc and the solution was washed with H_2O , brine and dried by (MgSO4) and then filtered and the filtrate concentrated. The resulting residue was purified by silica gel column chromatography (EtOAc: hexanes; from 1: 10 to 1: 2) to afford a white foam (0.35 g, 60%). This was dissolved in a 1M solution of HCl in Et₂O (12.44 mL, 12.44) mmol) and the reaction mixture stirred at room temperature (3 h). The solvent was then removed by evaporation and the residue was dissolved in a solution of THF: $H₂O$ (12 mL: 12 mL, 1:1 v/v) and cooled in an ice bath. Sodium bicarbonate (0.21 g, 2.49 mmol) and

FmocOSu (0.63 g, 1.87 mmol) were added and the mixture was stirred at room temperature (10 h). The THF was then removed by evaporation and the aqueous phase was extracted with EtOAc and the combined organic layer was washed with brine and dried (Na_2SO_4) , then filtered and concentrated under reduced pressure. The resulting residue was purified by silica gel column chromatography (EtOAc: hexanes; from 1: 10 to 1: 2) to yield product **19** (0.42 g) as a foam (85% for two steps). $[\alpha]_D^{18} - 17.0$ (c 1.3, CHCl3); ¹H NMR (400 MHz, CDCl₃) δ 7.78 (d, J = 4.0 Hz, 2H), 7.61 (d, J = 8.0 Hz, 2H), 7.41 (t, J = 8.0 Hz, 2H), 7.32 (t, $J = 8.0$ Hz, 2H), 6.0 – 5.86 (m, 1H), 5.72 (d, $J = 8.0$ Hz, 1H), 5.38 (d, $J = 16.0$ Hz, 1H), 5.29 $(d, J = 8.0 \text{ Hz}, 1\text{ H}), 4.76 - 4.62 \text{ (m, 2H)}, 4.50 - 4.37 \text{ (m, 2H)}, 4.32 \text{ (d, } J = 8.0 \text{ Hz}, 1\text{ H}), 4.24$ (t, $J = 8.0$ Hz, 1H), 2.55 (s, 1H), 1.31 (s, 3H), 1.29 (s, 3H); ¹³C NMR (100 MHz, CDCl₃) δ 171.6, 156.5, 144.0, 143.9, 141.5, 131.4, 127.9, 127.3, 125.3, 125.2, 120.21, 120.19, 119.7, 72.1, 67.4, 66.4, 61.8, 47.4, 27.2, 26.6; ESI-MS calcd for $C_{23}H_{26}NO_5 (M+H)^{+}$: 396.2, found: 396.1.

3.4.2. *N***-Fmoc (***2S***)-2-Amino-3-(dibenzyloxyphosphoryloxy)-3-methylbutanoic**

acid (20)—A solution of **19** (0.2 g, 0.51 mmol), dibenzyl-diisopropyl-phosphoramidite (0.35 g, 1.01 mmol) and N-methylaniline-trifluoroacetate (0.45 g, 2.02 mmol) in DMF (5 mL) were stirred at room temperature under argon (1 h). Oxidation was performed by addition of t-butyl-hydroperoxide in n-octane (5.0 M, 0.192 mL, 0.96 mmol). The solution was diluted with H_2O and extracted with EtOAc and the combined organic layer was washed with H_2O and brine, dried (MgSO₄), then filtered and the filtrate concentrated. The resulting residue was purified by silica gel column chromatography (EtOAc: hexanes; from 1:4 to 2:1) to provide **20** (0.3 g) as semisolid (90%). [α]_D¹⁸ −8.4 (c 0.7, CHCl₃); ¹H NMR $(400 \text{ MHz}, \text{CDCl}_3)$ δ 7.76 (d, J = 4.0 Hz, 2H), 7.65 – 7.60 (m, 2H), 7.43 – 7.28 (m, 14H), 6.40 (d, $J = 8.0$ Hz, 1H), $5.92 - 5.80$ (m, 1H), 5.31 (d, $J = 16.0$ Hz, 1H), 5.20 (d, $J = 12.0$ Hz, 1H), $5.10 - 4.96$ (m, $4H$), 4.62 (d, $J = 4.0$ Hz, $2H$), 4.43 (d, $J = 2.0$ Hz, $1H$), 4.40 (d, $J = 8.0$ Hz, 2H), 4.25 (t, $J = 8.0$ Hz, 1H), 1.65 (s, 3H), 1.60 (s, 3H); ¹³C NMR (100 MHz, CDCl₃) δ 169.2, 156.5, 144.1, 143.9, 141.5, 136.0, 131.6, 128.8, 128.7, 128.0, 127.9, 127.3, 125.4, 120.2, 119.3, 84.4, 69.5, 67.5, 66.4, 62.5, 47.4, 29.9, 26.5, 25.4; ESI-MS calcd for $C_{37}H_{38}NO_8P (M+H)^+$: 656.2, found: 656.2.

3.4.3. *N***-Fmoc (***2S***)-2-Amino-3-(benzyloxyphosphoryloxy)-3-methylbutanoic**

acid (4f)—To a solution of **20** (0.141 g, 0.22 mmol) in THF (1.1 mL) was added Nmethylaniline (70 μ L, 0.64 mmol) followed by the addition of Pd(PPh₃)₄ (0.012 g, 10.75 μmol). The mixture was protected from light and stirred under at room temperature under nitrogen (45 minutes). The mixture was then diluted with EtOAc and washed with saturated aqueous NH₄Cl. The NH₄Cl layer was back-extracted with EtOAc and the combined EtOAc extracts were dried (Na_2SO_4) filtered and concentrated. The resulting residue was purified by silica gel chromatography eluting first with dichloromethane:MeOH (50:1) to remove aniline impurities. Subsequent elution with dichloromethane:MeOH:AcOH(25:1:0.1) provided the free acid as foam (0.12 g, 91%). A portion of this material (0.06 g, 0.097 mmol) and 2,2′-dipyridyl (7.6 mg, 0.049 mmol) were dissolved in MeOH (1 mL) and 10% Pd/C (10 mg) was added and the flask was flushed with H_2 and subsequently stirred under a balloon of H_2 . After the reaction had achieved completion (TLC), the mixture was filtered and evaporated to dryness. The resulting oily solid was purified by preparative HPLC (flow rate 10 mL/minutes, acetonitrile/H2O with 0.1% TFA, acetonitrile from 30% to 100% in 20 minutes: retention time = 21.9 minutes) and lyophilized to provide **4f** as white foam 30 mg (60%). [α]_D¹⁸ –1.06 (c 0.45, CHCl3); ¹H NMR (400 MHz, CDCl₃) δ 9.85 (brs, 2H), 7.74 (d, $J = 8.0$ Hz, 2H), 7.59 (t, $J = 8.0$ Hz, 2H), 7.41 – 7.27 (m, 9H), 6.00 (brs, 1H), 5.05 (d, $J = 8.0$ Hz, 2H), $4.50 - 4.30$ (m, 3H), 4.20 (t, $J = 8.0$ Hz, 1H), 1.71 (s, 3H), 1.49 (s, 3H); 13C NMR (100 MHz, CDCl3) δ 173.6, 156.6, 144.0, 143.8, 141.5, 135.8, 128.8, 128.6,

128.0, 127.4, 125.4, 124.9, 120.2, 85.2, 69.6, 67.6, 62.8, 62.1, 47.3, 26.1, 25.5; ESI-MS calcd for $C_{27}H_{29}NO_8P (M+H)^+$: 526.2, found: 526.2.

3.5. Solid-Phase Peptide Synthesis

Fmoc protected amino acids **4a**, **4e**, **4g**, and other amino acids whose syntheses were not described above, were purchased from Novabiochem. Reagent **4b** was synthesized according to literature.⁵⁰ Reagent 3 was readily prepared as recently reported.⁵¹ Peptides were synthesized on NovaSyn®TGR resin (Novabiochem, cat. no. 01-64-0060) using standard Fmoc solid-phase protocols in N-Methyl-2-pyrrolidone (NMP). 1-O-Benzotriazole- N, N, N' , tetramethyl-uronium-hexafluoro-phosphate (HBTU) (5.0 eq.), hydroxybenzotriazole (HOBT) (5.0 eq.) and N,N-diisopropylethylaminutese (DIPEA) (10.0 eq.) were used as coupling reagents. Aminuteso terminal acetylation was achieved using 1 acetylimidazole. Finished resins were washed with DMF, MeOH, dichloromethane and $Et₂O$ and then dried under vacuum (overnight), washed with DMF, MeOH, dichloromethane and Et₂O and then dried under vacuum (overnight). Peptides were cleaved from the resin by treatment with TFA/H₂O/triisopropylsilane $(95/2.5/2.5)$ (4 h). The resins were then filtered and the filtrate was concentrated under vacuum, then precipitated with cold ether and the precipitate washed with cold ether. The resulting solid was dissolved in 50% aqueous acetonitrile 5 mL) and purified by reverse phase preparative HPLC using a Phenomenex C_{18} column (21 mm dia \times 250 mm, cat. no: 00G-4436-P0) with a linear gradient from 0% aqueous acetonitrile (0.1% trifluoroacetic acid) to 100% acetonitrile (0.1% trifluoroacetic acid) over 30 minutes at a flow rate of 10.0 mL/minute. Lyophilization gave product peptides as white powders. Peptides **2a – 2c** and **2e – 2k** were synthesized directly by standard Fmoc-based solid-phase protocols. Because peptide **2d** is obtained with the benzyl ester intact arising from amino acid **4d**, following HPLC purification the product was dissolved in MeOH and subjected to hydrogenolysis (10% $Pd \cdot C$, H₂) to afford the completely deprotected **2d**.

3.6 ELISA-based PBD-binding inhibition assays

Peptide pull-down assays were carried out essentially as described previously.38,42 A biotinylated p-T78 peptide was first diluted with 1X coating solution (KPL Inc., Gaithersburg, MD) to a final concentration of 0.3 μ M, and then 100 μ L of the resulting solution was immobilized onto a 96-well streptavidin-coated plate (Nalgene Nunc, Rochester, NY). The wells were washed once with PBS plus 0.05% Tween20 (PBST), and incubated with 200 μL of PBS plus 1% BSA (blocking buffer) for 1 h to prevent nonspecific binding. Mitotic 293A lysates expressing HA-EGFP-Plk1 were prepared in TBSN {20 mM Trish-Cl (pH 8.0), 150 mM NaCl, 0.5% NP-40, 5 mM EGTA, 1.5 mM EDTA, 20 mM p-nitrophenylphosphate and protease inhibitor cocktail (Roche) buffer $(\sim 60 \,\mu g)$ total lysates in 100 μL buffer), mixed with the indicated amount of peptide ligands and applied immediately onto the biotinylated p-T78 peptide-coated ELISA wells, and then incubated with constant rocking for 1 h at 25 °C. Following incubation, the ELISA plates were washed 4 times with PBST. To detect bound HA-EGFP-Plk1, the plates were probed for 2 h with 100 μL/well of anti-HA antibody at a concentration of 0.5 μg/mL in blocking buffer and then washed 5 times. The plates were further probed for 1 h with 100 μL/well of HRPconjugated secondary antibody (GE Healthcare, Piscataway, NJ) at a 1:1,000 dilution in blocking buffer. The plates were washed 5 times with PBST and incubated with $100 \mu L$ / well of 3,3['],5,5[']-tetramethylbenzidine (TMB) substrate solution (Sigma, St. Louis, MO) until a desired absorbance was achieved. The reactions were stopped by the addition of 100 μL/well of stop solution (Cell Signaling Technology, Danvers, MA) and the optical densities (O.D.) were measured at 450 nm using an ELISA plate reader (Molecular Devices, Sunnyvale, CA). Results are shown in Figures 3 and 4.

Acknowledgments

This work was supported in part by the Intramural Research Program of the NIH, Center for Cancer Research, NCI-Frederick and the National Cancer Institute, National Institutes of Health. We thank Drs. Christpher C. Lai and James A. Kelley of the CBL for obtaining the high-resolution mass spectra and for assistance in the interpretation of the data. Figure 1. Structures of peptides discussed in the text.

Figure 3.

ELISA-based Plk1 PBD-binding results. Representative graphs are shown from three independent experiments.

Figure 4.

ELISA-based Plk1 PBD-binding results. Representative graphs are shown from three independent experiments.

Scheme 1.

Reagents and conditions: a) AcSH (2.0 eq.), PPh₃ (2.0 eq.), DIAD (2.0 eq.), THF, 0° C – rt, 3 h, 98%; b) NaI (10.0 eq.), AcCl (10.0 eq.), MeCN, reflux, 7 h, 85%; c) 1) NCS (4.0 eq.), 2N HCl/MeCN (v/v, 1/4), 10 °C, 1 h; 2) 0.1N NaOH/dioxane (1: 1, v/v), rt, 0.5 h; d) 1) 6N HCl, reflux, 12 h; 2) FmocOSu, 0.1N NaOH/dioxane, overnight, 14% for four steps.

Scheme 2.

Reagents and conditions: a) 2,2-dimethoxypropane (10 eq.), BF₃ Et₂O (0.1eq.), acetone, rt, 2 h, 91%; b) 1) LiOH H2O (2.0 eq.), MeOH/H2O, rt, 4 h; 2) BOP (1.2 eq.), NH(OMe)Me HCl (1.25 eq.), Et3N (2.0 eq.), rt, 3 h, 70% for two steps; c) MeLi (1.7 eq.), THF, −78 °C, 1 h, 59%; d) triethyl phosphonoacetate (1.5 eq.), NaH (1.5 eq.), 0 °C, 24 h, 74%; e) 10% Pd•C, H2, MeOH/AcOEt, rt, 12 h, 97%; f) 1) LiOH H2O (3.0 eq.), THF/H2O, rt, 12 h.; 2) BnBr (1.5 eq.) , NaHCO₃ (2.0 eq.), DMF, rt, 24 h, 67% for two steps; g) 2.7 M Jones' reagent (1.5) eq.), acetone, rt, 30 min, 89%; h) 1) 4M HCl in dioxane (10 eq.), 3 h; 2) Fmoc-OSu(1.5 eq.), NaHCO₃ (2.0 eq.), THF – H₂O (v/v 1:1), 12 h, 81% for two steps.

Scheme 3.

Reagents and conditions: a) Mg (6.0 eq.), MeI (7.5 eq.), Et₂O, 0 °C, 30 min, 92%; b) Jones' reagent (2.7 M, 1.5 eq.), acetone, 0° C to rt, 1 h, 78%; c) 1) Allyl bromide (1.5 eq.), NaHCO₃ (2.0 eq.), DMF, rt, 24 h, 60%; 2) 1M HCl in Et₂O (10.0 eq.), rt, 3 h; 3) Fmoc-OSu (1.5 eq.), NaHCO₃ (2.0 eq.), THF/H₂O (1: 1 v/v), rt, 12 h, 85% for two steps; d) dibenzyl diisopropyl phosphoramidite (2.0 eq.), N-methylaniline trifluoroacetate (4.0 eq.), t-butyl hydroperoxide in *n*-octane (1.9 eq.), rt, 1 h, 90%; e) Pd(PPh₃)₄ (0.1 eq.), N-methylaniline (3.0 eq.), THF, rt, 1 h, 91%; 2) 10% Pd•C, 2, 2′-bipyridyl (0.5 eq.), H2, rt, 0.5 h, 60%.
