Abstract

The novel three-component domino reactions have been discovered. The reactions are easy to perform simply by mixing three common reactants in HOAc under microwave heating. The reaction proceeds at fast rates and can be finished within 20–36 min, which makes work-up convenient. Most of multiple stereocenters and geometry have been controlled well. The stereochemistry has been unequivocally determined by X-ray structural analysis.

Keywords

Three-component Domino Reaction; Nitrogen heterocycles; Pentcyclic Indeno[2; 1-*c*]quinoline; Pyrano[4; 3-*b*]oxepine; Stereochemistry

The search for efficient construction of multicyclic skeletons of chemically and biomedically importance has been an active theme in organic synthesis.^[1–3] Among these skeletons, the structurally diverse oxa-azaspiro skeletons commonly exist in nature and represented by daphnilactone A,^[1] serratezomine A^[2] and nitraramine (Figure 1),^[3] that exhibit a broad range of biological activities. These complex architectures have inspired the interest on creating strategies and tactics for total synthesis and methodologies.^[4–5]

In the past several years, multicomponent domino reactions (MDRs) and related environmentally benign, chemoselective and atom-efficient processes have emerged as powerful tools for the assembly of complex structures with multiple stereocenters in a onepot operation.^[6–10] These reactions can avoid time-consuming and costly purification of various precursors and tedious steps of protection/deprotection of functional groups.^[9] There have been several domino strategies for the diverse formation of oxa-azaspiro skeletons. However, the continuing search for more efficient MDRs for this synthesis still remains challenging, and continues to attract interest to synthetic community.

Recently, we and others have developed a series of MDRs that offer easy accesses to multiple functionalized ring structures of chemical and pharmaceutical interest.^[11–13] During our continuous study on MDR project,¹¹ we now discovered novel multicomponent annulations of enaminones with *o*-phthalaldehyde (OPA) and 4-hydroxy-6-methyl-2*H*-pyran-2-one divergently yielding multifunctionalized pyrano[3',2':2,3]indeno[2,1-*c*]quinolines **4** and ([3,4]furanoimino)benzo[e]pyrano[4,3-*b*]oxepines **5** (Scheme 1). The great aspects of these domino reactions are shown by the fact that up to five new bonds and three new rings (tricyclic 5-6-6 skeleton including cyclopentene, pyridine, and pyrane) were readily formed in domino fashions that involved [4+1]/[3+2+1]/[5+1] cyclizations; three stereocenters including a quaternary center and geometry were controlled well in a one-pot operation. The latter provided new bicyclic 7-7 skeleton including azepine and oxepine *via* double [4+3] cyclizations with high stereoselectivity. The present work represents the first example for constructing these special types of oxa-azaspiro **4** and oxa-azabridged **5** skeletons with multiple stereocenters.

The *o*-phthalaldehyde (OPA), possessing 1,4-biselectrophilic centers, has proven to be important building blocks for the construction of important cyclic skeletons.^[14] Our strategy of synthesizing highly functionalized pentacyclic lactams was started from the reaction of *o*-phthalaldehyde with 4-hydroxy-6-methyl-2H-pyran-2-one and enaminones based on the fact that two formyl groups would undergo double nucleophilic additions and subsequent double nucleophilic substitutions; and pyran-2-ones upon being treated with appropriate nucleophiles can be converted into new nucleophiles through ring cleavage (Scheme 2).

Based on the above analysis, the reaction of *o*-phthalaldehyde **1**, 4-hydroxy-6-methyl-2Hpyran-2-one **2** with 5,5-dimethyl-3-(4-chlorophenylamino)cyclohex-2-enone **3a** was first carried out in HOAc for 20 min at 80 °C under microwave irradiation condition (Scheme 3). Pleasantly, the white solid **4a** was obtained in 68% chemical yield. In contrast, other solvents, such as DMF, toluene, CHCl₃ and EtOH, led to poor results. Aprotic solvents (DMF, toluene and CHCl₃) resulted in less that 10% yield; protic solvent, EtOH, gave 12% isolated yield. Since metal triflates were known to show effective Lewis acidity even in the presence of water,^[15] three of them, Sc(OTf)₃, Cu(OTf)₂ and Fe(OTf)₂, were then empoyed attempting to enhance yield, but complex mixtures were formed, which made purification difficult.

With this acceptable condition in hand, we examined the scope of this synthesis by using various easily available starting materials. As revealed in Table 1, a range of polysubstituted pyrano[3',2':2,3]indeno[2,1-*c*]quinoline derivatives can be generated in moderate to good yields. The reaction is easy to perform simply by subjecting a mixture of *o*-phthalaldehyde 1, 4-hydroxy-6-methyl-2*H*-pyran-2-one 2, and enaminones 3 in acetic acids under microwave heating. We also examined the scope of enaminones and found several different *N*-substituents bearing electron-withdrawing or electron-donating groups were all suitable substrate. Although substrates **3k-3p** gave a mixture of two isomers (diastereoselectivity 64:36 to 89:11), most others (**3a-3j**) led to formation of single diastereoisomers. The structure of **4p** was unambiguously confirmed by X-ray crystal structural analysis (Fig. 2). Furthermore, halogen functional groups (Cl, Br and I) were tolerated well and would allow further functional group manipulations *via* cross-couplings.

In view of these results, we then turned our attention to investigate several differently substituted enaminones. The reactions of *o*-phthalaldehyde **1**, 4-hydroxy-6-methyl-2*H*-pyran-2-one **2** with *N*-substituted 4-aminofuran-2(5H)-ones (**3q**–**3w**) were performed under the above conditions for a short period (24–30 min). Surprisingly, the reaction occurred to another direction to form multi-functionalized pentcyclic pyrano[4,3-*b*]oxepines **5** (Scheme 4). This novel multicomponent domino reaction also exhibit a good scope of enaminone

substrates (Table 2) providing a straightforward pathway to construct highly substituted pentcyclic pyrano[4,3-*b*]oxepines. Similar to the former reaction, the latter also illustrates the remarkable chemo-, stereo-, and regioselectivity starting from very common and easily accessible inexpensive starting materials. The structural elucidation and the attribution of stereoselectivity were unequivocally determined by NMR spectroscopic analysis and X-ray diffraction of single crystals that were obtained by slow evaporation of the solvent, as in the case of product **5d** (Fig. 3). Both reactions occurred at a fast speed; in fact, all cases can be finished within 36 minutes. Water is nearly a sole by-product, which makes work-up convenient. In most cases, the products can precipitate out after cold water was poured into the reaction mixture. During these domino processes, up to three new rings and five sigmabonds were formed and accompanied by cleavage of two C=O of OPA and one C–O bonds of pyran-2-ones **2**, and all stereogenetic centers and geometry have been completely controlled including a quaternary center attached on the lactam ring. *It would be interesting to make collections of these natural product-like structures for screening*.

The mechanism hypothesis for these novel domino reactions are proposed and shown in Scheme 2. The former involves the ring closure cascade reactions that consist of initial condensation, Michael addition(\mathbf{A} to \mathbf{B}), intramolecular cyclization and ring-opening of pyran-2-ones **2** (\mathbf{B} to \mathbf{C}), and the second intramolecular cyclization (\mathbf{C} to **4**). The latter involves [4+3] cycloaddition to give azepinediols \mathbf{D} , which is followed by subsequent intermolecular double nucleophilic substitution (\mathbf{D} to **5**) leading to thermodynamically stable fused pyrano[4,3-b]oxepines **5**.

We reasoned that the divergence in these pathways could be caused by the different nucleophilicity of six-membered and five-membered N-substituted enaminones. With higher nucleophilicity, five-membered *N*-substituted enaminones favor double nucleophilic additions of two formyl groups on *o*-phthalaldehyde ring. This would resist *o*-phthalaldehyde to condensation with pyran-2-ones **2**.

In summary, we have successfully established the first domino [4+1]/[3+2+1]/[5+1] and double [4+3] cyclization reactions of *o*-phthalaldehyde, that led to the novel constructions of pentcyclic pyrano[3',2':2,3]indeno[2,1-c]pyridine and ([3,4]furanoimino) benzo[e]pyrano[4,3-b]oxepine skeletons with multiple stereocenters. The present work provides an attractive strategy for construction of structurally diverse pentcyclic oxa-azaspiro and oxa-azabridged skeletons. The ready accessibility of starting materials, the broad compatibility of *N*-substituted enaminones and generality of these reactions make them important in view of the synthetic and biomedical importance of fused heterocycles. Other features of this tactic include the mild condition, convenient one-pot operation, short periods of 20–36 min and excellent regioselectivity and good to high stereoselectivities. The continuing work on this project will be focused on the development of asymmetric versions of these reactions in due course.

Experimental Section

Example for the synthesis of 4a: 5-(4-Chlorophenyl)-3,3,9-trimethyl-3,4,10a,14b-tetrahydro-1H-pyrano[3',2':2,3]indeno[2,1-c]quinoline-1,6,7(2H,5H)-trione

o-Phthalaldehyde (1, 1.1 mmol, 1.1 equiv.) was introduced in a 10-mL vial, 4-hydroxy-6methyl-2H-pyran-2-one (2, 1.0 mmol, 1.0 equiv.) and 5,5-dimethyl-3-(4chlorophenylamino)cyclohex-2-enone (**3a**, 1.0 mmol, 1.0 equiv.) were then added, followed by HOAc (1.5 mL.). The reaction vial was capped and pre-stirring for 20 second. The mixture was irradiated at 80 °C until TLC monitoring (petroleum ether: acetone 3:1) showed that conversion of the starting material **3a** was complete (20 min). The reaction mixture was then cooled to room temperature and diluted with cold water (40 ml). The solid product was collected by Büchner filtration and was purified by flash column chromatography (silica gel, mixtures of petroleum ether/acetone, 7:1, v/v) to afford the desired pure products **4a** as white solid (Mp: 275–276 °C).

Example for the synthesis of 5a

o-Phthalaldehyde (1, 1.1 mmol) was introduced in a 10-mL vial, 4-hydroxy-6-methyl-2Hpyran-2-one (2, 1.0 mmol), and 4-((4-chlorophenyl)amino)furan-2(5H)-one (**3q**, 1.0 mmol) were added and followed by adding HOAc (1.5 mL). The reaction vial was capped and prestirring for 20 second. The mixture was irradiated at 80 °C until TLC monitoring (petroleum ether: acetone 2:1) showed that conversion of the starting material **3q** was complete (25 min). The reaction mixture was cooled to room temperature and diluted with cold water (50 ml). The solid product was collected by Büchner filtration and was purified by flash column chromatography (silica gel, mixtures of petroleum ether/acetone, 4:1, v/v) to afford the desired pure products **5a** as white solid (Mp: 247–248 °C).

Chemistry. Author manuscript; available in PMC 2013 August 06.

 $b_{\mathrm{Time \ (min)}}$

 $c_{\rm Isolated}$ yield.

 d The ratio of isomers was determined by ¹H NMR.

Table 2

Domino synthesis of pentcyclic pyrano[4,3-b]oxepines 5

Entry	5 ^a	R	Time/min	Yield ^b /%
1	5a	4-Chlorophenyl (3q)	25	81
2	5b	3-Fluorophenyl (3r)	24	72
3	5c	3-Bromophenyl (3s)	24	73
4	5d	Phenyl (3t)	28	79
5	5e	4-Methylpheny (3u)	30	84
6	5f	3-Methylpheny (3v)	30	71
7	5g	4-Methoxyphenyl (3w)	26	82

^aConditions: HOAc (1.5 mL), 80 °C, microwave heating.

b Isolated yield.
