Abstract

Anti-apoptotic members of the Bcl-2 family, including Bcl-2, Bcl-xL, Mcl-1, Bcl-w and Bfl-1, inhibit the mitochondrial pathway of apoptosis. Bcl-xL and Mcl-1 are constitutively expressed in the liver. Although previous research established Bcl-xL as a critical apoptosis antagonist in differentiated hepatocytes, the significance of Mcl-1 in the liver, especially in conjunction with Bcl-xL, has not been clear. To examine this question, we generated hepatocyte-specific Mcl-1–deficient mice by crossing *mcl-1*$^{flox/flox}$ mice and *AlbCre* mice and further crossed them with *bcl-x*$^{flox/flox}$ mice, giving Mcl-1/Bcl-xL– deficient mice. The *mcl-1*$^{flox/flox}$ *AlbCre* mice showed spontaneous apoptosis of hepatocytes after birth, as evidenced by elevated levels of serum alanine aminotransferase (ALT) and caspase-3/7 activity and an increased number of terminal deoxynucleotidyl transferase-mediated 2′-deoxyuridine 5′-triphosphate nick-end labeling (TUNEL)-positive cells in the liver; these phenotypes were very close to those previously found in hepatocyte-specific Bcl-xL– deficient mice. Although *mcl-1*$^{flox/+}$ *AlbCre* mice did not display apoptosis, their susceptibility to Fas-mediated liver injury significantly increased. Further crossing of Mcl-1 mice with Bcl-xL mice showed that *bcl-x*$^{flox/+}$ *mcl-1*$^{flox/+}$ *AlbCre* mice also showed spontaneous hepatocyte apoptosis similar to Bcl-xL– deficient or Mcl-1– deficient mice. In contrast, *bcl-x*$^{flox/flox}$ *mcl-1*$^{flox/+}$ *AlbCre*, *bcl-x*$^{flox/+}$ *mcl-1*$^{flox/flox}$ *AlbCre,* and *bcl-x*$^{flox/flox}$ *mcl-1*$^{flox/flox}$ *AlbCre* mice displayed a decreased number of hepatocytes and a reduced volume of the liver on day 18.5 of embryogenesis and rapidly died within 1 day after birth, developing hepatic failure evidenced by increased levels of blood ammonia and bilirubin. *Conclusion:* Mcl-1 is critical for blocking apoptosis in adult liver and, in the absence of Bcl-xL, is essential for normal liver development. Mcl-1 and Bcl-xL are two major anti-apoptotic Bcl-2 family proteins expressed in the liver and cooperatively control hepatic integrity during liver development and in adult liver homeostasis in a gene dose-dependent manner.

The mitochondrial pathway of apoptosis is regulated by the Bcl-2 family proteins.[1,2] They are functionally divided into two basic groups: pro-apoptotic and anti-apoptotic members. Pro-apoptotic members are further divided into multi-domain members, such as Bax and Bak, and BH3-only proteins. Bax/Bak triggers release from mitochondria of cytochrome c, presumably by forming pores at the mitochondrial outer membrane. Cytochrome c released into the cytosol activates multiple caspases, which cut a variety of cellular substrates and dismantle the cell.[3] The release of Bax/Bak–mediated cytochrome c is considered to be a point of no return and a commitment to cell death.[4] Killing by BH3-only proteins, such as Bid, Bim, or Puma, requires Bax or Bak, placing them upstream of Bak/Bax activation. BH3-only proteins are transcriptionally or posttranslationally activated by a variety of cellular stresses. They are considered to be sensors that transmit apoptotic stimuli to mitochondria. Anti-apoptotic members, including Bcl-2, Bcl-xL, Mcl-1, Bcl-w, and Bfl-1, inhibit the mitochondrial pathway of apoptosis either by directly blocking Bak/Bax activation or by sequestering BH3-only proteins from Bak or Bax.

Mcl-1 has increasingly attracted attention because of its role in liver disease. Several reports have shown that Mcl-1 is overexpressed in a subset of human hepatocellular carcinomas and provides apoptosis resistance.[5–7] The multi-kinase inhibitor sorafenib, which was recently approved by the Food and Drug Administration as a chemotherapeutic agent for hepatocellular carcinoma,[8] is capable of down-regulating Mcl-1 expression and producing apoptosis in hepatoma cells.[9] Cycloxygenase 2 or hepatocyte growth factor up-regulates Mcl-1 expression in hepatocytes and improves Fas-mediated liver injury.[10,11] Recently, enforced expression of Mcl-1 was reported to reduce liver injury induced by anti-Fas injection in mice.[12] However, little is known about the physiologic significance of Mcl-1 in hepatocytes.

We previously reported that hepatocyte-specific Bcl-xL knockout mice were born and grew up but developed spontaneous hepatocyte apoptosis, identifying Bcl-xL as a critical apoptosis antagonist in hepatocytes.[13] This raises a question of whether other anti-apoptotic Bcl-2 family members, such as Mcl-1, have a significant role in regulating hepatocyte apoptosis and what the relationship is among those molecules. To this end, in the current study, we generated hepatocyte-specific Mcl-1 knockout as well as Bcl-xL/Mcl-1 double knockout mice and found that, like Bcl-xL, Mcl-1 is critical for maintaining hepatocyte integrity in adult liver, but not essential for liver development. However, both deficiencies cause a severe defect in liver development and lethality during the early neonatal period because of severe hepatic failure. The current study identifies Bcl-xL and Mcl-1 as two major anti-apoptotic Bcl-2 family proteins in the liver and demonstrates their gene dose–dependent effects for controlling hepatic integrity.

Materials and Methods

Mice

Mice carrying the *mcl-1* gene encoding amino acids 1 through 179 flanked by 2 *lox*P (*mcl-1*$^{flox/flox}$) were provided by Dr. You-Wen He of Duke University.[14] Mice carrying a *bcl-x* gene with two *lox*P sequencers at the promoter region and a second intron (*bcl-x*$^{flox/flox}$) were described previously.[15] Heterozygous AlbCre transgenic mice expressing Cre recombinase gene under the promoter of the albumin gene were described previously.[13] We generated hepatocyte-specific Mcl-1 knockout mice (*mcl-1*$^{flox/floox}$ *AlbCre*) by mating *mcl-1*$^{flox/flox}$ and *AlbCre* mice. We then used these knockout mice to generate hepatocyte-specific Bcl-xL/Mcl-1 knockout mice (*bcl-x*$^{flox/flox}$ *mcl-1*$^{fl/oxflox}$ *AlbCre*) by mating them with *bcl-x*$^{flox/flox}$ mice. Traditional Bid knockout mice were described previously.[16] They were maintained in a specific pathogen–free facility and treated with humane care under approval from the Animal Care and Use Committee of Osaka University Medical School.

Genotyping

Genomic DNA was extracted from the tail and subjected for polymerase chain reaction (PCR) for genotyping mice. The primers used were as follows: 5′-GCCACCTCATCAGTCGGG-3′ and 5′-TCAGAAGCCGCAATATCCCC-3′ for the *bcl-x* allele; 5′-GGTTCCCTGTCTCCTTACTTACTGTAG-3′ and 5′-CTCCTAACCACTGTTCCTGACATCC-3′ for the *mcl-1* allele; 5′-GCGGTCTGGCAGTAAAAACTATC-3′, 5′-GTGAAACAGCATTGCTGTCACTT-3′, 5′CTAGGCCACAGAATTGAAAGATCT-3′ 5′-GTAGGTGGAAATTCTAGCATCATCC-3′ for the *AlbCre* allele; 5′-CCGAAA TGTCCCATAAGAG-3′, 5′-GAGATGGACCACAACATC-3′, and 5′ TGCTACTTCCATTTGTCACGTCCT-3′ for the *bid* allele. PCR products were electrophoretically separated using 2% agarose gels. The expected sizes of the PCR products were as follows: 165 bp for the wild-type *bcl-x* allele, 195 bp for the floxed *bcl-x* allele, 200 bp for the wild-type *mcl-1* allele, 300 bp for the floxed *mcl-1* allele, 130 bp for the wild-type *bid* allele, and 350 bp for the *bid* knockout allele. *AlbCre*-negative mice showed a 350-bp band, and heterozygous *AlbCre* mice showed 100-bp and 350-bp double bands.

Apoptosis Assay

To measure serum ALT level and caspase-3/7 activity, blood was collected from the inferior vena cava of mice and centrifuged. Serum was stored at −20°C until use. Serum ALT levels were measured by a standard method at Oriental Kobo Life Science Laboratory (Nagahama, Japan), and serum caspase-3/7 activity was measured by a luminescent substrate assay for caspase-3 and caspase-7 (Caspase-Glo assay, Promega, Tokyo, Japan). For histological analysis, livers were formalin-fixed, embedded in paraffin, and thin sliced. The liver sections were stained with hematoxylineosin. To detect cells with oligonucleosomal DNA breaks, the sections were also subjected to terminal deoxynucleotidyl transferase-mediated 2′-deoxyuridine 5′-triphosphate nick-end labeling (TUNEL) staining, according to a previously reported procedure.[17] For Fas-stimulating study, anti-Fas antibody (Jo2 clone) (PharMingen, San Diego, CA) was intraperitoneally injected into mice 3 hours before sacrifice.

Western Blot Analysis

Approximately 25 mg liver tissues was lysed with a lysis buffer (1% NP-40, 0.5% sodium deoxycholate, 0.1% sodium dodecyl sulfate and 1× protein inhibitor cocktail (Nacalai tesque, Kyoto, Japan), phosphate-buffered saline; pH 7.4). After incubation on ice for 15 minutes, the lysate was centrifuged at 10,000*g* for 15 minutes at 4°C. The protein content of the supernatants was determined using a bicinchoninic acid protein assay kit (Pierce, Rockford, IL). Equal amounts of protein were electrophoretically separated by sodium dodecyl sulfate polyacrylamide gels (8% or 12%) and transferred onto polyvinylidene fluoride membrane. For immunodetection, the following antibodies were used: anti–Bcl-xL antibody (Santa Cruz Biotechnology, Santa Cruz, CA), anti–Mcl-1 antibody (Rockland, Gilbertsville, PA), anti-Bax antibody (Cell Signaling Technology, Beverly, MA), anti-Bid antibody (Cell Signaling Technology), anti-albumin antibody (Affinity Bioreagents, Golden, CO), and anti– beta actin antibody (Sigma-Aldrich, Saint Louis, MO). Detection of immunolabeled proteins was performed using a chemiluminescent substrate (Pierce).

Neonate Analysis

Neonatal mice delivered by cesarean section were suckled by a surrogate mother and sacrificed at 10 hours after birth. Blood from the neonatal mice was centrifuged, and the plasma was stored at −20°C until use. The levels of total bilirubin and ammonia were

measured by Van den Bergh reaction and a standard enzymatic procedure, respectively, at Oriental Kobo Life Science Laboratory.

Real-Time Reverse-Transcription PCR

Total RNA was prepared from liver tissue using RNeasy kit (QIA-GEN, Tokyo, Japan). For complementary DNA synthesis, 1 μg total RNA was reverse-transcribed using the High Capacity RNA-to-DNA Master Mix (Applied Biosystems, Foster City, CA). Complementary DNA, equivalent to 40 ng RNA, was used as a template for real-time reverse-transcription PCR (RT-PCR) using an Applied Biosystems 7900HT Fast Real-Time PCR System (Applied Biosystems). The messenger RNA expressions of tumor necrosis factor alpha (TNF-α), collagen-alpha1(I), and transthyretin were measured using TaqMan Gene Expression Assays (Assay ID: Mm00443260_g1, Mm00801666_g1, and Mm00443267_m1, respectively), and were corrected with the quantified expression level of beta-actin messenger RNA measured using TaqMan Gene Expression Assays (Assay ID: Mm02619580_g1).

Statistical Analysis

Data are presented as mean ± standard deviation. Comparisons between two groups were performed by unpaired *t* test. Multiple comparisons were performed by analysis of variance followed by Scheffe *post hoc* correction. $P < 0.05$ was considered statistically significant.

Results

Hepatocyte-Specific Mcl-1 Deficiency Leads to Spontaneous Hepatocyte Apoptosis in the Adult Liver

To generate hepatocyte-specific Mcl-1– deficient mice, floxed *mcl-1* mice were crossed with heterozygous *AlbCre* mice. After *mcl-1*$^{flox/+}$ *AlbCre* mice were mated with *mcl-1*$^{flox/+}$ mice, and offspring were screened for genotyping and Mcl-1 expression. *mcl-1*$^{flox/flox}$ *AlbCre* mice were born and grew up. Their expression in the liver of Mcl-1 was greatly reduced compared with that of wild-type mice (Fig. 1A). The levels of Bcl-xL expression did not change in *mcl-1*$^{flox/flox}$ *AlbCre* liver. Bcl-xL and Mcl-1 proteins migrated as typical doublet bands of which the biochemical nature had been previously determined.[18] The trace amount of Mcl-1 expression found in the knockout liver may have been attributable to expression in nonparenchymal cells, as previously observed in hepatocyte-specific Bcl-xL–deficient mice.[13]

To investigate the significance of Mcl-1 in the liver, mice were sacrificed 6 weeks after birth and subjected to analysis of serum ALT levels and caspase-3/7 activity as well as liver histology and TUNEL staining. *mcl-1*$^{flox/flox}$ *AlbCre* mice displayed significantly higher levels of serum ALT than control mice (*AlbCre*-negative or *mcl-1*$^{+/+}$ *Al-bCre* mice) (Fig. 1B). Hepatocytes with typical apoptosis morphology such as cellular shrinkage and nuclear condensation were frequently observed in the liver sections of *mcl-1*$^{flox/flox}$ *AlbCre* mice (Fig. 1C). Consistently, the number of cells with TUNEL positivity, a hallmark of apoptotic cell death, in the liver was significantly higher in *mcl-1*$^{flox/flox}$ *AlbCre* mice than in control mice (Fig. 1C). Activity of caspase-3/7, executioners of apoptosis, was significantly higher in circulation of *mcl-1*$^{flox/flox}$ *AlbCre* mice than in control mice, which might reflect activation of those proteases in the knockout liver (Fig. 1D). Bax expression was clearly increased in *mcl-1*$^{flox/flox}$ *AlbCre* mice, suggesting Bax activation being involved in the apoptosis in *mcl-1*$^{flox/flox}$ *AlbCre* mice (Fig. 1A). Furthermore, the expression of TNF-α and collagen-alpha1(I) was significantly increased in the *mcl-1*$^{flox/flox}$ *AlbCre* liver compared with the wild-type liver, as found in the Bcl-xL knockout liver (Fig. 1E). Taken together, hepatocyte-specific Mcl-1 knockout mice developed spontaneous apoptosis leading

to sterile inflammation and fibrotic response in the liver, like hepatocyte-specific Bcl-xL knockout mice.[13]

Heterozygous Deletion of the mcl-1 Gene Does Not Produce Apoptosis But Increases the Susceptibility to Fas Stimulation

Although the levels of Mcl-1 expression were significantly decreased in *mcl-1$^{flox/+}$ AlbCre* liver (Fig. 1A, Supporting Fig. 1), *mcl-1$^{flox/+}$ AlbCre* mice did not have apoptosis phenotypes in the liver (Fig. 1B–D). Therefore, we examined the susceptibility to Fas stimulation in these mice. We injected anti-Fas antibody into *mcl-1$^{flox/+}$ AlbCre* mice and *mcl-1$^{flox/+\ or\ flox}$* mice and measured the levels of their serum ALT. *mcl-1$^{flox/+}$ AlbCre* mice displayed significantly higher levels of serum ALT than control mice (Fig. 1F). These findings suggest that haplo-deficiency of Mcl-1 does not produce apoptosis in a physiological setting but clearly reduces apoptosis resistance under pathological conditions.

Involvement of Bid in Apoptosis Caused by Mcl-1 Deficiency

BH3-only proteins regulate life and death balance by interacting with core Bcl-2 family members. The hepatocyte is a so-called type 2 cell, which requires Bid as a sensor for Fas-mediated apoptotic stresses.[19] In addition, it has been reported that the caspase-8/Bid pathway is involved in a variety of liver pathological conditions.[16,20] To examine the possibility of Bid being involved in hepatocyte apoptosis caused by Mcl-1 deficiency, we crossed hepatocyte-specific Mcl-1 knockout mice with Bid knockout mice. Offspring form mating of *bid$^{+/-}$ mcl-1$^{flox/flox}$ AlbCre* mice with *bid$^{+/-}$ mcl-1$^{flox/flox}$* mice were sacrificed at 6 weeks after birth and subjected to analysis of apoptosis phenotypes. Mice with each genotype grew up, and, as expected, the levels of Bid and/or Mcl-1 expression in the liver were correspondingly reduced with their genotypes (Fig. 2A). The levels of serum ALT were significantly lower in *bid$^{+/-}$ mcl-1$^{flox/flox}$ AlbCre* mice than in *bid$^{+/+}$ mcl-1$^{flox/flox}$ AlbCre* mice (Fig. 2B). The results indicate that Bid was involved in hepatocyte apoptosis found in Mcl-1 knockout mice.

Combined Deficiency of Mcl-1 and Bcl-xL in Hepatocytes Causes Lethality

Phenotypes observed in hepatocyte-specific Mcl-1 knockout mice were very similar to those in hepatocyte-specific Bcl-xL knockout mice.[13] These results indicated that Bcl-xL and Mcl-1 share similar anti-apoptotic functions but do not compensate for the loss of each other. To examine whether their expression and function are completely nonredundant or just partially so, we generated hepatocyte-specific Bcl-xL/Mcl-1 double-knockout mice.

The *bcl-x$^{flox/+}$ mcl-1$^{flox/+}$ AlbCre* mice were mated with *bcl-x$^{flox/flox}$ mcl-1$^{flox/flox}$* mice, and genotypes of the offspring were screened at 3 weeks after birth. *AlbCre*-negative and *bcl-x$^{flox/+}$ mcl-1$^{flox/+}$ AlbCre* mice were born and grew up, but not *bcl-x$^{flox/flox}$ mcl-1$^{flox/+}$ AlbCre*, *bcl-x$^{flox/+}$ mcl-1$^{flox/flox}$ AlbCre,* and *bcl-x$^{flox/flox}$ mcl-1$^{flox/flox}$ AlbCre* mice (Table 1). The lack of Bcl-xL and Mcl-1 caused a more severe phenotype than either knockout, suggesting that they partially compensate for the loss of each other at least from the viewpoint of maintaining normal development.

Mice Lacking Single Alleles for Both Bcl-xL and Mcl-1 Develop Spontaneous Apoptosis in the Adult Liver Similar to Bcl-xL or Mcl-1 Knockout Mice

Offspring from mating of *bcl-x$^{flox/+}$ mcl-1$^{flox/+}$ AlbCre and bcl-x$^{flox/flox}$ mcl-1$^{flox/flox}$* were sacrificed at 6 weeks after birth and subjected to analysis of Bcl-xL/Mcl-1 expression and apoptosis phenotypes. As expected, *bcl-x$^{flox/+}$ mcl-1$^{flox/+}$ AlbCre* liver expressed reduced levels of expression for both Bcl-xL and Mcl-1 (Fig. 3A). Interestingly, *bcl-x$^{flox/+}$ mcl-1$^{flox/+}$ AlbCre* mice developed spontaneous hepatocyte apoptosis as evidenced by an

increase in serum ALT levels and caspase-3/7 activity (Fig. 3B,C). In agreement with this, hepatocytes with typical apoptotic morphology and positive for TUNEL staining were found scattered in the liver lobules in these mice (Fig. 3D,E). Furthermore, *bcl-x*$^{flox/+}$ *mcl-1*$^{flox/+}$ *AlbCre* mice showed higher expression of TNF-α than wild-type mice (Fig. 3F). The phenotypes were very similar to hepatocyte-specific Bcl-xL or Mcl-1knockout mice.

Hepatocyte-Specific Mcl-1/Bcl-xL-Deficient Mice Show Impaired Development of the Liver and Liver Failure During the Neonatal Period

To examine the impact of Bcl-xL/Mcl-1deficiency at an earlier time point, offspring obtained from crossing *bcl-x*$^{flox/+}$ *mcl-1*$^{flox/+}$ *AlbCre* mice and *bcl-x*$^{flox/flox}$ *mcl-1*$^{flox/flox}$ mice were analyzed on gestational day 18.5. Live-obtained embryo followed expected Mendelian frequencies (Table 1). Overall, they looked normal, and their body weight did not differ among genotypes (Fig. 4A,B). However, the livers obtained from live pups with genotype of *bcl-x*$^{flox/flox}$ *mcl-1*$^{flox/+}$ *AlbCre*, *bcl-x*$^{flox/+}$ *mcl-1*$^{flox/flox}$ *Alb-Cre,* or *bcl-x*$^{flox/flox}$ *mcl-1*$^{flox/flox}$ *AlbCre* were clearly smaller. The ratios of liver weight to body weight were significantly lower in those pups than in *AlbCre*-negative or *bcl-x*$^{flox/+}$ *mcl-1*$^{flox/+}$ *AlbCre* pups (Fig. 4C). The ratios of liver weight to body weight were also examined in *mcl-1*$^{flox/flox}$ with *AlbCre* or without *AlbCre* mice, and there was no significant difference between the two (6.0 ± 0.8 versus 5.5 ± 0.9, N = 5, $P = 0.34$), excluding the possibility that Mcl-1 knockout itself affects the liver size at this time point. Histological analysis revealed that there were a number of hepatocytes with rectangular morphology and hematopoietic cells in the developing liver of the *AlbCre*-negative pups (Fig. 4D). Whereas the number of rectangular hepatocytes in *bcl-x*$^{flox/+}$ *mcl-1*$^{flox/+}$ *AlbCre* livers was similar to that in the *AlbCre*-negative livers, it was lower in *bcl-x*$^{flox/flox}$ *mcl-1*$^{flox/+}$ *AlbCre*, *bcl-x*$^{flox/+}$ *mcl-1*$^{flox/flox}$ *AlbCre,* and *bcl-x*$^{flox/flox}$ *mcl-1*$^{flox/flox}$ *AlbCre* livers. Rectangular cells were rarely observed in *bcl-x*$^{flox/flox}$ *mcl-1*$^{flox/flox}$ *Alb-Cre* livers. Furthermore, the expression of albumin and transthyretin was examined in the liver as a marker for hepatocyte differentiation.[21] Consistent with histological findings, both expressions were gradually reduced from the *AlbCre*-negative livers to the *bcl-x*$^{flox/flox}$ *mcl-1*$^{flox/flox}$ *AlbCre* livers (Fig. 4E,F).

We noticed that offspring obtained from crossing *bcl-x*$^{flox/+}$ *mcl-1*$^{flox/+}$ *AlbCre* mice and *bcl-x*$^{flox/flox}$ *mcl-1*$^{flox/flox}$ mice frequently died within 1 day after birth. To examine the cause of the early neonatal death, offspring were sacrificed at 10 hours after birth. They were divided into two groups according to the data shown in Table 1: expected survivors including *AlbCre*-negative and *bcl-x*$^{flox/+}$ *mcl-1*$^{flox/+}$ *AlbCre* pups, and expected nonsurvivors including *bcl-x*$^{flox/flox}$ *mcl-1*$^{flox/+}$ *AlbCre*, *bcl-x*$^{flox/+}$ *mcl-1*$^{flox/flox}$ *AlbCre*, and *bcl-x*$^{flox/flox}$ *mcl-1*$^{flox/flox}$ *AlbCre* pups. The levels of total bilirubin and ammonia in circulation were determined and compared between the groups. Both blood bilirubin levels and ammonia levels were significantly higher in the expected nonsurvivors than in the expected survivors (Fig. 5A,B). These results suggested that *bcl-x*$^{flox/flox}$ *mcl-1*$^{flox/+}$ *AlbCre*, *bcl-x*$^{flox/+}$ *mcl-1*$^{flox/flox}$ *AlbCre*, and *bcl-x*$^{flox/flox}$ *mcl-1*$^{flox/flox}$ *AlbCre* mice died quickly after birth because of hepatic failure, in agreement with the findings of impaired liver development.

Discussion

Five members of the anti-apoptotic Bcl-2 family have been found: Bcl-2, Bcl-xL, Bcl-w, Bfl-1, and Mcl-1. Traditional knockout of Bcl-2, a prototype of this family, displays growth retardation, hair color abnormality, lymphocyte decrease, and polycystic kidney.[22,23] In agreement with the finding that Bcl-2 is not expressed in hepatocytes,[13] these mice did not show any liver phenotypes. Similarly, Bcl-w[24,25] or Bfl-1 knockout mice[26] were generated but no liver phenotypes have been reported. Traditional knockout of Bcl-xL or Mcl-1 caused

more severe phenotypes. Deletion of the *bcl-x* gene resulted in embryonic lethality because of abnormal neuronal development and hematopoiesis.[27] The *mcl-1* knockout embryo fails to be implanted *in utero*.[28] Thus, study of traditional knock-out mice could not reveal the significance of Bcl-xL or Mcl-1 in the liver.

We previously reported that hepatocyte-specific knockout of Bcl-xL caused spontaneous apoptosis in hepatocytes after birth and established that Bcl-xL is critically important for the integrity of hepatocytes.[13] The current study demonstrated that Mcl-1 plays an anti-apoptotic role in differentiated hepatocytes similar to that of Bcl-xL. During the preparation of this manuscript, a report by Vick et al.[29] appeared on the Web, demonstrating a similar apoptosis phenotype in mice with specific knockout of the *mcl-1* gene in hepatocytes. Our findings are in agreement with theirs and further provide evidence that deletion of a single allele for the *mcl-1* gene fails to produce apoptosis phenotypes under physiological conditions, as observed in knockout of the *bcl-x* gene.[13] Mcl-1 heterozygous disrupted mice did not produce apoptosis at least until 16 weeks of age (our unpublished data). It was demonstrated that hepatocyte-specific Mcl-1 knockout mice showed higher levels of liver injury than control mice on anti-Fas antibody injection.[29] However, because mice lacking both *mcl-1* alleles possess preexisting liver injury, it would be difficult to exactly compare liver injury after anti-Fas antibody injection and to conclude whether decreased Mcl-1 expression actually increases the susceptibility to Fas. In the current study, we took advantage of Mcl-1 heterozygous disrupted mice to address this point. They showed significantly higher levels of liver injury after Fas stimulation than wild-type mice, formally proving the significance of Mcl-1 expression under pathological conditions. Furthermore, our data on Mcl-1/Bid– deficient mice implies that the Bid pathway is involved in generating apoptosis found in Mcl-1 knockout mice. Because Bid mediates a variety of cellular stresses in hepatocytes upstream of Mcl-1,[30,31] it will be interesting in future study to determine what stresses generate hepatocyte apoptosis in Mcl-1 knockout mice.

Bcl-xL and Mcl-1 share similar structures and functions.[1] The observations that either deficiency similarly leads to spontaneous hepatocyte apoptosis imply that they play a non-redundant role in maintaining the integrity of hepatocytes in the adult liver. To further understand the relationship of both molecules, we generated hepatocyte-specific Bcl-xL/Mcl-1 knockout mice. Interestingly, mice lacking single alleles for both genes ($bcl\text{-}x^{+/-}$ $mcl\text{-}1^{+/-}$) induced spontaneous hepatocyte apoptosis that could not be distinguished from that found in Bcl-xL or Mcl-1 knockout mice. This indicates that, whereas knockout of a single allele of the *bcl-x* or *mcl*-1 gene did not produce apoptosis, knockout of two alleles of any combination among both genes was sufficient to produce hepatocyte apoptosis. This finding suggests that both molecules are not independently but rather interdependently required for ensuring integrity of differentiated hepatocytes.

Bcl-xL/Mcl-1-deficient mice as well as mice only having a single allele of either *bcl-x* or *mcl-1* gene displayed a decreased number of hepatocytes and reduced liver size on day 18.5 of gestation and appeared to develop lethal liver failure within 1 day after birth. Because the liver contains a large number of hematopoietic cells during development (Fig. 4D), it is very difficult to determine the expression levels of Bcl-xL or Mcl-1 specifically in hepatocytes in each knockout mouse. Liver development begins on day 8.5 of gestation in the mouse when the liver primordium is delineated from the endoderm.[32] The albumin promoter, which is active in both hepatoblasts and hepatocytes, shows a 20-fold increase in transcriptional activity from day 9.5 to day 12.5 of gestation. The level of albumin then continues to increase as the liver develops simultaneously with the biliary tree and the hepatic bile duct being formed.[33] Thus, the target genes could probably be successfully deleted during embryogenesis in the *AlbCre* recombination system. The observation that Bcl-xL/Mcl-1–deficient mice developed severer phenotypes than Bcl-xL– deficient or Mcl-1– deficient

mice supports the idea that Cre-mediated deletion of the target genes actually took place during embryogenesis in our model. In contrast to the knockout of two alleles, knockout of three alleles and more of the *bcl-x* and *mcl-1* genes induced lethal neonatal hepatic failure. Thus, hepatocyte integrity appeared to be strictly controlled by Bcl-xL and Mcl-1 in a gene dose– dependent manner.

Hepatocyte-specific deficiency of both Bcl-xL and Mcl-1 led to significant reduction of liver volume because of impaired hepatocyte development. However, overall, mice with these phenotypes were capable of developing normally until birth and rapidly developed liver failure and died within 1 day after birth. This finding suggests that differentiated hepatocytes are critically required for maintaining host homeostasis after birth but not during embryogenesis. The placenta plays an important role in nutritional support and de-toxification of the embryo. Our data imply that it could probably compensate for most functions of the liver cells during embryogenesis, whereas the liver would turn to the critical organ that is essential for maintaining host homeostasis after birth. Bcl-xL/Mcl-1 knockout mice provide interesting implications for the difference in the impact of differentiated hepatocytes between embryogenesis and the early neonatal period.

In conclusion, Mcl-1 and Bcl-xL are two major Bcl-2 family proteins inhibiting hepatocyte apoptosis. Together with previous work on traditional knockout mice, our data imply that other members, if any, could not compensate for their functions. Mcl-1 and Bcl-xL cooperatively maintain hepatocyte integrity during liver development and in adult liver homeostasis, and their effects are gene-dose dependent. Recent studies also have established that Mcl-1[5–7] and Bcl-xL[18,34] are frequently overexpressed and confer resistance to apoptosis in hepatocellular carcinoma. Therefore, Mcl-1 and Bcl-xL are important apoptosis antagonists in a variety of pathophysiological conditions of the liver.

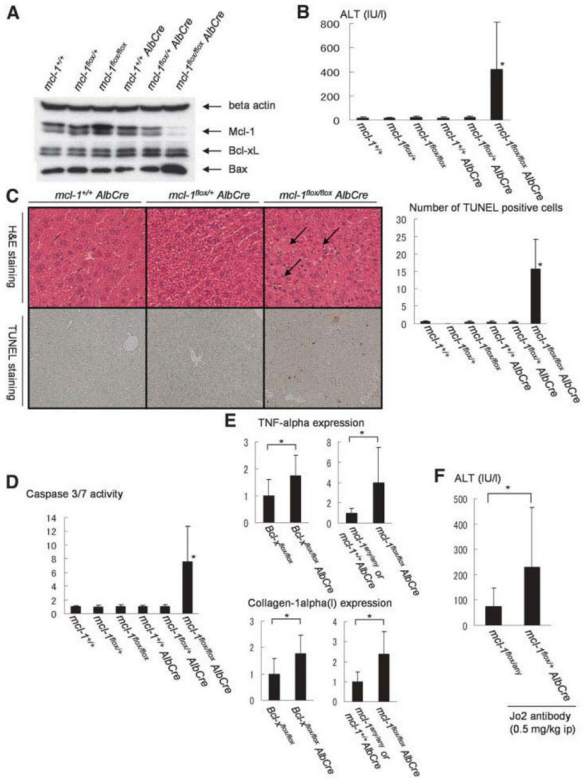

Fig. 1.

Hepatocyte-specific Mcl-1 knockout mice. Offspring from mating of *mcl-1*$^{flox/+}$ *AlbCre* mice and *mcl-1*$^{flox/+}$ mice were sacrificed at the age of 6 weeks. (A) Western blot of whole liver lysate for the expression of Bcl-xL, Mcl-1, and Bax. (B) Serum ALT levels. N = 15 mice for each group. *$P < 0.05$ versus the other five groups. (C) Left panel shows hematoxylin-eosin and TUNEL staining of the liver section. Arrow indicates typical apoptotic cells. Right panel shows statistics of TUNEL-positive cells. The number of TUNEL-positive cells was determined in a defined area. N = 5 mice for each group. *$P <$ 0.05 versus the other five groups. (D) Serum levels of caspase-3/7 activity. The levels were normalized to *mcl-1*$^{+/+}$ *AlbCre (−)* mice. N = 15 mice for each group. *P < 0.05 versus the other five groups. (E) Real-time RT-PCR analysis for TNF-α and collagen-1alpha(1) expression. *$P < 0.05$. N = 12 or 9. The levels were normalized to the wild-type mice. (F) Serum ALT levels of Fas-stimulated mice. The *mcl-1*$^{flox/+}$ *AlbCre* mice and *mcl-1*$^{flox/+ \text{ or } flox}$ mice were sacrificed 3 hours after intraperitoneal injection of 0.5 mg/kg Jo2 antibody. *$P < 0.05$. N = 13 or 7.

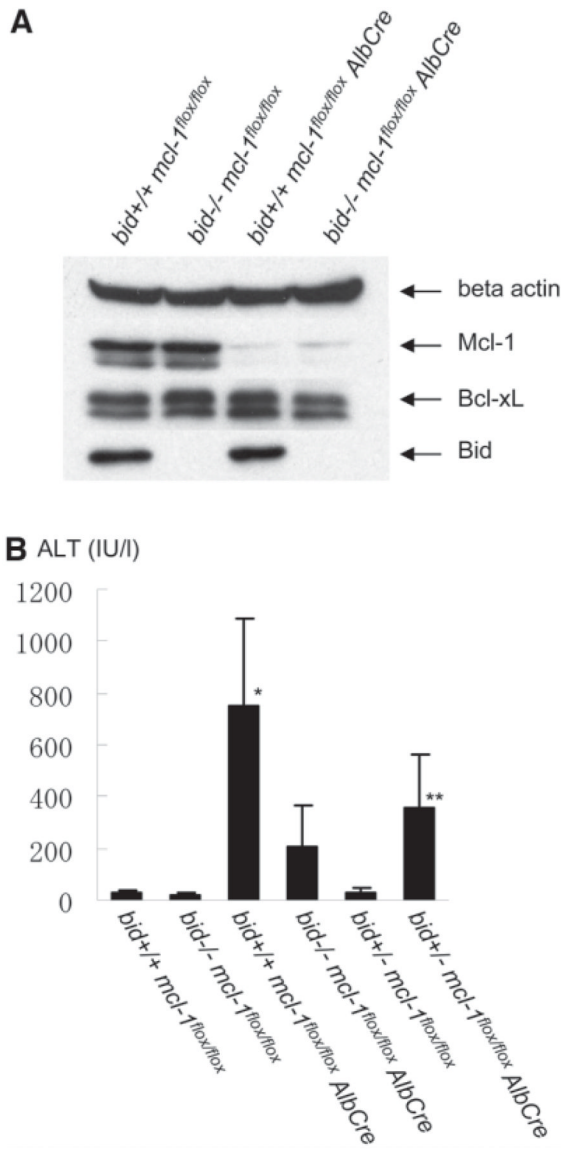

Fig. 2.

Mcl-1/Bid double-knockout mice. Offspring from mating of *bid*$^{+/-}$ *mcl-1*$^{flox/flox}$ *AlbCre* mice with *bid*$^{+/-}$ *mcl-1*$^{flox/flox}$ mice were sacrificed at 6 weeks after birth. (A) Western blot of whole liver lysate for the expression of Mcl-1, Bcl-xL, and Bid. (B) Serum ALT levels. N = 12 mice for each group. *$P < 0.05$ versus the other five groups; **$P < 0.05$ versus the *AlbCre*-negative groups and the *bid*$^{+/+}$ *mcl-1*$^{flox/flox}$ *AlbCre* group.

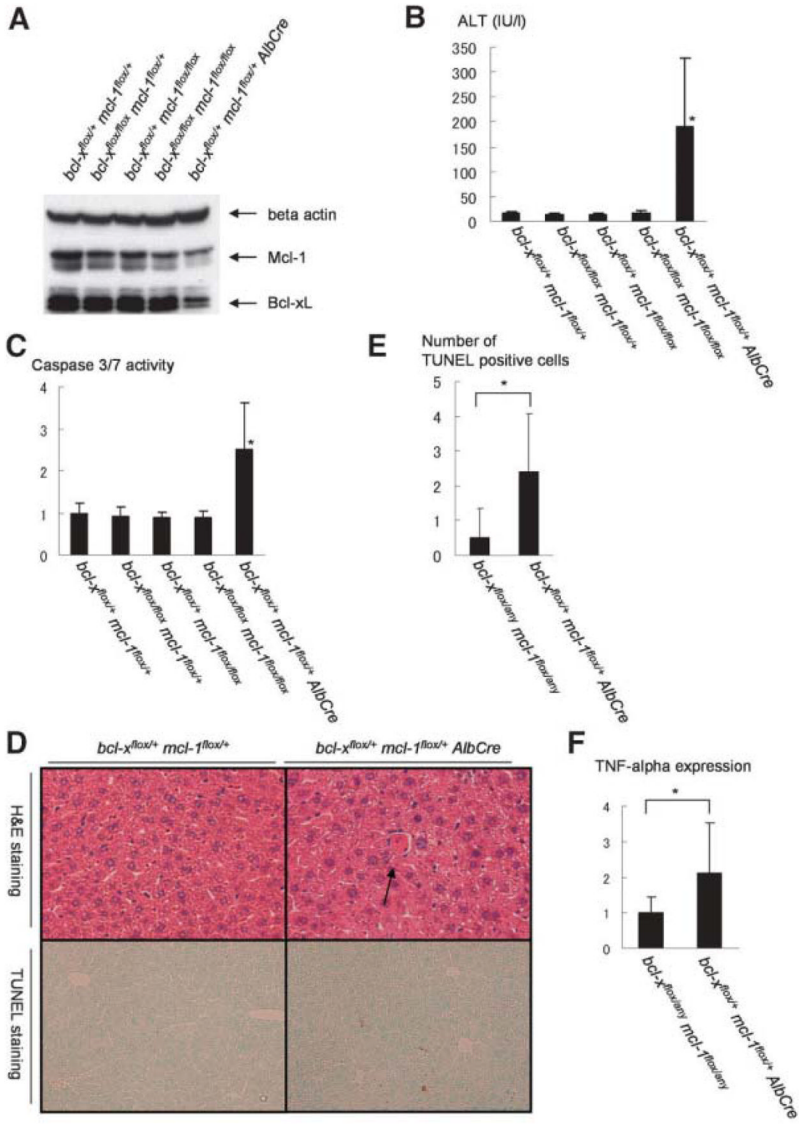

Fig. 3.

Hepatocyte-specific Bcl-xL/Mcl-1– deficient mice. Offspring from mating *bcl-x*$^{flox/+}$ *mcl-1*$^{flox/+}$ *AlbCre* mice and *bcl-x*$^{flox/flox}$ *mcl-1*$^{flox/flox}$ mice were sacrificed at the age of 6 weeks. (A) Western blot of whole liver lysate for the expression of Bcl-xL and Mcl-1. (B) Serum ALT levels. N = 9 mice for each group. *$P < 0.05$ versus the other five groups. (C) Serum levels of caspase-3/7 activity. The levels were normalized to *bcl-x*$^{flox/+}$ *mcl-1*$^{flox/+}$ mice. N = 9 mice for each group. *$P < 0.05$ versus the other five groups. (D) Hematoxylin-eosin and TUNEL staining of the liver sections for *bcl-x*$^{flox/+}$ *mcl-1*$^{flox/+}$ *AlbCre* mice. Findings for *bcl-x*$^{flox/+}$ *mcl-1*$^{flox/+}$ mice are shown as a control. (E) Statistics of TUNEL-positive cells. The number of TUNEL-positive cells was determined in a defined area. N = 5 or 6. *$P < 0.05$. (F) RT-PCR analysis for TNF-α expression. The levels were normalized to the group of *bcl-x*$^{flox/+ \text{ or flox}}$ *mcl-1*$^{flox/+ \text{ or flox}}$. *$P < 0.05$. N = 9.

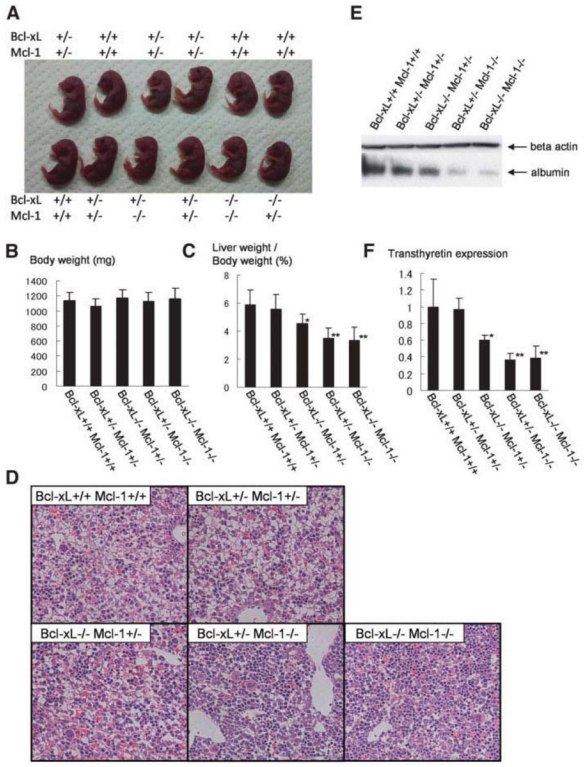

Fig. 4.

Hepatocyte-specific Bcl-xL/Mcl-1– deficient embryos. Offspring from mating *bcl-x*$^{flox/+}$ *mcl-1*$^{flox/+}$ *AlbCre* mice and *bcl-x*$^{flox/flox}$ *mcl-1*$^{flox/flox}$ mice were sacrificed on day 18.5 of gestation. Mice were classified into five groups. The *bcl-x*$^{flox/+\ or\ flox}$ *mcl-1*$^{flox/+\ or\ flox}$ are indicated by Bcl-xL +/+ Mcl-1 +/+; *bcl-x*$^{flox/+}$ *mcl-1*$^{flox/+}$ *AlbCre* are indicated by Bcl-xL +/− Mcl-1 +/−; *bcl-x*$^{flox/flox}$ *mcl-1*$^{flox/+}$ *AlbCre* are indicated by Bcl-xL −/− Mcl-1 +/−; *bcl-x*$^{flox/+}$ *mcl-1*$^{flox/flox}$ *AlbCre* are indicated by Bcl-xL +/− Mcl-1 −/−; *bcl-x*$^{flox/flox}$ *mcl-1*$^{flox/flox}$ *AlbCre* are indicated by Bcl-xL −/− Mcl-1 −/−. The numbers of embryos analyzed were 30 for Bcl-xL +/+ Mcl-1 +/+, 11 for Bcl-xL +/− Mcl-1 +/−, 8 for Bcl-xL −/− Mcl-1 +/−, 9 for Bcl-xL +/− Mcl-1 −/−, and 10 for Bcl-xL −/− Mcl-1 −/−. (A) Gross appearance of embryos. Representative photo for a litter is shown. (B) Body weight. (C) The ratios of liver weight to body weight. *$P < 0.05$ versus Bcl-xL +/+ Mcl-1 +/+; **$P < 0.05$ versus Bcl-xL +/+ Mcl-1 +/+ and Bcl-xL +/− Mcl-1 +/−. (D) Hematoxylin-eosin staining of the liver sections. (E) Western blot of whole-liver lysate for albumin expression. (F) Real-time RT-PCR analysis for transthyretin expression. The levels were normalized to the group of Bcl-xL +/+ Mcl-1 +/+. *$P < 0.05$ versus Bcl-xL +/+ Mcl-1 +/+; **$P < 0.05$ versus Bcl-xL +/+ Mcl-1 +/+ and Bcl-xL +/− Mcl-1 +/−.

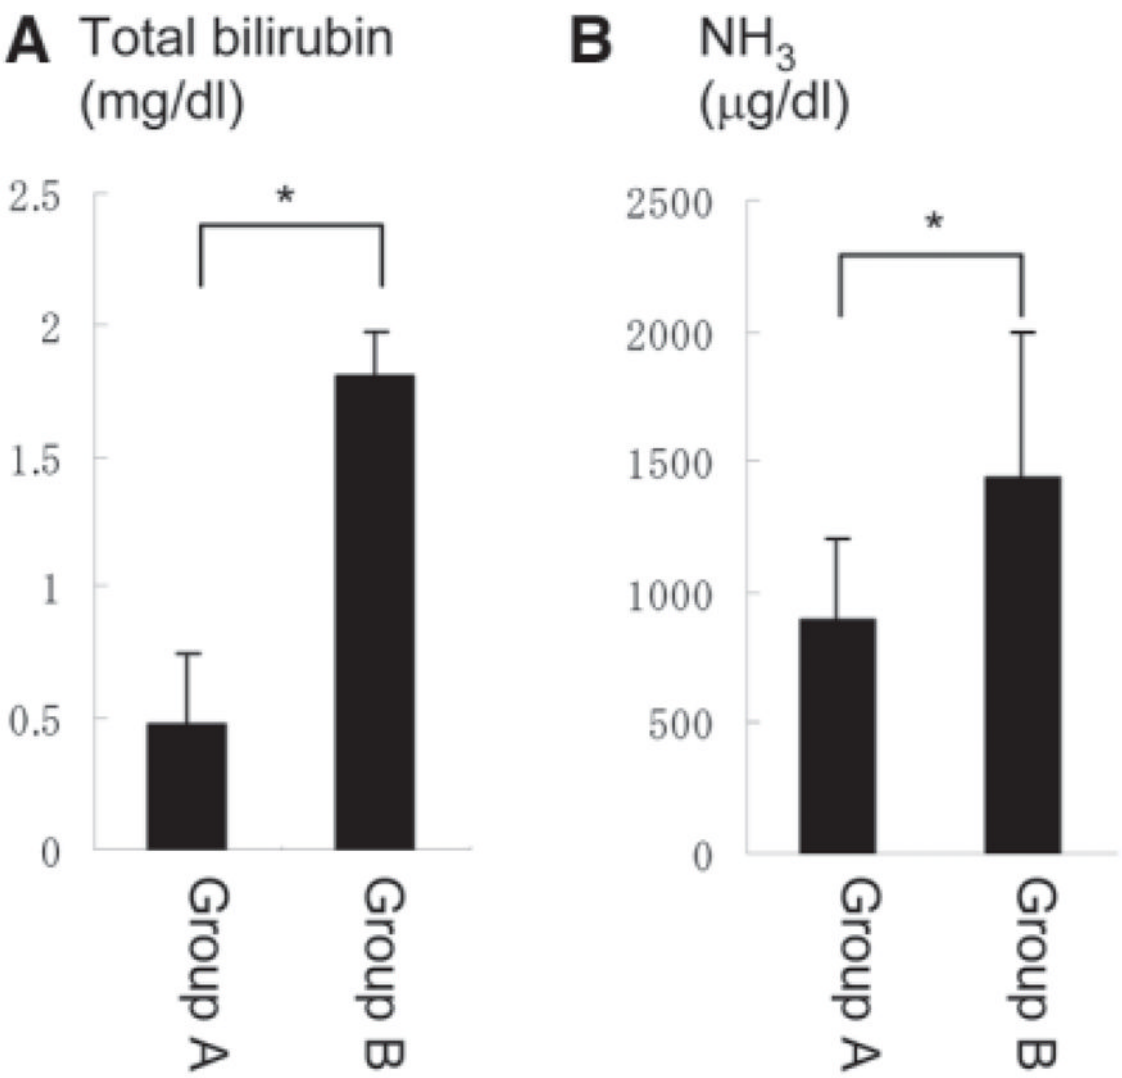

Fig. 5.

Plasma biochemistry of hepatocyte-specific Bcl-xL/Mcl-1– deficient neonates 10 hours after birth. Group A (N = 13) was defined as expected survivors including *AlbCre*-negative mice and *bcl-x*$^{flox/+}$ *mcl-1*$^{flox/+}$ *AlbCre* mice. Group B (N = 6) was defined as expected nonsurvivors including *bcl-x*$^{flox/flox}$ *mcl-1*$^{flox/+}$ *AlbCre*, *bcl-x*$^{flox/+}$ *mcl-1*$^{flox/flox}$ *AlbCre*, *bcl-x*$^{flox/flox}$ *mcl-1*$^{flox/flox}$ *AlbCre*. (A) Plasma total bilirubin levels. **P* < 0.05. (B) Plasma ammonia levels in both groups. **P* < 0.05.

Table 1

Genotyping of Offspring Obtained by Crossing *bcl-x*$^{flox/+}$ *mcl-1*$^{flox/+}$ *AlbCre* Mice and *bcl-x*$^{flox/flox}$ *mcl-1*$^{flox/flox}$ Mice

AlbCre	bcl-x	mcl-1	ED18.5	3 Weeks
−	*flox/+*	*flox/+*	4	14
−	*flox/flox*	*flox/+*	6	17
−	*flox/+*	*flox/flox*	12	17
−	*flox/flox*	*flox/flox*	7	17
+	*flox/+*	*flox/+*	11	22
+	*flox/flox*	*flox/+*	8	0
+	*flox/+*	*flox/flox*	9	0
+	*flox/flox*	*flox/flox*	10	0
	Total		67	87

ED, embryonic day.

Note that each genotype is expected to account for one-eighth of the offspring from this mating.
