Synergy

3CL protease

ABSTRACT

Feline coronavirus infection is common among domestic and exotic felid species and usually associated with mild or asymptomatic enteritis; however, feline infectious peritonitis (FIP) is a fatal disease of cats that is caused by systemic infection with a feline infectious peritonitis virus (FIPV), a variant of feline enteric coronavirus (FECV). Currently, there is no specific treatment approved for FIP despite the importance of FIP as the leading infectious cause of death in young cats. During the replication process, coronavirus produces viral polyproteins that are processed into mature proteins by viral proteases, the main protease (3C-like [3CL] protease) and the papain-like protease. Since the cleavages of viral polyproteins are an essential step for virus replication, blockage of viral protease is an attractive target for therapeutic intervention. Previously, we reported the generation of broad-spectrum peptidyl inhibitors against viruses that possess a 3C or 3CL protease. In this study, we further evaluated the antiviral effects of the peptidyl inhibitors against feline coronaviruses, and investigated the interaction between our protease inhibitor and a cathepsin B inhibitor, an entry blocker, against a feline coronavirus in cell culture. Herein we report that our compounds behave as reversible, competitive inhibitors of 3CL protease, potently inhibited the replication of feline coronaviruses (EC_{50} in a nanomolar range) and, furthermore, combination of cathepsin B and 3CL protease inhibitors led to a strong synergistic interaction against feline coronaviruses in a cell culture system.

1. Introduction

Coronaviruses are single stranded positive sense RNA viruses that contain the largest non-segmented RNA virus genome. Coronaviruses are responsible for highly prevalent diseases in humans and animals, and are divided into the groups alpha, beta, and gamma, based on antigenic and genetic criteria, of which alpha and beta coronaviruses infect mammals (Homes, 2001). Severe acute respiratory syndrome coronavirus (SARS-CoV) is classified into the beta group of coronaviruses. Feline coronaviruses belong to alpha coronaviruses and affect animals in the family Felidae, including cheetahs, wildcats, lions and leopards (Heeney et al., 1990; Kennedy et al., 2002). Feline coronavirus is further classified as serotype I or II. Feline serotype I and canine coronaviruses are considered to have originated from a common ancestor. Feline coronavirus serotype II appears to be derived from recombination with canine coronavirus and feline coronavirus serotype I in the S (spike) protein

(Herrewegh et al., 1998; Motokawa et al., 1996). Feline coronavirus serotype I is more prevalent than serotype II, and feline coronaviruses of both serotypes can cause mild or asymptomatic enteritis and feline infectious peritonitis (FIP) in cats (Benetka et al., 2004; Kummrow et al., 2005; Pedersen et al., 1984a). FIP is a fatal disease in cats and currently one of the leading infectious causes of fatality among young cats in multiple cat households and shelters (Pedersen, 2009). Feline enteric coronavirus (FECV) causes asymptomatic to mild enteritis among cats with a high prevalence (Pedersen et al., 2008; Vogel et al., 2010). Unlike FECV which is confined to the intestinal epithelium, FIP virus (FIPV) gains ability to replicate in macrophages and monocytes by mutation of endogenous FECV and can spread through the entire body. The progression to FIP is also influenced by the host's immune responses; a weak or defect in cell-mediated immune response is associated with the development of FIP (Pedersen, 2009). Despite the fatal nature and increasing incidence of FIP, no effective prophylactic or therapeutic agent is currently available for FIPV.

Coronaviruses have club-shaped S proteins on the envelope, which bind to the cells and undergo membrane fusion to gain entry into the cytoplasm. The cleavage of S proteins varies among coronaviruses. In some coronaviruses including SARS-CoV and murine hepatitis virus (MHV)-2, S proteins are cleaved by cellular

cathepsins that are cysteine proteases typically present within the endosome/lysosome in the cell cytoplasm (Qiu et al., 2006; Simmons et al., 2005). FIP and FECV are also found to be highly dependent on the presence of cathepsin B for the cleavage of their S proteins, which enables cell entry for virus replication (Regan et al., 2008). The importance of the presence of cathepsin function in the replication of feline coronaviruses is demonstrated by the inhibition of some serotype I and II feline coronaviruses, including WSU-1683, WSU-1146, and DF2 strains, by a cathepsin B inhibitor CA074-Me and an irreversible non-specific cysteine inhibitor E64d by inhibiting the cleavage of S proteins (Regan et al., 2008). This result indicates that cathepsin B may serve as a potential target for the development of therapeutic drugs against feline coronaviruses.

Following entry into the cells, coronaviruses express polyproteins (pp1a and pp1b), which are cleaved by viral proteases into intermediate and mature nonstructural proteins. The viral proteases involved in the cleavage of the polyproteins are papain-like proteases (PL1pro and PL2pro) and a 3C-like (3CL) protease. The papain-like proteases cleave the N-proximal region of pp1a/pp1ab, and 3CL protease cleaves the viral polyprotein at 11 conserved interdomain junctions (Ziebuhr et al., 2000). Coronavirus proteases, like many other viral proteases such as those of human immunodeficiency virus-1 and hepatitis C virus, for which commercial protease inhibitors are available, are highly effective regulators of virus replication. Coronavirus 3CL protease is a cysteine protease that shares common characteristics in structural and functional properties with the 3CL or 3C proteases of noroviruses and picornaviruses, respectively; they possess chymotrypsin-like folds, cysteine residue as a nucleophile, and conserved active sites. Viral 3CL or 3C protease plays an essential role in viral replication; consequently, it is an attractive target for the development of antiviral drugs. Previously, we reported the generation of new peptidyl inhibitors against norovirus 3CL protease and their broad spectrum activity against viruses that possess 3C or 3CL proteases, including feline coronavirus (Kim et al., 2012; Tiew et al., 2011). In this study, we further studied the reversibility and the mode of inhibition of our 3CL protease inhibitors, and compared the antiviral effects of the 3CL protease inhibitors (GC373 and GC376) and cathepsin inhibitors against the replication of feline coronaviruses in cells. We also studied the combined antiviral effects of GC373 and CA074-Me, a cathepsin B inhibitor, against a feline coronavirus in cell culture.

In summary, we have demonstrated that the peptidyl transition state inhibitors used in this study are reversible, competitive inhibitors of 3CL protease and potently inhibit the replication of feline coronaviruses in cell culture with an EC_{50} (the effective concentration for 50% inhibition of viral replication) in a nanomolar range. Furthermore, combined treatment of CA074-Me and GC373 in cells exhibited a strong synergistic activity against a feline coronavirus. These results indicate that these 3CL protease inhibitors have a potential to be developed as antiviral drugs for feline coronaviruses as a single agent or in combination with an entry blocker.

2. Materials and methods

2.1. Compounds

GC373 and GC376 compounds were synthesized as previously described (Tiew et al., 2011) (Fig. 1). Cathepsin B inhibitor CA074-Me [L-3-*trans*-((propylcarbonyl) oxirane-2-Carbonyl)-L-isoleucyl-L-proline methyl ester] and a pan-cysteine cathepsin inhibitor E64d [(2S,3S)-*trans*-epoxysuccinyl-L-leucylamido-3-methylbutane ethyl ester] were purchased from Calbiochem (Darmstadt, Germany).

2.2. The expression and purification of transmissible gastroenteritis virus (TGEV) 3CL protease

The 3CL proteases are highly conserved among all coronaviruses, and feline coronavirus 3CL protease is closely related to TGEV 3CL protease (Hegyí et al., 2002) (Fig. 2). Therefore, we cloned and expressed the TGEV 3CL protease for the fluorescence resonance energy transfer (FRET) assay. The cDNA encoding the full length of 3CL protease of TGEV Miller strain was amplified with RT-PCR as previously described (Anand et al., 2002). The primers contained the nucleotide sequence of the 3CL protease for cloning as well as the nucleotides for 6 Histidine in the forward primer. The forward and reverse primers were TGEVPro-6hisXba-F (tctagaag-gagatataccatgcatcatcatcatcattcagggtttacggaaaatggc) and TGEV-Pro-Xho-R (ctcgagtcactgaagattacaccatcac). The amplified product was subcloned to pET-28a(+) vector (GenScript, Piscataway, NJ). The expression and purification of the 3CL protease was performed with a standard method described previously by our lab (Chang et al., 2012b; Takahashi et al., 2012; Tiew et al., 2011).

2.3. Enzymatic activity assay

3CL protease inhibitors, GC373 and GC376, and commercial cathepsin inhibitors, CA074-Me and E64d, were prepared in DMSO as stock solutions (10 mM), and further diluted in assay buffer consisting of 20 mM HEPES, 0.4 mM EDTA, 30% glycerol, 120 mM NaCl, and 4 mM DTT at pH 6. TGEV 3CL protease at a final concentration of 0.1–0.2 μ M and the substrate (Edans-Val-Asn-Ser-Thr-Leu-Gln/Ser-Gly-Leu-Arg-Lys[Dabcyl]-Met) (Kuo et al., 2004) at 10 μ M were used for the studies. Compounds at various concentrations (0–50 μ M) were pre-incubated with TGEV 3CL protease in 25 μ l for 20 min at 37 $^{\circ}$ C, and the same volume of substrate was added to the mixture, or the compound was added to the protease immediately before the substrate was added to the enzyme/inhibitor mixture in 96-well black plate. The mixtures were then further incubated at 37 $^{\circ}$ C for 60 min, and fluorescence readings were obtained on a microplate reader at 360 nm excitation and 480 nm emission wavelengths. The relative fluorescence units (RFU) were calculated by subtracting background (substrate control well without protease) from the fluorescence readings. The dose-dependent FRET inhibition curves were fitted with variable slope (four parameters) using GraphPad Prism software 5 (La Jolla, CA) in order to determine the compound concentration that gives a half-maximum response (IC_{50}). In separate experiments, TGEV 3CL protease (0.2 μ M) was incubated with serially diluted GC373 (0–2 μ M) in 25 μ l of assay buffer and incubated at 37 $^{\circ}$ C for 20 min, followed by the addition of various concentrations of substrates (10–200 μ M). The mixtures were incubated at 37 $^{\circ}$ C, and fluorescence readings were obtained on a microplate reader at every 5 min for up to 30 min. The correction factors to compensate for the inner filter effects were determined empirically as described previously (Chang et al., 2012b; Cuerrier et al., 2005; Jaulent et al., 2007).

The kinetic constant K_m was determined by the fitting initial rates to the Michaelis–Menten equation using GraphPad Prism software. Lineweaver–Burk plots were constructed using GraphPad Prism software to determine K_i values as well as the type of enzyme inhibition. Lastly, recovery of enzymatic activity of TGEV 3CL protease over time (rapid dilution experiments) was studied to demonstrate reversible binding of GC373 to TGEV 3CL protease (Copeland, 2005; Xie et al., 2011). Rapid dilution experiments were performed by incubating TGEV 3CL protease at 100 times the concentration that is normally used in a reaction with DMSO or GC373 at concentrations approximately 10 times greater than the IC_{50} value (10 μ M) for 30 min at 37 $^{\circ}$ C. After incubation, the mixture was diluted 100-fold in reaction buffer to normal reaction condition before the substrate was added. The fluorescence readings were obtained on a microplate reader over time, and the progress curves were generated.

2.4. Cells, viruses, and reagents

Crandell Rees feline kidney (CRFK) cells were maintained in minimal essential medium containing 2–5% fetal bovine serum and antibiotics (chlortetracycline [25 μ g/ml], penicillin [250 U/ml], and streptomycin [250 μ g/ml]). Cell culture-adapted feline coronaviruses WSU 79-1146 and WSU 79-1683 strains were purchased from ATCC (Manassas, VA).

2.5. Antiviral effects of the protease and cathepsin inhibitors against feline coronaviruses in cells

Virus infection was performed as follows: solvent (0.1% DMSO), CA074-Me, E64d, GC373 or GC376 was added at various concentrations to two-day old monolayers of CRFK cells prepared in 6 well

plates. The cells were further incubated in the presence of each compound or solvent for 2 h at 37 °C, or the compound was added at the same time with virus inoculation. WSU-1147 or WSU-1683 was inoculated to the cells at a multiplicity of infection (MOI) of 0.05 or 5 (MOI 5 for Western blot analysis). The virus infected cells were incubated in the presence of a compound for up to 2 days, and EC_{50} was determined by the $TCID_{50}$ method (Reed and Muench, 1938).

2.5.1. Western blot analysis

Cell lysates from CRFK cells were prepared by adding sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS–PAGE) sample buffer containing 2% β -mercaptoethanol and sonication for 20 s. The proteins were then resolved in a 10% Novex Bis-Glycin gel (Invitrogen, Carlsbad, CA) and transferred to a nitrocellulose membrane. The transferred nitrocellulose membranes were incubated with primary antibodies to coronavirus nucleocapsid protein (Biocompare, Windham, NH) or β -actin as a loading control overnight, and then with the secondary antibodies conjugated with peroxidase for 2 h. Following incubation with a chemiluminescent substrate (SuperSignal West Pico Chemiluminescent Substrate, Pierce biotechnology, Rockford, IL), the signals were detected on X-ray films.

2.5.2. $TCID_{50}$ method

A standard $TCID_{50}$ method with the 10-fold dilution of each sample was used for virus titration (Reed and Muench, 1938).

2.5.3. Nonspecific cytotoxic effect

We determined the toxic concentration for 50% cell death (TC_{50}) for each compound in CRFK cells. Confluent cells grown in 24-well plates were treated with various concentrations of compounds at up to 100 μ M for cathepsin inhibitors and 500 μ M for 3CL protease inhibitors for 24 or 48 h. Cell cytotoxicity was measured by a Cyto-Tox 96[®] non-radioactive cytotoxicity assay kit (Promega, Madison, WI) and crystal violet staining. The *in vitro* therapeutic index (TI) was calculated by dividing TC_{50} by EC_{50} .

2.6. Combination treatment of a cathepsin B inhibitor, CA074-Me, and GC373

The CRFK cells were incubated with GC373 (0.02–0.2 μ M), CA074-Me (0.5–5 μ M), or the combinations of GC373 (0.02–0.2 μ M) and CA074-Me (0.5–5 μ M) for 2 h at 37 °C, prior to inoculation of WSU-1146 at an MOI of 0.05. After 24 h of incubation, virus replication was assessed with virus titration using the $TCID_{50}$ method. Drug–drug interactions were analyzed by the three-dimensional model of Prichard and Shipman (Prichard and Shipman, 1990), using the MacSynergy II software at 95% confidence limits. Theoretical additive interactions were calculated from the dose–response curve for each compound individually, and the calculated additive surface was subtracted from the experimentally determined dose–response surface to give regions of synergistic or antagonistic interactions. The resulting surface appears as horizontal plane at 0% of synergy if the interactions of two compounds are additive. Any peak above or below this plane indicates synergy or antagonism, respectively.

3. Results

3.1. Effects of the 3CL protease inhibitors on the protease activity in the FRET-based assay

The protease inhibition assay was performed using the fluorescence substrate derived from a cleavage site of SARS-CoV to exam-

ine the inhibition of the 3CL protease by GC373 and GC376. The inhibitory effects of each compound at 50 μ M (final concentration) on the activity of TGEV 3CL protease are shown in Fig. 3A. Cathepsin B inhibitor CA074-Me and pan-cysteine cathepsin inhibitor E64d were included as controls. GC373 and GC376 remarkably inhibited the activity of TGEV 3CL protease at 50 μ M, but the cathepsin inhibitors did not (Fig. 3A). The dose-dependent inhibition of TGEV 3CL protease activities by GC373 with or without pre-incubation of the compound with the protease is shown by open circles and filled squares, respectively, in Fig. 3B. The IC_{50} values of GC373 and GC376 against the 3CL protease determined in the FRET assay were 0.98 and 0.82 μ M, respectively, when the compounds were pre-incubated with the protease. The IC_{50} values of GC373 and GC376 against the 3CL protease without pre-incubation were 3.2 and 2.7 μ M, respectively, indicating that pre-incubation of the protease with the 3CL inhibitors caused about a 3-fold increase in inhibitor potency. The K_m value for the fluorogenic substrate was 15.52 μ M. The Lineweaver–Burk plots (Fig. 3C) suggested competitive inhibition of the proteolytic cleavage of the substrate by GC373 with a K_i value of 0.43 ± 0.06 μ M. Reversibility of our compound was determined by the rapid dilution experiments. As shown in Fig. 3D, the enzymatic activity of the 3CL protease incubated with GC373 at $10 \times IC_{50}$ concentration recovered after 100-fold dilution of the protease/inhibitor mixture. At the final concentration after the dilution, the inhibitor concentration is 10-fold below the IC_{50} . The recovery of enzymatic activity over time indicates that the compound was a reversible inhibitor.

3.2. Effects of the 3CL protease inhibitors and cathepsin inhibitors against the replication of feline coronaviruses in cells

The antiviral effects of the 3CL protease inhibitors and cathepsin inhibitors were studied in cell culture. The replication of WSU-1683 and WSU-1146 were markedly inhibited by the presence of GC373, GC376, CA074-Me, or E64d (Tables 1 and 2, Fig. 4). However, suppression of virus replication by the 3CL protease inhibitors was more potent than those by CA074-Me and E64d at 24 and 48 h, indicated by the EC_{50} values (Table 1). Notably, the antiviral activities of CA074-Me and E64d decreased substantially over time (Table 1). When the 3CL protease inhibitors were added to the cells at the same time of virus infection, the EC_{50} values of the compounds increased by 2- to 3.75-fold, compared to those obtained from pre-incubation of cells with the compounds (Table 2). The antiviral effects of the 3CL protease inhibitors were selective; they were not active against unrelated viruses such as influenza virus and porcine respiratory and reproductive syndrome virus (data not shown). The antiviral activity of GC373 and GC376 was not due to nonspecific cytotoxicity since the 3CL protease inhibitors did not show any cytotoxicity, in various cells even at 500 μ M. The cathepsin inhibitors CA074-Me and E64d also did not show any toxicity at 100 μ M. The *in vitro* therapeutic indices calculated from the ratio of EC_{50}/TC_{50} of cathepsin and 3CL protease inhibitors are at least 25 and 2900, respectively, at 24 h post virus infection. These results demonstrate that the replication of feline coronaviruses is effectively inhibited by the 3CL protease inhibitors with an excellent safety margin in cells.

3.3. Effects of the combined treatment of GC373 and CA074-Me in the replication of WSU-1146

Combination treatment of GC373 and CA074-Me was performed to investigate the interactions of the two compounds with different modes of inhibition against the replication of WSU-1146. The effects of combination were determined to be strongly synergistic, as analyzed in a mathematical model based on the MacSynergy. Antiviral synergy was observed between GC373 and CA074-

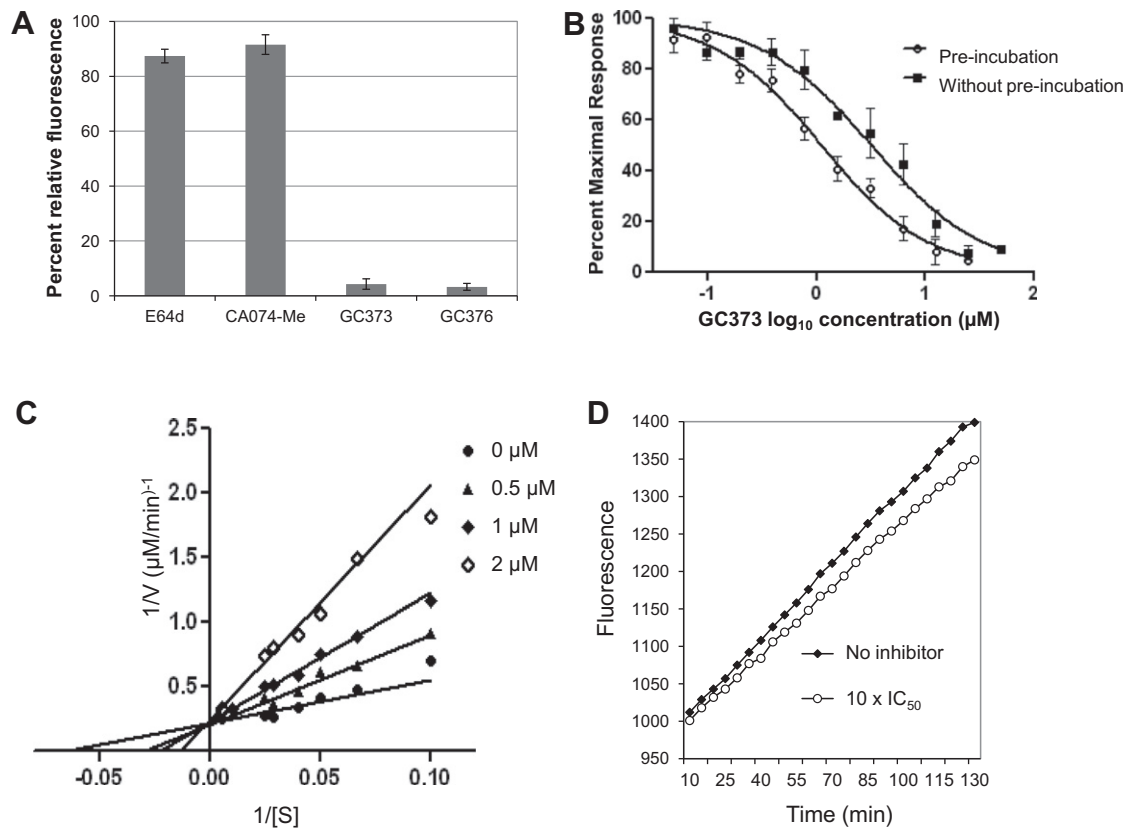

Fig. 3. FRET-based protease assay. (A) The effects of the 3CL protease inhibitors, GC373 and GC376, a cathepsin B inhibitor CA074-Me, and a pan-cysteine cathepsin inhibitor E64d on the activity of TGEV 3CL protease in the FRET-protease assay. TGEV 3CL protease was incubated with each compound at 50 μM for 20 min before the substrate was added to the mixture. Each bar represents the percent relative fluorescence (mean \pm standard error of the mean [SEM]). (B) A plot of \log_{10} GC373 concentration versus percent maximal response. TGEV 3CL protease was incubated with GC373 for 20 min at increasing concentrations prior to addition of substrate (open circles), or GC373 was added at the same time with the substrate (filled squares). The fluorescence signals were detected by a spectrophotometer, and the data are then plotted as percent maximal response against the \log concentrations of the compound. The data points represent the percent maximal response (mean \pm SEM). (C) Lineweaver–Burk plots of kinetic data of the TGEV 3CL protease incubated with various concentrations of GC373. The enzymatic activities were measured using 10–200 μM substrate in the absence (filled circles) or presence of 0.5 (filled triangles), 1 (filled diamonds), and 2 (open diamonds) μM GC373. (D) Progress curves for the recovery of enzymatic activities of TGEV 3CL protease after 3CL protease–GC373 complex was rapidly diluted to the normal assay solution. TGEV 3CL protease was incubated with DMSO (filled diamonds) or 10 μM (open circles) GC373 for 20 min, then rapidly diluted 100-fold in reaction buffer prior to substrate addition, and assayed for enzymatic activity.

Table 1

The effects of GC373, GC376, CA074-Me and E64d on the replication of feline coronaviruses in CRFK cells pre-incubated with the compounds.

	Inhibition [EC_{50} (μM)] against feline coronaviruses ^a			
	WSU-1683		WSU-1146	
	24 h	48 h	24 h	48 h
GC373	0.04 \pm 0.01	0.09 \pm 0.01	0.07 \pm 0.04	0.43 \pm 0.35
GC376	0.17 \pm 0.11	0.28 \pm 0.10	0.15 \pm 0.05	0.30 \pm 0.10
CA074-Me	4.0 \pm 0.71	>10	2.5 \pm 1.4	>10
E64d	2.3 \pm 0.28	>10	1.45 \pm 0.49	>10

^a The mean and standard error of the mean (SEM) of the EC_{50} values for virus inhibition at 24 and 48 h post infection are summarized. CRFK cells were incubated with each compound for 2 h before virus infection at an MOI of 0.05 and further incubated in the presence of each compound for up to 48 h. Virus titers were determined using the TCID₅₀ method for the calculation of the EC_{50} values.

Table 2

The effects of GC373 and GC376 on the replication of feline coronaviruses in CRFK cells without pre-incubation.

	Inhibition [EC_{50} (μM)] against feline coronaviruses ^a	
	WSU-1683	WSU-1146
GC373	0.15 \pm 0.18	0.12 \pm 0.09
GC376	0.40 \pm 0.21	0.30 \pm 0.14

^a The mean and standard error of the mean (SEM) of the EC_{50} values for virus inhibition at 24 h post infection are summarized. Each compound was added to CRFK cells at the same time with virus inoculation at an MOI of 0.05, and further incubated in the presence of each compound for up to 24 h. Virus titers were determined using the TCID₅₀ method for the calculation of the EC_{50} values.

Me with an average Synergy₉₅ volume of 99.3 $\mu\text{M}^2\%$ at a 95% confidence interval over two experiments (Fig. 5A and B, and Table 3). Absolute values over 25 $\mu\text{M}^2\%$ indicate significant values of synergy. For example, when virus-infected CRFK cells were treated with GC373 at 0.05 μM or CA074-Me at 1 μM , each resulted in a 0.5 \log_{10} reduction of virus titers; in contrast, the combination of the two led to a 2 \log_{10} viral titer reduction, which was much more effective than either compound alone (indicated as synergy % in Table 3).

4. Discussion

Feline infectious peritonitis is believed to be caused by infectious peritonitis virus arising by changing tissue tropism from intestinal cells to macrophages by mutations of feline enteric coronavirus in individual cats (Chang et al., 2012a; Vennema et al., 1998). The underlying mechanisms that allow the tissue tropism change is reported to be associated with mutations in the S and open reading frame 3c genes and the aberrant immune response of the host, but the detailed mechanism of the altered tropism has not been clearly established (Chang et al., 2012a; Chang

Fig. 4. Western blot analysis of the effects of GC373, GC376, and CA074-Me on the accumulation of coronavirus nucleocapsid proteins in CRFK cells infected with WSU-1146. CRFK cells were treated with 0.1% DMSO, GC373, GC376, or CA074-Me for 2 h, followed by virus infection at an MOI of 5, and further incubated for 12 h. Cell extracts were analyzed by Western blot for expression of coronavirus nucleocapsid protein and β -actin was loaded as an internal control. Numbers below each lane indicate the values of coronavirus nucleocapsid proteins normalized to β -actin obtained with densitometric scanning using TotalLab Quant software (TotalLab Ltd.).

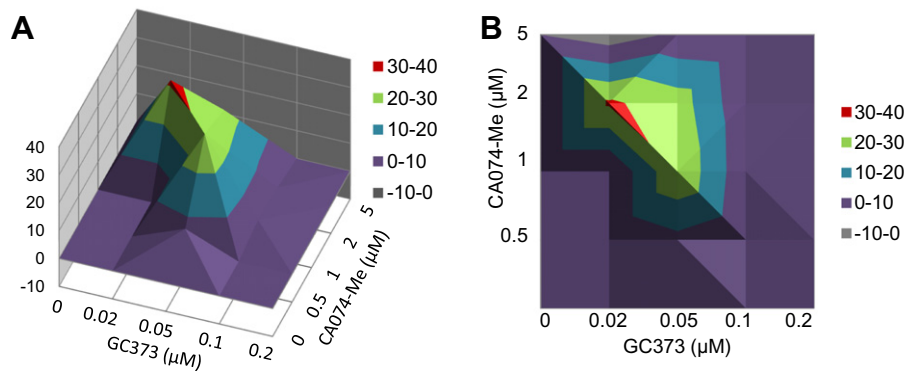

Fig. 5. Three-dimensional plots showing the interaction of GC373 and CA074-Me on the replication of WSU-1146. (A and B) CRFK cells were incubated with CA074-Me (0.5–5 μ M), GC373 (0.02–0.2 μ M) or combinations of CA074-Me and GC373 for 2 h before the virus was inoculated in the cells at an MOI of 0.05. The cells were further incubated in the presence of each compound for 24 h, and virus replication was measured by the TCID₅₀ method. Drug–drug interactions were analyzed by the three-dimensional model of Prichard and Shipman, using the MacSynergy II software at a 95% confidence interval. Surface above the plane of 0% synergy in the plot indicate synergy. (B) Contour plots (two-dimensional representations of the data) for easier identification of the concentration ranges where statistically significant synergistic or antagonistic effects occurred.

et al., 2011; Pedersen et al., 2012; Poland et al., 1996; Vennema et al., 1998). The feline enteric coronaviruses are present ubiquitously in the environment and easily transmitted via a fecal–oral route. Thus elimination of feline coronavirus from multi-cat environments can be challenging. Although therapeutic measures for FIP are highly desirable to control this fatal disease, limited information on the effective treatment for FIP is available (Legendre and Bartges, 2009; Ritz et al., 2007). The general treatment options for FIP are supportive therapy, including the use of immunosuppressants such as glucocorticoids, and antibiotics (Hartmann and Ritz, 2008). Other agents that have been used include interferons, tumor necrosis factor- α inhibitor, propentofylline, and polypropenyl immunostimulant (Ishida et al., 2004; Legendre and Bartges, 2009; Ritz et al., 2007). However, the therapeutic efficacy of those immune modulating agents was shown to be ineffective or needs further investigation in controlled trials (Fischer et al., 2011; Ritz et al., 2007). Ribavirin was reported to reduce the replication of FIPV with an IC₅₀ of 10 μ M and a TC₅₀ of 69 μ M, and a later study using specific pathogen free cats infected with FIPV showed that ribavirin treatment at 16.5 mg/kg was not effective at reducing fatality or severity of symptoms (Weiss et al., 1993). In addition,

studies on the antiviral agents that directly or indirectly target virus components and/or replication steps are very limited (Barlough and Shacklett, 1994; Hsieh et al., 2010).

Our group has previously reported a series of new 3CL protease inhibitors targeting the 3CL protease of norovirus (Tiew et al., 2011). Coronavirus 3CL protease is classified as a chymotrypsin-like cysteine protease and shares a remarkable degree of conservation of the active site with norovirus 3CL protease. Our dipeptidyl 3CL protease inhibitors incorporate in their structure a glutamine surrogate and a leucine residue that correspond to the P1 and P2 sites in the substrate (Tiew et al., 2011). The amino acid residues in the substrate are designated as P1, P2, etc., starting at the scissile bond and counting towards the N-terminus. Likewise, the amino acid residues reside on the C-terminus side of the scissile bond are designated as P1', P2', etc (Schechter and Berger, 1967). The 3CL protease inhibitors were originally developed by our group by reflecting the substrate specificity of norovirus 3CL protease where the most frequently found residues in the P1 and P2 positions at the cleavage sites are glutamine and leucine, respectively. These amino acid residues in the P1 and P2 sites are also conserved among coronaviruses, including TGEV, FECV, FIPV, MHV, and

Table 3

Summary of MacSynergy analysis on the combination effects of GC373 and CA074-Me against the replication of FIPV-1146 in CRFK cells.

CA074-Me (μM)	GC373 (μM)					Synergy volume at 95% CI ($\mu\text{M}^2\%$) [*]	Antagonism volume at 95% CI ($\mu\text{M}^2\%$)
	0	0.02	0.05	0.1	0.2

human coronaviruses (Hegyí and Ziebuhr, 2002; Yang et al., 2005). These highly conserved features among viruses encoding containing 3C or 3CL proteases led to the finding that our dipeptidyl compounds potentially inhibit the replication of noroviruses, picornaviruses, and coronaviruses including feline coronaviruses in cells (Kim et al., 2012). These peptidyl compounds were previously demonstrated to target coronavirus 3CL protease by the FRET protease assay and the crystal structure of TGEV 3CL protease-GC376 complex (Kim et al., 2012). GC373 possesses aldehyde as a potent electrophile that reacts with a cysteine (the nucleophilic sulfur) in the active site of virus protease in a reversible manner, and the bisulfite adduct warhead of GC376 was synthesized from the precursor aldehyde (Fig. 1). Since the bisulfite adduct is converted to the aldehyde form to form a covalent bond with cysteine in the active site of virus protease, based on the preliminary results in rats and the crystal structure of the complex of GC376 and TGEV 3CL protease, it is likely that GC376 behaves as a prodrug of the aldehyde counterpart (Kim et al., 2012).

In this study, we compared the antiviral activities of our dipeptidyl compounds and a cathepsin B inhibitor CA074-Me and non-specific cysteine cathepsin inhibitor E64d against feline coronaviruses WSU-1683 and WSU-1146. Both virus strains are cell culture adapted type II feline coronaviruses, of which WSU-1146 is confirmed to cause FIP in experimental settings (Pedersen et al., 1984b). WSU-1683 was originally thought to be a feline enteric coronavirus since it induced inapparent to mild enteritis without causing systemic infection in experimentally infected cats (Pedersen et al., 1984b). However, the subsequent sequence analysis studies on the mutations of genes that may contribute to development of FIPV from FECV suggest that WSU-1683 may have lost its virulence as FIPV and reverted to FECV biotype (Chang et al., 2010; Herrewegh et al., 1995; Pedersen, 2009; Pedersen et al., 2008). In our study, cathepsin inhibitors CA074-Me and E64d significantly inhibited the replication of feline coronaviruses at 24 h, although their potency was 13- to 100-fold lower than that of the 3CL protease inhibitors. However, a rapid loss of activity of CA074-Me and E64d was observed over time in cell culture without daily addition of the compounds, compared to the 3CL protease inhibitors. The shorter duration of the activity of cathepsin inhibitors against viral replication is speculated to be viruses overcoming the antiviral blockade imposed by inhibition of cathepsin activity by resynthesis of uninhibited cathepsins or the relative instability of the cathepsin inhibitors in media. The antiviral effects of non-specific cathepsin inhibition by E64d against feline coronaviruses were more potent than the inhibition by cathepsin B at 24 h post infection, which may be explained by differences in affinity for the protease, stability of compounds, or potential presence of cathepsins other than cathepsin B that are able to process the viral polyproteins. It was reported previously that FIPV and FECV differ in their requirement of cathepsins for the cleavage of S protein to gain entry into cells; both cathepsin B and L are required for FECV, but cathepsin L is dispensable for FIPV strains in cells (Regan et al., 2008), suggesting the different requirement for cathepsins among the virus strains. When our 3CL protease inhibitors were added to the cells at the same time

of virus infection, the antiviral activity of the compounds was reduced, compared to 2 h pre-incubation of the cells with the inhibitors, reflected by the increase of the EC_{50} values by up to 3.7-fold. In the FRET assay, the IC_{50} values of GC373 and GC376 against the 3CL protease also increased by about 3-fold. However, the antiviral activities of GC373 and GC376 in cells were still potent with nanomolar EC_{50} values, even when the inhibitors were added to the cells at the time of virus inoculation.

Our X-ray crystallographic studies previously showed that GC376 binds to the active site and forms a reversible covalent bond with a cysteine Cys residue in the active site of 3C or 3CL proteases of Norwalk virus, poliovirus, and TGEV (Kim et al., 2012). In this study, the kinetic analysis of TGEV 3CL protease and GC373 revealed the reversible, competitive nature of the inhibitor. We have not examined our 3CL protease inhibitors against the serotype I feline coronaviruses for their antiviral activities in this study. However we expect the 3CL protease inhibitors to be effective against serotype I feline coronaviruses since the 3CL protease is conserved among coronaviruses, and the 3CL protease inhibitors also inhibited the replication of TGEV and MHV in our previous study (Kim et al., 2012).

Since our 3CL protease inhibitors and CA074-Me act on different targets, we subsequently investigated the effects of the combined treatment of GC373 and CA074-Me against a feline coronavirus in cells. The analysis of the drug-drug combination at the 95% confidence interval by MacSynergy software showed the synergy volume of 99.3 $\mu\text{M}^2\%$. Only small volume of antagonism (-5.79 $\mu\text{M}^2\%$) was observed when a high concentration of CA074-Me (5 μM) were added to the cells containing GC373 (Fig. 5, Table 3). At high concentrations, synergic activity was reduced as the antiviral response by single treatment reached high, and the synergy was most evident at mid range of compound concentrations used. We found no significant synergy of drug cytotoxic effects at the concentrations used. Our results showed the entry blocker and the protease inhibitor that work at the different stages of virus life cycle act synergistically at the concentrations shown. The favorable drug-drug interactions observed with a feline coronavirus suggest a potential use of combination of compounds that target the host factor involved in virus entry and the virus protease for feline coronavirus infection.

In summary, the 3CL protease inhibitors used in this study were found to be highly effective against feline coronaviruses in cells and the antiviral effects of those 3CL protease inhibitors were more profound than inhibition of cathepsins. Strong synergic effects were observed in combination treatment of a cathepsin B inhibitor and our 3CL protease inhibitor. These findings underscore the effectiveness of our 3CL protease inhibitors for feline coronavirus infection and potential use of 3CL protease inhibitors as a single therapeutic agent or in combination with cathepsin B inhibitors.
