Background: Increased Fap1 expression in chronic myeloid leukemia (CML) is associated with Fas resistance.

Results: Fap1 also increases β catenin activity in CML by inactivating Gsk3 β , a serine/threonine kinase that effects inhibitory phosphorylation of β catenin.

Conclusion: Fap1 influences cell proliferation and survival by regulating β catenin protein stability.

Significance: Fap1 contributes to the pathogenesis of CML by inhibiting apoptosis and increasing β catenin activity.

Increased β catenin activity correlates with leukemia stem cell expansion and disease progression in chronic myeloid leukemia (CML). We found previously that expression of the CML-related Bcr-abl oncoprotein in myeloid progenitor cells increases expression of Fas-associated phosphatase 1 (Fap1). This resulted in Fap1-dependent resistance to Fas-induced apoptosis in these cells. Fap1 also interacts with the adenomatous polyposis coli (Apc) protein, but the functional significance of this interaction is unknown. Apc participates in a complex that includes glycogen synthase kinase β (Gsk3 β) and β catenin. Assembly of this complex results in phosphorylation of β catenin by Gsk3 β , which facilitates β catenin ubiquitination and degradation by the proteasome. In this study, we found increased association of Fap1 with the Apc complex in Bcr-abl⁺ myeloid progenitor cells. We also found Fap1-dependent inactivation of Gsk3 β and consequent stabilization of β catenin in these cells. Consistent with this, Bcr-abl⁺ cells exhibited a Fap1-dependent increase in β catenin activity. Our studies identified Fap1-dependent Gsk3 β inactivation as a molecular mechanism for increased β catenin activity in CML.

Fap1 is a ubiquitously expressed protein tyrosine phosphatase (PTP)² that interacts with the C terminus of Fas (1, 2). This interaction results in Fas dephosphorylation and inhibition of Fas-induced apoptosis. The interaction of Fap1 with Fas is blocked by a tripeptide representing the Fas-C terminus (the Serine-Leucine-Valine peptide), and *in vitro* treatment of Fas-resistant cells with this peptide increases sensitivity to Fas-induced apoptosis (2–4). Fap1 also interacts with other proteins, including RapGEF6 and adenomatous polyposis coli (Apc) (5, 6). Fap1 interacts with the C termini of these partners through

the same domain that mediates Fas interaction. The functional significance of these Fap1 interactions is unknown, and Fas is the only known substrate for Fap1-PTP activity.

Chronic myeloid leukemia (CML) is characterized by translocations involving chromosomes 9 and 22 that produce the Bcr-abl oncoprotein. Previous investigations characterized the CML leukemia stem cell (LSC) as a granulocyte-monocyte progenitor (GMP) with increased β catenin activity (7, 8). These investigators found an association between increasing β catenin activity in the bone marrow and disease progression in human CML (7).

The human CML LSC is also characterized by decreased expression of the interferon consensus sequence binding protein (Icsbp, also referred to as interferon regulatory factor 8) (9)³. In murine bone marrow, transduction with a Bcr-abl expression vector decreases Icsbp expression *in vitro* and *in vivo* (11–13). Re-expression of Icsbp in Bcr-abl⁺ murine bone marrow decreases myeloproliferation and delays blast crisis *in vivo* (12). Mice with *IRF8* gene disruption phenocopy some aspects of CML, suggesting that Icsbp regulates target genes that are relevant to proliferation and survival of CML LSCs (14, 15).

Consistent with this hypothesis, we found that Icsbp represses *PTPN13*, the gene encoding Fap1. Search of publically available databases determined that Fap1 expression is increased in human CML³. We found previously that Bcr-abl-expressing murine myeloid progenitor cells exhibited Icsbp- and Fap1-dependent Fas resistance (3, 4). We also found that treatment of these cells with SLV peptide partly reversed Fas resistance (4).

In this study, we consider the possibility that Fap1 also contributes to the pathogenesis of CML by interacting with Apc. Apc assembles a multiprotein complex with Axin, Gsk3 β , and β catenin. Serine/threonine phosphorylation of β catenin by Gsk3 β facilitates β catenin ubiquitination and degradation by the proteasome (16, 17). This provides a potential mechanism for Fap1 to influence β catenin.

Molecular mechanisms that increase β catenin activity in CML are not well defined. Neither increased *CTNNB1* transcription nor Wnt signaling are found consistently in this disease (18). However, we determined previously that Icsbp influences β catenin activity by regulating the *GAS2* gene (13). Growth arrest-specific 2 (*Gas2*) is a calpain inhibitor, and β catenin is a calpain substrate (19). We found that increased *Gas2* expression in Bcr-abl⁺ myeloid progenitor cells contributed to stability and activity of β catenin (13).

In this study, we investigate the hypothesis that Fap1 also stabilizes β catenin in Bcr-abl⁺ cells by interfering with the Apc-Gsk3 β - β catenin complex. Fap1 might exert this effect by preventing assembly of the complex or by inactivating (dephosphorylating) a component protein. If this hypothesis is correct, therapeutic targeting of Fap1 might increase Fas sensitivity and decrease β catenin activity, impacting disease progression in CML.

EXPERIMENTAL PROCEDURES

Plasmids and Protein Expression Vectors—The Icsbp cDNA was obtained from Dr. Ben Zion-Levi (Technion, Haifa, Israel). The full-length cDNA was generated by PCR and subcloned into the mammalian expression vector pcDNA (Stratagene, La Jolla, CA) as described (20). The Bcr-abl (p210) cDNA in the MiGR1 retroviral vector was obtained from Dr. Ravi Bhatia (City of Hope National Medical Center, Duarte, CA) and was subcloned into the pcDNA expression vector. The cDNA for Gsk3 β was obtained from and subcloned into the pcDNAamp expression vector. A form of Gsk3 β with mutation of Tyr-216 to Asp was generated by PCR-based mutagenesis as described (21).

Plasmids and Reporter Constructs—The TopFlash and FopFlash reporter constructs were purchased from Millipore (Billerica, MA). TopFlash contains three copies of a consensus binding site for β catenin/Tcf-Lef linked to a minimal promoter and a luciferase reporter. FopFlash is a similar construct but with a mutation that abolishes β catenin/Tcf-Lef binding.

Myeloid Cell Line Culture—The human myelomonocytic leukemia cell line U937 (22) was obtained from Andrew Kraft (Hollings Cancer Center, Medical University of South Carolina, Charleston, SC). Cells were maintained as described (21).

Murine Bone Marrow Culture—Animal studies were performed according to a protocol approved by the Animal Care and Use Committees of Northwestern University and Jesse Brown Veterans Affairs Medical Center. Bone marrow mononuclear cells were obtained from the femurs of WT or Icsbp^{-/-} C57/BL6 mice. Sca1⁺ cells were separated using the Miltenyi magnetic bead system according to the instructions of the manufacturer (Miltenyi Biotechnology, Auburn, CA).

Bipotential GMPs were cultured (at a concentration of 2×10^5 cells/ml) for 48 h in DMEM supplemented with 10% fetal calf serum, 1% penicillin/streptomycin, 10 ng/ml murine granulocyte-monocyte colony stimulating factor (GM-CSF) (R&D Systems, Inc., Minneapolis, MN), and 10 ng/ml murine recombinant IL-3 (R&D Systems, Inc.). Cells were maintained in this medium for 48 h, and CD34⁺ cells were separated using the Miltenyi magnetic bead system, as above, for extraction of RNA or proteins.

Quantitative Real-time PCR for mRNA Expression—RNA was isolated using the TRIzol reagent according to the instructions of the manufacturer (Invitrogen). RNA was tested by denaturing gel electrophoresis to determine the integrity of the 18 S and 28 S ribosomal bands. Primers were designed with the software from Applied Biosystems, and real-time PCR was performed using SYBR Green according to the “standard curve” method. Results were normalized to 18 S to control for RNA abundance in various samples.

Stable Transfectant Myeloid Cell Lines—U937 cells were transfected by electroporation with a p210 Bcr-abl expression vector or empty vector control (Bcr-abl/pcDNAamp or pcDNAamp) plus a vector with a neomycin phosphotransferase cassette (pSR α) (30 μ g each). Stable pools of cells were selected in G418 (0.5 mg/ml).

Transient Transfections for Reporter Gene Assays—U937 cells (32×10^6 /ml) were transfected with various combinations of vectors to express p210 Bcr-abl or control (50 μ g), β catenin or control (50 μ g), Gsk3 β or Y216D-Gsk3 β , or control (50 μ g). Cells were cotransfected with the TopFlash reporter vector or FopFlash control (70 μ g) and a cytomegalo-virus/ β -galactosidase reporter (to control for transfection efficiency). Transfectants were assayed for luciferase expression using a luciferase assay system according to the instructions of the manufacturer (Promega, Madison, WI). Assays for β -galactosidase expression were performed as described previously (23, 24).

Western Blot Analyses of Lysate Proteins—U937 or murine bone marrow cells were lysed by boiling in $2 \times$ SDS sample buffer. Lysate proteins (50 μ g) were separated by SDS-PAGE (8% acrylamide) and transferred to nitrocellulose according to standard techniques. Western blot analyses were serially probed with antibodies as described (3, 4). Each experiment was repeated at least three times with different batches of lysate proteins. A representative blot is shown. The band intensity on the blots was determined using UN-SCAN-IT software, and results were normalized for the band intensity of the loading control.

Immunoprecipitation and Western Blot Analyses—Lysate proteins from U937 or murine bone marrow cells were immunoprecipitated under denaturing conditions with antibody to Apc (Santa Cruz Biotechnology, Santa Cruz, CA). Precipitated proteins were collected with Staph protein A-Sepharose, separated by SDS-PAGE, and transferred to nitrocellulose as above. Western blot analyses were probed with antibodies as described. Each experiment was repeated at least three times with different batches of lysate proteins. A representative blot is shown.

In Vitro Protein Translation and PTP Assays—*In vitro*-translated, ³⁵S-labeled Gsk3 β was generated in rabbit reticulocyte lysate as described previously (21). For PTP assays, *in vitro*-translated protein was incubated for 30 min at 30° with recombinant Fap1 or control buffer. Proteins were diluted in radioimmune precipitation assay buffer, precipitated with antibody to phospho-Tyr-216-Gsk3 β , and then immunoprecipitates were collected with staphylococcus protein A-Sepharose. Proteins were separated by SDS-PAGE and identified by autoradiography of immunoprecipitates. 1/10 input protein is included as a loading control and to demonstrate that Fap1 does not degrade Gsk3 β .

Bcr-abl Increases β catenin via Fap1

Cell Proliferation Assays—Murine bone marrow cells were transduced with a retroviral vector to Bcr-abl or empty MiGR1 vector control and cultured in GM-CSF (10 ng/ml), IL3 (5 ng/ml), or stem cell factor (100 ng/ml); deprived of cytokines for 24 h (cultured in DMEM supplemented with 10% FCS only); and stimulated for 24 h with a dose titration of GM-CSF (0.02 to 20 ng/ml + 5 ng/ml of IL3). Cells were treated with SLV Fap1-blocking peptide or VLS control peptide, and cell proliferation was determined by incorporation of ^3H -thymidine as described (13).

Confocal Fluorescent Microscopy—Cells were fixed with 4% w/v paraformaldehyde, permeabilized with 100% methanol at -20°C for 10 min, and incubated with primary antibody overnight at 4°C . Cy3-conjugated secondary antibody (Jackson ImmunoResearch Laboratories, Inc.) was added for 2 h at room temperature. Slides were mounted with ProLong Gold anti-fade reagent with DAPI (Invitrogen). Fluorescence signals were acquired using a Zeiss LSM 510 laser-scanning confocal microscope.

Statistical Analysis—Statistical significance was determined by Student's *t* test and analysis of variance methods using the SigmaPlot and SigmaStat software.

RESULTS

Blocking the Interaction between Fap1 and Apc Increases Gsk3 β Activity and Decreases β Catenin—We found previously that treatment of myeloid leukemia cell lines with SLV peptide resulted in decreased Fap1/Fas interaction, increased Fas-tyrosine phosphorylation, and sensitivity to Fas-induced apoptosis (effects not observed with VLS control peptide) (3, 4). In this studies, we tested the ability of SLV peptide to decrease interaction of Fap1 with Apc. For these experiments, U937 myeloid leukemia cells were treated with SLV peptide or VLS control. Cell lysates were immunoprecipitated with an antibody to Apc, and immunoprecipitates were analyzed by Western blot analysis.

We found abundant coprecipitation of Fap1 with Apc in control lysates, but this interaction was decreased by SLV peptide treatment (Fig. 1A). This was not unexpected because Fas and Apc interact with Fap1 through the same Fap1-PDZ domain. Consistent with this, we found that a tripeptide representing the Apc C terminus (threonine-serine-valine) equivalently disrupted Fap1/Apc interaction *in vitro* (not shown). Treatment with SLV peptide did not alter expression of Fap1 or Apc proteins (Fig. 1A).

We hypothesize that interaction of Fap1 with Apc decreased serine/threonine phosphorylation of β catenin by Gsk3 β , thereby increasing β catenin protein stability. To investigate this, U937 cells were treated with Fap1-blocking SLV peptide or valine-leucine-serine control peptide and lysate proteins were analyzed by Western blot analysis. We found that treatment with SLV peptide decreased total β catenin protein but increased phosphorylation of serine/threonine residues involved in degradation (Fig. 1B). This could be because Fap1 disrupted the Apc-Gsk3 β - β catenin complex or because Fap1 inactivated (dephosphorylates) Gsk3 β . Consistent with the second hypothesis, we found that SLV peptide increased tyrosine phosphorylation of Gsk3 β in U937 cells.

These data suggest that Fap1, Apc, and Gsk3 β are present in a single protein complex. To investigate this, lysate proteins from U937 cells were first immunoprecipitated with an Apc

FIGURE 1. Fap1 influences Gsk3 β activity, β catenin protein expression, and serine/threonine phosphorylation of β catenin in myeloid cell lines.

A, treatment of U937 myeloid leukemia cells with SLV peptide disrupts interaction between Fap1 and Fas. U937 cells were treated with Fap1-blocking SLV peptide or control VLS peptide. Cell lysates were immunoprecipitated (IP) under non-denaturing conditions with an antibody to Apc or irrelevant control antibody. Immunoprecipitates were analyzed by Western blot analysis for coprecipitation of Fap1 with Apc. Non-immunoprecipitated lysates were analyzed as a loading control. **B**, treatment with of U937 myeloid leukemia cells with SLV peptide increases tyrosine phosphorylation of Gsk3 β , decreases total β catenin protein, and increases serine/threonine phosphorylated β catenin. U937 cells were treated with Fap1-blocking SLV peptide or control VLS peptide. Cell lysates were analyzed by Western blot analyses serially probed with antibodies to total β catenin, β catenin phosphorylated on Ser-33/37 or Thr-47, Gsk3 β , Gsk3 β phosphorylated on Tyr-216, or Gapdh (as a loading control). **C**, Fap1, Apc, and Gsk3 β are present in a single protein complex. U937 cell lysate proteins were immunoprecipitated under non-denaturing conditions with an Apc antibody or irrelevant control antibody. Immunoprecipitates were recovered, and a second round of immunoprecipitation was performed with a Fap1 antibody or irrelevant control antibody. Immunoprecipitates were separated by SDS-PAGE, and Western blot analyses (WB) were probed with antibodies to Apc, Fap1, and Gsk3 β . Non-precipitated proteins were used as a loading control.

antibody, collected with *Staphylococcus* protein A-Sepharose, and then eluted proteins were precipitated with an antibody to Fap1. Western blot analyses of the immunoprecipitates demonstrated Apc, Fap1, and Gsk3 β in the double immunoprecipitation eluate (Fig. 1C). This suggests the existence of a trimolecular protein complex that contains all three proteins rather than sets of heterodimers.

Fap1 Influences β Catenin Activity in Icsbp $^{-/-}$ Myeloid Progenitor Cells—We found previously that Fap1-expression was relatively increased in myeloid progenitor cells from Icsbp $^{-/-}$ mice in comparison to wild-type mice (3). Therefore, we investigated the impact of Fap1 blocking peptide on Gsk3 β activity and β catenin serine/threonine phosphorylation in these cells. For these studies, mononuclear cells were isolated from the bone marrow of WT or Icsbp $^{-/-}$ mice; cultured in GM-CSF, IL3, and Scf; and treated with Fap1-blocking SLV peptide or VLS control. Lysate proteins from CD34 $^{+}$ cells were analyzed by Western blot analysis.

We found that total β catenin protein was increased in Icsbp $^{-/-}$ cells in comparison to WT cells, consistent with our previous studies ($\sim 35\%$ increase by densitometry of the bands on Western blot analysis) (13). Treatment of Icsbp $^{-/-}$ cells with SLV peptide decreased β catenin protein (Fig. 2A, $\sim 42\%$ by densitometry of bands on Western blot analysis). Conversely,

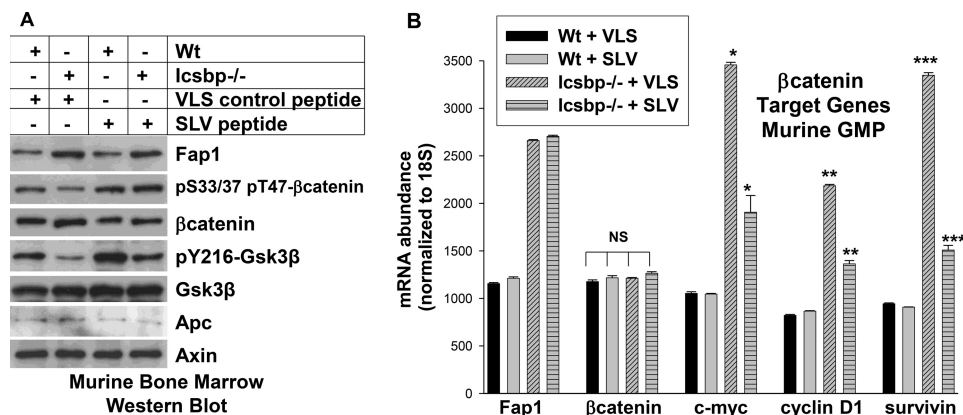

FIGURE 2. Fap1 influences tyrosine phosphorylation of Gsk3 β , β catenin protein expression, and serine/threonine phosphorylation of β catenin in an Icsbp-dependent manner. A, treatment of primary Icsbp^{-/-} murine myeloid progenitor cells with Fap1-blocking peptide increases tyrosine phosphorylation of Gsk3 β , decreases β catenin protein, and increases β catenin serine/threonine phosphorylation. Bone marrow mononuclear cells from WT or Icsbp^{-/-} mice were cultured in IL3, GM-CSF, and Scf, and CD34⁺ cells were separated (considered GMP conditions). Cells were treated with Fap1-blocking SLV peptide or control VLS peptide, and lysates were analyzed by Western blot analysis. Blots were serially probed with antibodies to Fap1, total and serine/threonine phosphorylated β catenin, total and Tyr-216 phosphorylated Gsk3 β , Apc, and Axin (as a loading control). B, treatment of primary Icsbp^{-/-} murine myeloid progenitor cells with SLV peptide decreases β catenin target gene expression. The cells described above were also analyzed for expression of mRNA representing Fap1, β catenin, and β catenin target genes (c-myc, cyclinD1, survivin) by real-time PCR. Statistically significant differences in mRNA abundance with SLV versus VLS peptide are indicated by *, **, or ***. NS, not significant. *, **, and *** represent statistically significant differences.

serine/threonine phosphorylation of β catenin was less in Icsbp^{-/-} cells in comparison to WT, and was increased by SLV peptide treatment. Activity (tyrosine phosphorylation) of Gsk3 β was less in Icsbp^{-/-} myeloid progenitor cells in comparison to WT but was increased by Fap1-blocking peptide (Fig. 2A). Total Gsk3 β protein was equivalent under these four conditions.

We also investigated the impact of Fap1-blocking peptide on expression of β catenin target genes, including c-myc, cyclinD1, and survivin. For these experiments, WT or Icsbp^{-/-} cells were treated with SLV peptide or VLS control and analyzed by real-time PCR for Fap1, β catenin, and β catenin target genes. We found increased Fap1 mRNA expression in Icsbp^{-/-} myeloid progenitor cells in comparison to WT cells (as in Ref. 3). Fap1 mRNA was not altered by treatment with SLV peptide, consistent with protein expression levels (Fig. 2B). In contrast, β catenin mRNA was equivalent in Icsbp^{-/-} and WT cells. We found increased expression of β catenin target genes in Icsbp^{-/-} cells relative to WT cells (Fig. 2B) (13). Increased β catenin target gene expression was partly reversed by treating Icsbp^{-/-} cells with SLV peptide, indicating partial Fap1 dependence for this effect.

In control experiments, treatment with SLV was compared with other Fap1 blocking peptides, including TSV (C-terminal sequence from Apc) or cysteine-leucine-glutamine (murine Fap1 C-terminal sequence) (25). We found that treatment with these peptides had the same effect as SLV peptide but their scrambled control peptides did not. CLE peptide competed more efficiently with Fap1 for either Fas or Apc in studies with murine bone marrow cells by coimmunoprecipitation and Western blot analysis (~5-fold less peptide required, data not shown). This is consistent with a previously documented higher efficiency of interaction between murine Fap1 and murine Fas in comparison to interaction between murine Fap1 and human Fas (2).

Fap1 Influences β Catenin Activity in Bcr-abl⁺ Myeloid Leukemia Cells—In previous studies, we identified an Icsbp-dependent increase in expression of Fap1 and Gas2 in Bcr-abl-trans-

duced myeloid cell lines (4, 13). We found that increased β catenin protein and activity (but not mRNA) in Bcr-abl⁺ cells was partly due to inhibition of calpain activity by Gas2 (13). In this study, we investigate the contribution of Fap1 to increased β catenin in Bcr-abl⁺ cells. U937 myeloid leukemia cells were stably transfected with a vector to express Bcr-abl or empty control vector. U937 is a monocytoid leukemia line that does not have t(9;22) (22).

Bcr-abl⁺ and control cells were treated with Fap1-blocking SLV peptide or VLS control and cell lysates were analyzed by Western blot. We found relatively increased expression of Fap1 and β catenin in Bcr-abl⁺ cells in comparison to control cells, as in our previous studies (Fig. 3A) (4, 13). This was associated with decreased serine/threonine phosphorylation of β catenin, and decreased tyrosine phosphorylation of Gsk3 β . Consistent with our hypothesis, SLV treatment decreased total β catenin protein in Bcr-abl⁺ cells, but increased serine/threonine phosphorylated β catenin and tyrosine phosphorylated (active) Gsk3 β (Fig. 3A). Total β catenin and tyrosine phosphorylated Gsk3 β were approximately equivalent in SLV peptide treated Bcr-abl⁺ cells and in VLS treated control U937 cells.

To determine the relative contributions of Gas2 and Fap1 to β catenin protein expression, we cotransfected Bcr-abl⁺ U937 cells with a vector to express a dominant negative Gas2 (DN-Gas2) or empty control vector. Cells were treated with SLV peptide or VLS control, and lysates were analyzed for β catenin by Western blot analysis. We found that treatment with SLV peptide decreased β catenin protein more efficiently than expression of DN-Gas2 (Fig. 3B, decrease of 72% versus 51% by densitometry of Western blot analyses). We also found that SLV peptide cooperated with DN-Gas2 to further decrease β catenin (90% by densitometry of Western blot analyses). This suggests that Fap1 and Gas2 influence β catenin through complementary mechanisms.

To investigate whether increased serine/threonine phosphorylation of β catenin protein in SLV treated increases degradation by the proteasome, we treated some Bcr-abl⁺ U937 cells

Bcr-abl Increases β catenin via Fap1

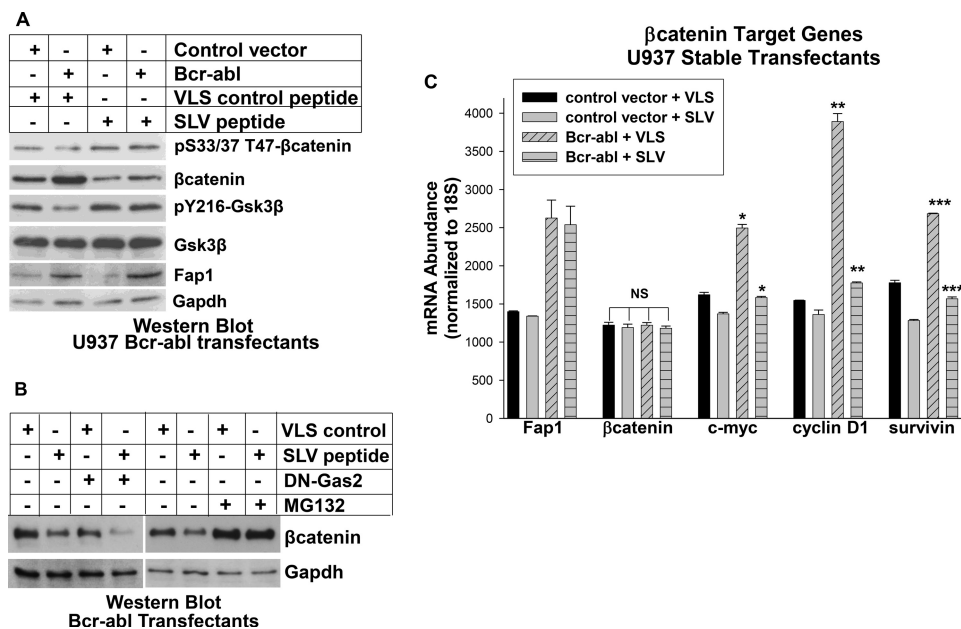

FIGURE 3. Bcr-abl influences β catenin expression and activity in a Fap1-dependent manner in myeloid leukemia cells. *A*, treatment of Bcr-abl⁺ U937 cells with SLV peptide increases tyrosine phosphorylation of Gsk3 β , decreases β catenin protein, and increases serine/threonine phosphorylation of β catenin. U937 cells were stably transfected with a Bcr-abl expression vector or empty control vector and treated with Fap1-blocking SLV peptide or control VLS peptide. Cell lysates were analyzed by Western blot analyses serially probed with antibodies to Fap1, total and serine/threonine phosphorylated β catenin, total and Tyr-216 phosphorylated Gsk3 β , Apc, and Gapdh (loading control). *B*, Fap1-blocking SLV peptide decreases β catenin protein in Bcr-abl⁺ U937 cells in a manner that was augmented by dominant negative Gas2 but antagonized by the proteasome inhibitor MG132. Bcr-abl⁺ U937 stable transfectants were cotransfected with a vector to express dominant negative Gas2 (DN-Gas2) or vector control or treated with MG132. The effect of treatment with SLV peptide or VLS control was determined by Western blot analysis for β catenin. Blots were probed with an antibody to Gapdh as a loading control. *C*, treatment of Bcr-abl⁺ U937 cells with SLV peptide decreases β catenin target gene expression. The cells described in *A* were also analyzed for expression of mRNA representing Fap1, β catenin, and β catenin target genes (c-myc, cyclinD1, survivin) by real-time PCR. Statistically significant differences in mRNA abundance with SLV versus VLS peptide are indicated by *, **, or ***. NS, not significant. *, **, and *** represent statistically significant differences.

MG132 (a proteasome inhibitor). We found an increase in β catenin protein in Mg132-treated cells that was not altered by treatment with SLV peptide (Fig. 3*B*, decrease of 61% versus 56% without MG132 by densitometry of Western blot analyses).

We investigated β catenin activity in Bcr-abl⁺ cells by analyzing the expression of β catenin target genes. We found increased expression of c-myc, cyclinD1, and survivin in Bcr-abl⁺ transfectants in comparison to control cells, and this was partly reversed by SLV peptide treatment (Fig. 3*C*). In control experiments, we determined that mRNA expression for Fap1, but not β catenin, was increased by Bcr-abl⁺ expression in U937 cells, consistent with our previous studies (4, 13). Fap1 expression was not altered by treatment with SLV peptide (Fig. 3*C*).

Three independent stable transfectants pools were selected for each construct, and Bcr-abl transgene expression was confirmed by real-time PCR and Western blot analysis (data not shown, as in Refs. 4, 13). Western blot analyses are representative studies, and real-time PCR results represent data from all transfectant pools.

Fap1 Influences β Catenin Activity in Bcr-abl⁺ Myeloid Progenitor Cells—U937 is a transformed cell line with abnormalities in cell proliferation and survival prior to introduction of the Bcr-abl oncogene. To study Bcr-abl in the absence of other transforming events, we transduced primary murine bone marrow cells with a Bcr-abl retroviral expression vector or with empty control vector. Transduced cells were cultured in GM-CSF, IL3, and Scf, and CD34⁺ cells were isolated (considered GMP conditions for these studies) (3, 4, 13). Cells were treated with SLV peptide or VLS control. Previous studies by other investigators determined that a

Bcr-abl⁺ GMP with increased β catenin activity functions as the leukemia stem cell in chronic-phase CML (8).

We found increased Fap1 and β catenin protein and decreased serine/threonine phosphorylated β catenin in Bcr-abl⁺ myeloid progenitor cells in comparison with control cells (Fig. 4*A*). The increase in Fap1 protein was not altered by treatment with SLV peptide. In contrast, the increase in β catenin protein in Bcr-abl⁺ cells was reversed by SLV peptide (58% decrease by densitometry of bands on Western blot analysis), and β catenin serine/threonine phosphorylation was increased. Expression and serine/threonine phosphorylation of β catenin in SLV-treated Bcr-abl⁺ myeloid progenitor cells was equivalent to expression and serine/threonine phosphorylation in control vector-transduced, VLS-treated cells (Fig. 4*A*). Tyrosine-phosphorylated (but not total) Gsk3 β was less in Bcr-abl-transduced cells in comparison with control cells, and this was reversed by treatment with SLV peptide.

These lysates were also immunoprecipitated with an Apc antibody and analyzed for association of Fap1 with Apc, Axin, Gsk3 β , and β catenin by Western blot analysis. We found increased Fap1 in Apc coimmunoprecipitates from Bcr-abl-transduced cells in comparison with control cells (Fig. 4*A*). We also found increased total β catenin protein in Apc coimmunoprecipitates from Bcr-abl⁺ cells but decreased serine/threonine phosphorylated β catenin. We also found that Gsk3 β tyrosine phosphorylation was less in Apc coimmunoprecipitates from Bcr-abl⁺ cells in comparison with control cells. Consistent with our hypothesis, these Bcr-abl-related differences were reversed by treatment with SLV peptide (Fig. 4*A*).

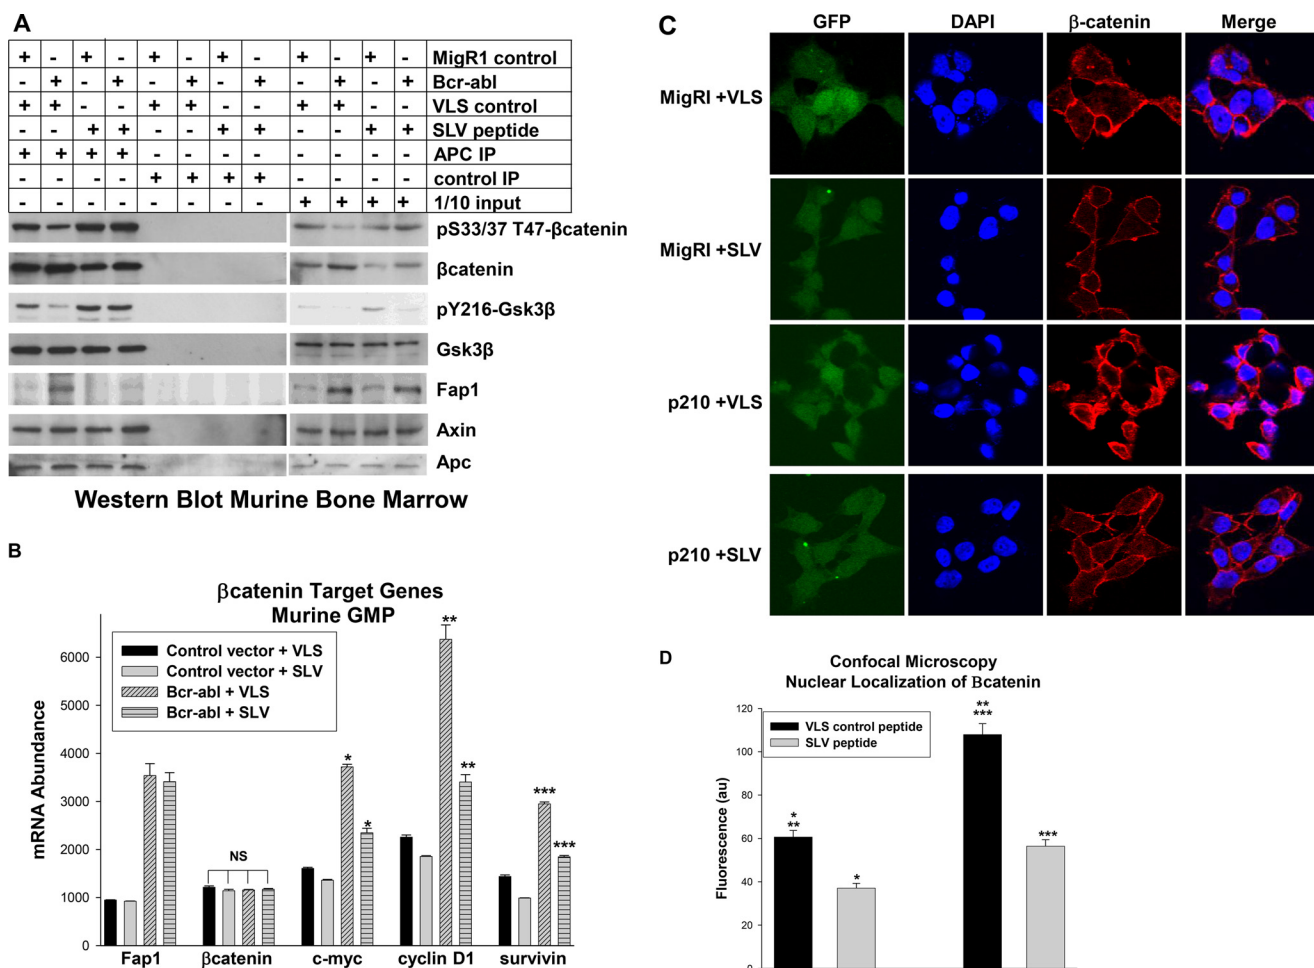

FIGURE 4. *Bcr-abl* influences β catenin expression and activity in a *Fap1*-dependent manner in primary murine myeloid progenitor cells. *A*, treatment of *Bcr-abl*⁺ primary murine myeloid progenitor cells with SLV peptide decreases *Fap1*/*Apc* interaction, decreases tyrosine phosphorylation of *Gsk3 β* , decreases β catenin protein, and increases serine/threonine phosphorylation of β catenin. Bone marrow mononuclear cells from WT mice were transduced with a *Bcr-abl*-expression vector or empty control vector. The GMP population was cultured (as described above) and treated (IP) with *Fap1*-blocking SLV peptide or control VLS peptide. Cell lysates were immunoprecipitated with an antibody to *Apc* or irrelevant control antibody, and immunoprecipitates were analyzed by Western blot analysis. Non-precipitated lysate was used to control for total protein abundance. Blots were serially probed with antibodies to total and serine/threonine phosphorylated β catenin, total and Tyr-216 phosphorylated *Gsk3 β* , *Fap1*, *Apc*, and *Axin*. *B*, treatment of *Bcr-abl*⁺ primary murine myeloid progenitor cells with SLV peptide decreases β catenin-target-gene expression. The cells described above were also analyzed for abundance of mRNA representing *Fap1*, β catenin, and β catenin target genes (*c-myc*, *cyclinD1*, *survivin*) by real-time PCR. Statistically significant differences in mRNA abundance with SLV versus VLS peptide are indicated by *, **, or ***. NS, not significant. *C*, SLV peptide treatment decreases nuclear β catenin in *Bcr-abl*⁺ murine myeloid progenitor cells. Murine bone marrow cells were transduced with a *Bcr-abl*-expression vector or empty *MigR1* control vector and treated with *Fap1*-blocking SLV peptide or VLS control. Cells were analyzed by confocal microscopy for nuclear localization of β catenin. Transduced cells are green (green fluorescent protein label in vector), nuclei are indicated in blue (DAPI stain), β catenin is shown in red (Cy3-labeled secondary antibody), and purple indicates merged DAPI + Cy3 signals. *D*, nuclear β catenin is significantly decreased by SLV peptide treatment of *Bcr-abl*⁺ murine bone marrow cells. The cells described above were analyzed for fluorescent intensity of the merged signal. At least 30 cells were counted in three fields for each sample. Statistically significant differences are indicated by *, **, or ***.

We used these transduced cells to investigate the effects of *Bcr-abl* and *Fap1*-blocking peptide on expression of β catenin target genes. We found increased expression of *c-myc*, *cyclinD1*, and *survivin* in *Bcr-abl*-transduced cells relative to control cells, consistent with our previous studies (13). We also found that treatment of these cells with SLV peptide partly reversed the increase in β catenin target gene expression in *Bcr-abl*⁺ cells (Fig. 4*B*). As in the studies above, mRNA expression of *Fap1*, but not β catenin, was increased in *Bcr-abl*⁺ cells versus control cells, and this was not influenced by treatment with SLV peptide (Fig. 4*B*).

These studies were repeated in at least two independent transduction experiments, and *Bcr-abl*-transgene expression was confirmed by real-time PCR and Western blot analysis (data not shown). Representative Western blot analyses are

shown, and real-time PCR represents data from all transduction experiments.

We also used these cells to study the role of *Fap1* blockade on β catenin nuclear localization. For these experiments, transduction was determined by expression of green fluorescent protein by the *MigR1* vector used to express *Bcr-abl* (versus control *MigR1*). Cells were stained with antibodies to colocalize β catenin with nuclear structures. Transduced murine GMP were studied after treatment with *Fap1*-blocking SLV peptide or VLS control. We found that nuclear β catenin was significantly increased in *Bcr-abl*-transduced cells in comparison to control vector-transduced cells (Fig. 4*C*). We also found that SLV peptide significantly decreased nuclear β catenin abundance in *Bcr-abl*-transduced cells (Fig. 4*C*). These data were

Bcr-abl Increases β catenin via Fap1

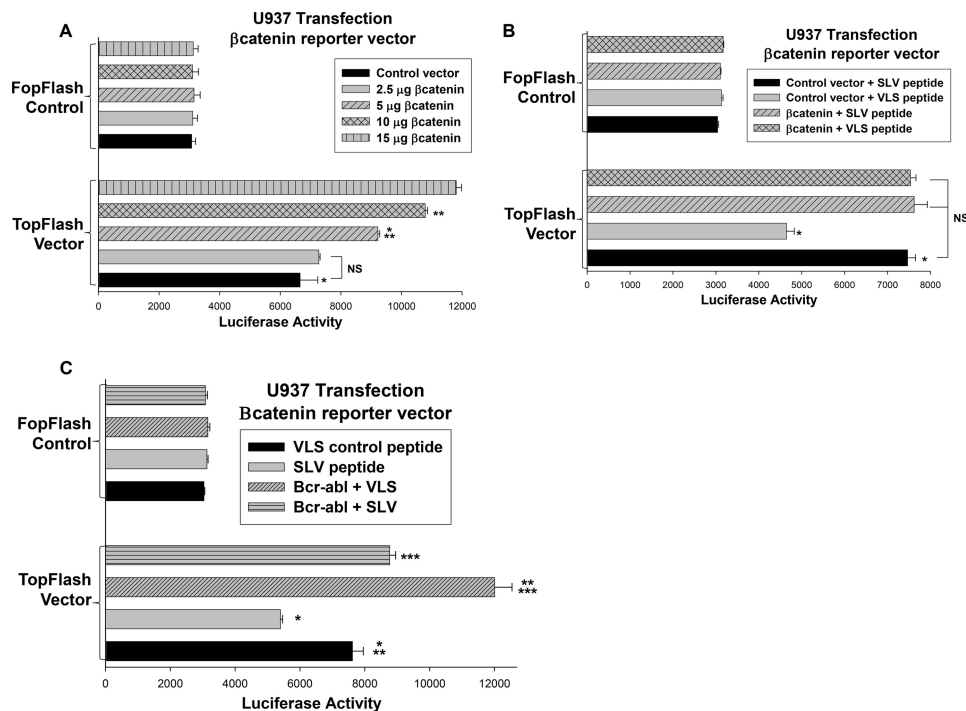

FIGURE 5. Fap1 contributes to β catenin-induced transcriptional activation in Bcr-abl⁺ cells. *A*, β catenin-overexpression in U937 cells activates a reporter construct with a β catenin/Tcf binding consensus sequence in a dose-dependent manner. U937 cells were cotransfected with a construct with a β catenin/Tcf-binding consensus sequence linked to a minimal promoter and reporter (TopFlash) or a construct with mutation of the β catenin binding site (FopFlash) and a vector to express β catenin (or empty control vector). Reporter activity was determined and statistically significant differences are indicated by * and **. NS, not significant. *B*, decreased activity of a β catenin-binding reporter construct in SLV peptide-treated U937 transfectants is reversed by β catenin overexpression. U937 cells were cotransfected with TopFlash or FopFlash (control) reporter constructs and a vector to express β catenin (2.5 μ g, the lowest dose that does not increase TopFlash activity above background). Transfectants were treated with Fap1-blocking SLV peptide or control VLS peptide, and reporter gene activity was determined. Statistically significant differences with SLV versus VLS peptide are indicated by *. *C*, treatment of U937 transfectants with SLV peptide blocks Bcr-abl-induced activation of a β catenin-binding reporter construct. U937 cells were cotransfected with TopFlash or control FopFlash reporter vector and a vector to express Bcr-abl (or control vector). Transfectants were treated with Fap1-blocking SLV peptide or control VLS peptide, and reporter gene activity was determined. Statistically significant differences in TopFlash reporter activity are indicated by *, **, or ***.

quantified by measuring the fluorescent intensity of the nuclear colocalization signal for 30 cells in three different high-power fields (Fig. 4D).

Fap1 Influences β Catenin-induced Transactivation in Bcr-abl⁺ Myeloid Leukemia Cells—In the studies above, we used β catenin target gene expression as a measure of β catenin activity. β Catenin activity is more directly measured by determining activation of an artificial promoter/reporter construct with a β catenin/Tcf-binding consensus sequence (26). We used this construct (referred to as TopFlash) and a non- β catenin binding control construct (FopFlash) in U937 transfection studies. For initial experiments, cells were cotransfected with a dose titration of a β catenin expression vector. We found that TopFlash reporter activity increased in a β catenin dose-dependent manner but that control FopFlash activity did not (Fig. 5A). The goal of this study was to identify the plasmid doses that result in maximal or minimal effects of overexpressing β catenin in these cells.

Using these results, we cotransfected U937 cells with a vector to express TopFlash or FopFlash and a vector to express β catenin (2.5 μ g) or empty control vector. Transfectants were treated with Fap1-blocking SLV peptide or control peptide, and reporter activity was determined. We found that SLV peptide significantly decreased activity of the TopFlash reporter vector in control transfectants ($p < 0.01$, $n = 4$) (Fig. 5B). In contrast, SLV peptide had a minimal effect on this reporter construct in

cells that were cotransfected with increasing amounts of a β catenin expression vector ($p = 0.8$, $n = 4$).

We also tested the effect of blocking Fap1 on β catenin activity in Bcr-abl-expressing transfectants. U937 cells were cotransfected with the TopFlash or FopFlash reporter vector and a vector to express Bcr-abl. Cells were treated with SLV or VLS (control) peptide, and reporter activity was determined. We found that TopFlash reporter activity was significantly greater in Bcr-abl-transfectants in comparison with control transfectants ($p < 0.01$, $n = 4$) (Fig. 5C). SLV peptide significantly decreased TopFlash activity in Bcr-abl-expressing transfectants ($p < 0.03$, $n = 4$). These studies suggest a Fap1-dependent increase in β catenin activity in Bcr-abl-expressing cells. In control studies, we found that FopFlash reporter activity was not significantly influenced by expression of β catenin, Bcr-abl, or treatment with SLV or VLS peptides.

Gsk3 β Mediates a Fap1-dependent Increase in β Catenin Activity in Bcr-abl⁺ Cells—The studies above support the hypothesis that Apc recruits Fap1 to the Apc/Gsk3 β / β catenin complex and leads to inactivation of Gsk3 β . Because Fap1 is a PTP and Gsk3 β is activated by tyrosine phosphorylation, we considered the possibility that Gsk3 β is a Fap1 substrate. We used an *in vitro* PTP assay with Gsk3 β expressed in rabbit reticulocyte lysate to investigate this hypothesis. We first confirmed that *in vitro*-translated Gsk3 β is phosphorylated on Tyr-

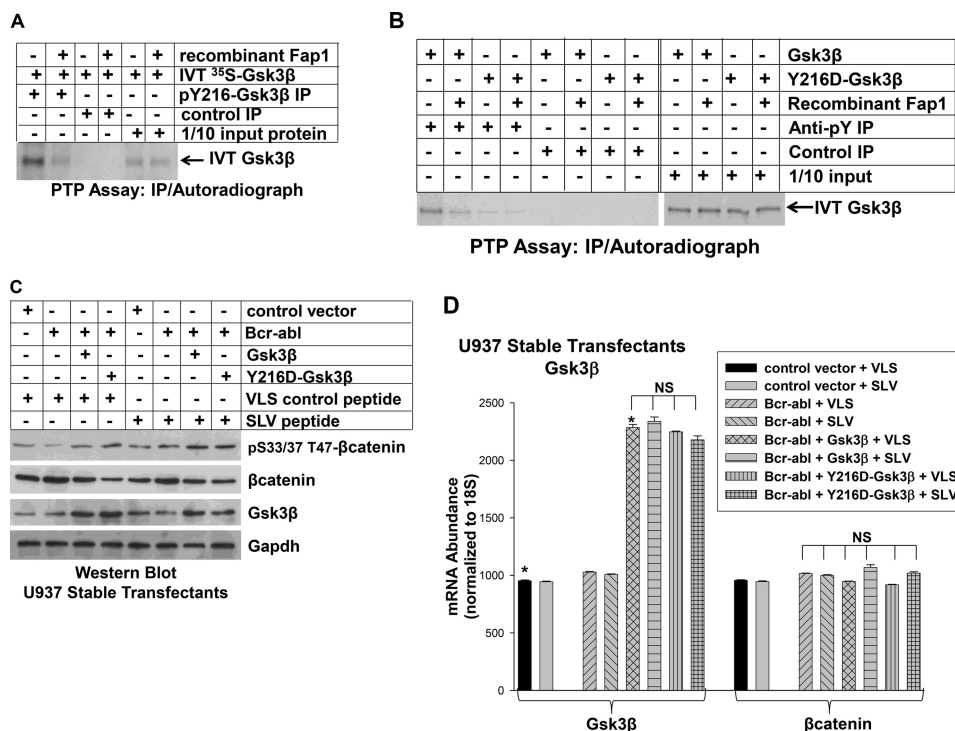

FIGURE 6. Fap1 decreases activity and tyrosine phosphorylation of Gsk3 β . *A*, recombinant Fap1 dephosphorylates *in vitro*-translated (IVT) Gsk3 β . Gsk3 β was translated *in vitro* in rabbit reticulocyte lysate (in the presence of [³⁵S]methionine) and incubated with recombinant Fap1 or with buffer control. Proteins were immunoprecipitated (IP) with an antibody to phospho-Tyr-216-Gsk3 β or irrelevant control antibody, separated by SDS-PAGE, and identified by autoradiography. 1/10 input (non-immunoprecipitated) Gsk3 β was used as a loading control. *B*, recombinant Fap1 dephosphorylates Gsk3 β primarily at Tyr-216. Gsk3 β or a form of Gsk3 β with mutation of Tyr-216 (Y216D) were *in vitro*-translated in rabbit reticulocyte lysate as above. Proteins were incubated with recombinant Fap1 or buffer control and immunoprecipitated with an antibody to phospho-tyrosine residues (4G10) or with irrelevant control antibody. Immunoprecipitates were separated by SDS-PAGE and detected by autoradiography. *C*, expression of constitutively active Gsk3 β (Y216D) in Bcr-abl⁺ U937 cells decreases β catenin protein and increases serine/threonine phosphorylation of β catenin in a manner that is not influenced by SLV peptide. U937 cells were cotransfected with a Bcr-abl expression vector and a vector to express Y216D-Gsk3 β or WT Gsk3 β (or empty control vector). Cells were treated with Fap1-blocking SLV peptide or VLS control peptide and lysates analyzed by Western blot analysis. Blots were serially probed with antibodies to total and serine/threonine phosphorylated β catenin, Gsk3 β , and Gapdh (as a loading control). *D*, expression of constitutively active Gsk3 β (Y216D) in Bcr-abl⁺ U937 cells does not alter expression of β catenin mRNA. The stably transfected U937 cells described above were also analyzed for mRNA expression of Gsk3 β and β catenin by real-time PCR. Statistically significant differences are indicated by *. NS, not significant.

216 by immunoprecipitation with a phospho-Tyr-216-Gsk3 β -specific antibody (Fig. 6A). This residue is the key to Gsk3 β activity (27).

We incubated *in vitro*-translated Gsk3 β with recombinant Fap1 or buffer control under standard PTP assay conditions (as in Ref. 21). Following incubation, proteins were immunoprecipitated with an antibody to phospho-Tyr-216-Gsk3 β , separated by SDS-PAGE, and identified by autoradiography. We found that incubation with recombinant Fap1 decreased phospho-Tyr-216 of Gsk3 β but did not alter total Gsk3 β (Fig. 6A).

To investigate the possibility that Fap1 dephosphorylated other Tyr residues in Gsk3 β , we generated *in vitro*-translated Gsk3 β with mutation of Tyr-216 to an amino acid that cannot be phosphorylated (Y216D-Gsk3 β). WT and Y216D-Gsk3 β were treated with recombinant Fap1 (or control, as described above), and lysates were immunoprecipitated with an antibody that recognizes phospho-tyrosine residues (4G10). Although the amounts of input protein were equal, far less Y216F-Gsk3 β was immunoprecipitated by anti-phospho-tyrosine antibody in comparison with WT Gsk3 β (Fig. 6B).

After Fap1 treatment, the amount of WT Gsk3 β that immunoprecipitated with anti-phospho-tyrosine antibody decreased (Fig. 6B, as in A). However, Fap1 treatment resulted in little change in the amount of Y216D-Gsk3 β that was immunopre-

cipitated by anti-phospho-tyrosine antibody. The amount of precipitating Fap1-treated WT Gsk3 β and Y216D-Gsk3 β were similar to each other and to untreated Y216D-Gsk3 β (Fig. 6B).

If Fap1 influences β catenin protein stability and activity by inactivating (dephosphorylating) Gsk3 β , expressing a constitutively active form of Gsk3 β will increase serine/threonine phosphorylation of β catenin and destabilize β catenin protein in Bcr-abl⁺ cells. To test this hypothesis, we used Y216D-Gsk3 β because Asp is a charged amino acid that mimics phospho-tyrosine residues but is not influenced by PTP activity. If our hypothesis is correct, treatment of Bcr-abl⁺ Y216D-Gsk3 β -expressing cells with SLV peptide will not influence β catenin serine/threonine phosphorylation or stability.

We generated U937 stable transfectants with a vectors to coexpress Bcr-abl and WT Gsk3 β or Y216D-Gsk3 β (or empty vector control). Cells were treated with SLV peptide or control VLS peptide, and lysate proteins were analyzed by Western blot analysis. We found that expression of Y216D-Gsk3 β decreased β catenin protein in Bcr-abl⁺ cells in a manner that was not influenced by SLV peptide (Fig. 6C, decrease of 43% versus 39% by densitometry of bands on Western blot analyses). In contrast, SLV treatment further decreased β catenin expression (decrease of 32% by densitometry of bands on Western blot analyses) and increased serine/threonine phosphorylation of

Bcr-abl Increases β catenin via Fap1

FIGURE 7. Constitutive activation of Gsk3 β bypasses Fap1. A, expression of Y216D-Gsk3 β in U937 cells decreases activity of a β catenin-binding reporter construct more efficiently than WT Gsk3 β . U937 cells were cotransfected with the β catenin-activated TopFlash reporter vector or FopFlash control vector and a dose titration of vectors to overexpress WT or Y216D-Gsk3 β (or control vector). Statistically significant differences in reporter expression are indicated by *, **, ***, #, ##, or ###. B, Y216D-Gsk3 β blocks Bcr-abl-induced activation of a β catenin-binding reporter construct in U937 transfectants in a manner that is not influenced by SLV peptide. U937 cells were cotransfected with the TopFlash or control FopFlash reporter vector, a vector to express Bcr-abl (or control vector), and a vector to express WT or Y216D-Gsk3 β (or vector control). Transfectants were treated with Fap1-blocking SLV peptide or control VLS peptide, and reporter gene activity was determined. Statistically significant differences are indicated by *, **, ***, or #. NS, not significant.

β catenin in control cells. Expression of β catenin mRNA was not altered by overexpression of either form of Gsk3 β or by treatment with SLV peptide (Fig. 6D).

We next determined whether Y216D-Gsk3 β influenced β catenin activity. For these studies, U937 cells were cotransfected with the TopFlash β catenin-binding reporter vector or FopFlash control vector and vectors to express dose titrations of WT Gsk3 β or Y216D-Gsk3 β . We found that both WT and Y216D-Gsk3 β significantly decreased TopFlash activity in a dose dependent manner (Fig. 7A) ($p < 0.01$, $n = 4$). We also found that the effect of Y216D-Gsk3 β was significantly greater than the effect of the wild-type Gsk3 β at most doses ($p < 0.005$, $n = 3$ for transfectants with 20 or 50 μ g of vector to express WT or Y216D-Gsk3 β).

We also investigated the effect of constitutive Gsk3 β activation on Fap1-dependent β catenin activity. U937 cells were cotransfected with the TopFlash or control FopFlash reporter vector, a vector to express WT or Y216D-Gsk3 β (or control vector), and a vector to express Bcr-abl (or control vector). Transfectants were treated with Fap1-blocking SLV peptide or VLS control. We found that SLV peptide significantly

FIGURE 8. Treatment with Fap1 blocking peptide decreases cytokine hypersensitivity of Bcr-abl⁺ primary murine myeloid progenitor cells. Primary murine bone marrow cells were transduced with a Bcr-abl expression vector or empty control vector. Cells were cultured under GMP conditions, deprived of cytokines, and stimulated with a dose titration of GM-CSF in the presence of Fap1-blocking SLV peptide or VLS control peptide. Proliferation was determined by incorporation of ³H-thymidine. Statistically significant differences between proliferation at a given GM-CSF dose are indicated by * ($p < 0.001$, $n = 3$).

decreased reporter activity in Bcr-abl⁺ transfectants in a manner that was not influenced by overexpression of WT Gsk3 β ($p \leq 0.03$, $n = 4$) (Fig. 7B). In contrast, Y216D-Gsk3 β expression significantly decreased Bcr-abl-induced TopFlash reporter activity ($p < 0.001$, $n = 4$) in a manner that was not altered by SLV peptide treatment ($p = 0.6$, $n = 4$) (Fig. 7B). In control experiments, expression of the FopFlash control vector was not influenced by transfection with vectors to express WT Gsk3 β , Y216D-Gsk3 β , or Bcr-abl, or by treatment with SLV peptide.

Fap1 Influences Cytokine Hypersensitivity of Bcr-abl⁺ Myeloid Progenitor Cells—These studies established a functional connection between increased Fap1 expression and increased β catenin activity in Bcr-abl⁺ myeloid cells. Because β catenin target genes include *c-myc* and *cyclinD1*, this suggests the possibility that increased Fap1 contributes to cytokine hypersensitivity of Bcr-abl⁺ myeloid progenitor cells. To investigate this, we used Bcr-abl-transduced murine GMP as described above. These cells (or control vector-transduced cells) were deprived of cytokines for 24 h, stimulated with a dose titration of GM-CSF in the presence of Fap1-blocking SLV peptide or VLS control, and then proliferation was evaluated by incorporation of ³H-thymidine (as in Ref. 13).

We found that treatment with SLV peptide significantly decreased proliferation of Bcr-abl⁺ cells at all tested concentrations of GM-CSF ($p < 0.001$, $n = 6$) (Fig. 8). In control experiments, expression of Bcr-abl was confirmed by Western blot analysis and real-time PCR (data not shown). These studies identify a functional consequence to increased Fap1 in Bcr-abl⁺ cells.

DISCUSSION

The leukemia stem cell in CML has been functionally characterized as a GMP with increased β catenin activity (8). We found previously that increased expression of Gas2 (a calpain inhibitor) stabilized β catenin in Bcr-abl⁺ myeloid progenitor

cells in an Icsbp-dependent manner (13). In this study, we identified another Icsbp-dependent mechanism for stabilizing β catenin protein in Bcr-abl⁺ cells. We found previously that decreased Icsbp-expression in Bcr-abl⁺ myeloid progenitor cells increased expression of Fap1 and impaired Fas-induced apoptosis (3, 4). In this study, we found that increased Fap1 in Bcr-abl⁺ cells also stabilized β catenin protein by participating in a multiprotein complex that includes Apc, Gsk3 β , and β catenin. We found that Fap1 dephosphorylated (inactivated) Gsk3 β . Inactivation of Gsk3 β decreased inhibitory serine/threonine phosphorylation of β catenin, thereby decreasing degradation of β catenin by the proteasome. Therefore, we have identified at least two Icsbp-dependent mechanisms that stabilize β catenin in CML.

Increased β catenin activity is associated with poor prognosis and disease progression in human CML. Because neither *CTNNB1* transcription nor Wnt signaling are increased consistently in CML (18), β catenin stabilization because of increased expression of Fap1 and Gas2 may be important to disease pathogenesis. Other investigators identified inactivating mutations of the gene encoding Gsk3 β that arose during disease progression in a murine CML model (28). These mutations were associated with decreased serine/threonine phosphorylation and degradation of β catenin. However, although decreased serine/threonine phosphorylation of β catenin was frequently associated with increased β catenin activity in human CML, *GSK3B* mutations were infrequent (28). These previous studies and our work suggest that multiple mechanisms stabilize β catenin in CML.

We previously identified Icsbp-binding negative cis elements in the *PTPN13* and *GAS2* promoters (3, 4, 10, 13). These homologous cis elements bind a protein complex that includes Tel and histone deacetylase 3 (Hdac3) (3, 13). Assembly of this complex on DNA required prebinding of Tel, which recruits the other two proteins. Interestingly, expression of Tel mRNA and protein was slightly increased in cells transduced with a Bcr-abl expression vector⁴. In human CML, Tel expression is not altered chronic phase, but decreases significantly with relapse or blast crisis³. This would facilitate an increase in Fap1 and Gas2 during disease progression in CML and stabilization of β catenin protein.

Increased β catenin activity facilitates the proliferative response of myeloid progenitor cells to hematopoietic cytokines by increasing expression of target genes such as c-myc and cyclinD1. β Catenin also contributes to Fas-resistance through increased expression of survivin, an inhibitor of apoptosis protein that inhibits caspase 3. Therefore, the net effect of increased Fap1 in CML is cytokine hypersensitivity and Fas resistance. This may contribute to persistence of CML LSC during tyrosine kinase treatment. Persistent CML LSC are hypothesized to be quiescent and, therefore, relatively indifferent to the antiproliferative effects of tyrosine kinase inhibitors. These cells may slowly expand over time, providing a reservoir for ongoing mutation and disease progression in CML.

Our studies suggest that blocking the action of Fap1 may decrease β catenin activity and overcome Fas resistance of Bcr-

abl⁺ bone marrow cells. This might have specific implications for eliminating the CML LSC in conjunction with a tyrosine kinase inhibitor. The observation that protein-protein interactions by Fap1 can be blocked by a tripeptide suggests that Fap1-PDZ domains might be a rationale target for small molecule development. This will be the focus of future studies in the laboratory.
